THE curriculum of the medical school has been a frequent topic of discussion in recent years. This association has devoted much attention to it and it continues in one form or another to occupy much of our time. A minimum curriculum requirement for a standard medical school is the basis for admission of a medical college to the Association of American Medical Colleges, and we determine the ability of the school to give efficient instruction within the limitations of this curriculum before we accept them for membership. It is clearly understood that we have fixed a minimal standard, but make no attempt to mould each school after a single fixed model. It is recognized that variations in personnel, in physical equipment and in local conditions make impossible the same type of teaching in every school. Were this possible, it would not be desirable, for no surer means of stopping progress could be conceived. It is the duty of each of us to try new methods and to share with others the experience so gained. From this alone can improvement come.

It has seemed to us at Harvard that medical schools have tended toward too great a rigidity of curriculum with too many separate examinations. This has resulted in leaving too little to the initiative of the student and in producing students too crammed with facts, too little able to think and to apply intelli-

¹Read at the meeting of the Association of American Medical Colleges held in Chicago, February 28, 1912.

gently their knowledge. For some years we have been attempting to change this condition, and various steps toward this end have been taken. The plan of fourth-year electives on which I reported to you at a previous meeting in connection with the concentration system of teaching^{*} was a step in this direction. This year we took another step in adopting a new plan of examination, which we believe will serve a twofold purpose, lessening the rigidity of the curriculum, and facilitating the correlation between the different subjects of the curriculum by placing before the student a new form of test for which he must seek to prepare himself.

The new plan of examination goes into effect with the class entering next year, and will not be applied to the classes in advance of that. Consequently four years will elapse before it has been tested in its entirety on one class. To at least five classes it should be applied before any opinion as to its real value can be given. At this time I can only explain the plan as we propose to try it. It may be of interest for you to know of it; perhaps some will care to apply it in their school. We believe it to be a distinct improvement and one that will lead to other changes in the curriculum. Already with this in view a committee has been appointed to restudy the curriculum and to propose any changes needed to meet these new conditions. The new plan of examination is to be regarded as part of a larger plan being worked out gradually and intended to improve our medical instruction.

The new plan of examinations is as follows. Written tests at the end of each course were formerly held. These are done away with, and in their place practical examinations are to be held, which are the only examinations conducted by the individual departments. The general committee in charge of examinations has supervision over the practical examinations, and they are to be a measure of the student's practical knowledge and skill. The student may choose whether he will take the practical examinations at the end of each

course, or near the time of the general examination. Practical examinations in all courses included in a general examination must be satisfactorily completed before the student will be admitted to the general examination. The practical examinations are to be graded and the marks so received are to make up 40 per cent. of the grade given on a general examination.

There will be two general examinations, one at the end of the second, the other at the end of the fourth year. Both will be partly written, partly oral. The subjects comprised in the first will be anatomy, histology and embryology, physiology, biological chemistry, pathology and bacteriology. Furthermore, this examination shall assume and require an elementary knowledge of physics, inorganic and organic chemistry and biology. The subjects comprised in the second general examination will be preventive medicine and hygiene, materia medica and therapeutics, medicine, surgery, pediatrics, obstetrics, gynecology, dermatology, syphilis, neurology, psychiatry, ophthalmology, otology and laryngology. For the first general examination the student may choose either June or September, for the second, either June or January. This difference in time is due to the custom at Harvard of awarding degrees both at mid-year and at Commencement. No student who fails to pass a general examination may repeat it within the calendar year in which he failed. No student will be permitted to begin the work of the third year until the first general examination has been passed. Consequently there will be no men carrying on work conditioned in previous courses.

The written part of each general examination will consist of questions selected and arranged by the committee on examinations from lists of questions submitted by the departments concerned. The written test will be divided into two or more periods of three hours each, but there will not be separate examinations on the various courses. The answers to the questions will be graded under the direction of the committee on examinations, not under the direction of a depart-

^{*} *Bulletin of American Academy of Medicine*, Vol. XI., No. 6, December, 1910.

ment. Thus in large measure the student is examined not by the man who gave the course. A single question may involve knowledge acquired in the work of several departments, and all questions are to be answered from this broader viewpoint and not from the viewpoint of any particular course. The grade so given on the written part of a general examination will make up 40 per cent. of the final mark for the general examination.

The oral part of each general examination will be conducted by boards of five members appointed by the committee on examinations, on each of which for the first general examination there must be at least one representative of the clinical branches, and for the second general examination at least one representative of the laboratory subjects. The board will determine by conference and vote the grade of the student, and the grade given on the oral part of a general examination will make up 20 per cent. of the final mark of the general examination.

This, then, is the plan for examination which we have voted to adopt. It is, as you see, a very considerable departure from the type of examination generally in vogue in medical schools. Practical examinations are given at present in most of the medical courses at Harvard. These will continue to be given. The present large number of written examinations will be reduced to two, to which are added two oral examinations, both planned to determine the student's comprehension, judgment and power rather than his detailed information. I will not occupy your time with any more minute description of the plan, and I will not enlarge upon what I consider to be its very great merits. We believe it to be a great improvement on our present system, but I will not engage in prophecy as to what it will accomplish; some years hence it can be reported again, and the reporter then will give you a criticism of its practical application with a statement of what modifications actual practise has required in it.

HENRY A. CHRISTIAN

BOSTON

DR. A. R. WALLACE AND THE UNIVERSITY
OF COLORADO

IN the general biology class at the University of Colorado it is customary to give a good deal of attention to the theory of evolution, and to the history of biological science. The class (about 135 students) of this year became much interested in the character and work of Dr. Alfred Russel Wallace, and took the liberty of sending him the following greeting on the occasion of his eighty-ninth birthday:

We, the students in the general biology class at the University of Colorado, ardent admirers of your work on evolution, send you respectful greetings on the occasion of your eighty-ninth birthday, wishing you health and happiness.

To this, Dr. Wallace replied in a letter dated January 12, 1912:

My dear Young Friends:

Thank you much for your very kind greetings. I am much pleased that so many of you are readers of my books. The wonders of nature have been the delight and solace of my life. From the day when I first saw a bee-orchis (*Ophrys apifera*) in ignorant astonishment, to my first view of the grand forests of the Amazon; thence to the Malay Archipelago, where every fresh island with its marvellous novelties and beauties was an additional delight—nature has afforded me an ever-increasing rapture, and the attempt to solve some of her myriad problems an ever-growing sense of mystery and awe. And now, in my wild garden and greenhouse, the endless diversities of plant life renew my enjoyments; and the ever-changing pageants of the seasons impress me more than ever in my earlier days.

I sincerely wish you all some of the delight in the mere contemplation of nature's mysteries and beauties which I have enjoyed, and still enjoy.

Yours very truly,

ALFRED R. WALLACE

HENRY WILSON SPANGLER¹

IN recording the death, on March 17th, of their friend and associate, Henry Wilson Spangler, Whitney Professor of Dynamical Engineering, the members of the University Faculties feel moved to give expression, how-

¹Minute adopted by the faculties of the University of Pennsylvania.

ever inadequately, to the great loss that has come to the university in the departure of one of her most efficient and devoted servants, and to their profound sense of personal bereavement in the death of a staunch friend and wise counsellor.

With the exception of a three-year period of service in the United States Navy, Professor Spangler has been a member of the faculty of the university since 1881. For more than a quarter of a century he has labored for the advancement of the important interests committed to his trust, with a singleness of purpose and a self-sacrificing devotion that served as an inspiration to his associates, from the humblest to the highest. Endowed with quick initiative, resourcefulness, courage and self-reliance, his qualities of leadership stood out at their best at times of emergencies, such as the destruction by fire of the old Mechanical Engineering Building, and the almost immediate and orderly resumption of activities in an incomplete, new building, with such facilities as could be quickly improvised. A strict and almost military disciplinarian, he was no less rigid in the standards which he applied to himself. The respect and admiration in which he was held by his students ripened into affection as they came to see him at closer range, and recognized the bigness of heart and the warmth of friendship that lay, poorly concealed, by a certain mantle of austerity. There were few graduates who failed to turn to him at some time for helpful counsel in the perplexities of later years, or who had failed to accept it, even though it ran counter to their own promptings. They had implicit confidence in his judgment, and knew that his advice sprang from genuine, almost paternal solicitude for their welfare, and that it was never given lightly. For some years before his death, he published, at his own expense, and sent monthly to every graduate of his department, a little pamphlet called the *Connecting Rod*, designed to give them information about the department and about each other, in a simple, unaffected way. Everything he did, for that matter, was done in a like manner, for none

had a more wholesome contempt for the vanities, affectations or shallow pretenses of man.

He possessed to a remarkable degree the faculty of perceiving clearly, and almost intuitively, the essential elements of a seemingly difficult problem or complex situation, and he was as quick in action as in perception. Few excelled him in the clear discernment of the fallacies of an argument or in the directness of the challenge of such fallacies. Of a thoroughly progressive bent, he did not allow himself to be carried away by the educational fads and follies of the hour. The business of education was, to him, a serious business, with which liberties were not to be lightly taken. Although his talents were frequently brought into requisition in outer circles, his duties as a teacher were, to him, ever of paramount importance, on which he allowed no professional obligations of a busy lifetime to trench unduly.

His university friends find it hard, indeed, to realize that his commanding figure has been seen upon the campus for the last time, and that in their councils his voice is stilled forever. None know better than they the sterling worth, the far-reaching significance of his performances in the service of the university, and especially of the department for which he had planned and labored so indefatigably, with such wholehearted devotion, and on which he has left the enduring impress of his rare powers.

THOMAS HARRISON MONTGOMERY¹

THE University of Pennsylvania has suffered an irreparable loss in the death of Dr. Thomas Harrison Montgomery, Jr., Professor of Zoology, who has done so much to illumine his favorite science, and who has endeared himself to his colleagues, both in this and other universities, at home and abroad.

Professor Montgomery was a son of the late Thomas Harrison Montgomery, for many years president of the American Fire Insurance Company of Philadelphia, who was a descendant of the Montgomerys of Eglinton, an

¹ Minute adopted by the faculties of the University of Pennsylvania.

ancient Norman family long settled in Scotland. He was also a great, great grandson of William White, D.D., LL.D., a graduate and trustee of the University of Pennsylvania, and first Bishop of the Protestant Episcopal Diocese of Pennsylvania. Professor Montgomery's mother, Anna Morton, was the daughter of Samuel George Morton, one of the founders of the science of craniology, and president of the Academy of Natural Sciences of Philadelphia, which is but this week celebrating its centenary.

Professor Montgomery was born in New York, March 5, 1873, and early manifested traits worthy of his ancestors. After two years as a student in the University of Pennsylvania, 1889 to 1891, he resolved to continue his studies in the University of Berlin, and secured his family's consent to the plan. His indefatigable industry immediately attracted the attention of his fellow-students, one of whom has related his astonishment at seeing a boy of eighteen working with unflagging zeal eighteen hours a day, with almost no rest or recreation, in the simultaneous acquisition of a difficult language and a group of the natural sciences. He received his degree of Ph.D. from the University of Berlin in 1894, and shortly after his return to America, was assigned by the University of Pennsylvania, a room for research work in the Wistar Institute, being the first person so appointed. During the next four years he labored with the same never failing energy, issuing a series of brilliant monographs upon some of the most difficult problems of zoology. In 1898 he was appointed assistant professor of zoology in the University of Pennsylvania. In 1903 he was called to the University of Texas as professor of zoology, but in 1908 he was recalled to take charge of the department of zoology in the University of Pennsylvania. Shortly afterward he was intrusted by the university with the chief responsibility for the planning and construction of the new Zoological Laboratory. Into this labor he threw himself with his usual untiring energy, giving personal attention to every detail. This building was completed and dedicated in 1911, and will

stand as a monument to his foresight and his executive ability.

The results of Professor Montgomery's research in the technically difficult problems of cellular structure and its relation to the phenomena of heredity and the determination of sex; in the activities, habits and development of spiders and birds; in the structure and development of various rotifers and insects and in the analysis of racial descent and of evolution, have been embodied in more than eighty published monographs. He has also published a volume, "Analysis of Racial Descent in Animals," 1906, and has left in manuscript a nearly completed work on cytology.

Professor Montgomery married, in 1901, Priscilla Braislin, daughter of John and Elizabeth Braislin, of Crosswicks, New Jersey. He is survived by his widow and three sons. Professor Montgomery was essentially a scholar and teacher, and for the greater part of his short life, his energies and interests were largely absorbed in his professional work, but he was much more; he was a man of the most sterling integrity, carrying into all the relations of life the sincerity, candor and faithfulness to truth which made him great in the realm of science. Those of his colleagues on the faculty, who came only professionally into contact with him, will, perhaps, remember these traits most vividly; but those of his friends who were privileged to know something of his home life, of his wholesouled devotion as husband, father and friend, will carry with them memories not less vivid and even more true of a noble and lovable man whose loss they will not cease to mourn.

We, his fellow-professors in the University of Pennsylvania, extend, therefore, to Mrs. Montgomery and the other members of his family, our sincere sympathy in their bereavement, and direct the secretary to transmit these resolutions to the public press and the scientific journals in testimony of Professor Montgomery's distinguished services to science, education and the University of Pennsylvania, and as an expression of the esteem

and regard in which he is held by all his friends and associates.

SCIENTIFIC NOTES AND NEWS

PROFESSOR RALPH STOCKMAN TARR, head of the department of physical geography at Cornell University, known for his important contributions to geology and geography, died on March 21, aged forty-eight years.

THE resignation of Charles Loring Jackson, Erving professor of chemistry at Harvard University, has been accepted to take effect on September 1. Professor Jackson has been on the teaching staff of the university for forty-four years.

DR. HENRY S. CARHART, late professor of physics in the University of Michigan, now retired on a Carnegie grant, has become connected with Throop Polytechnic Institute, in Pasadena, where he has taken up his home. He will have a special laboratory equipped with apparatus for his researches in the institute.

PROFESSOR JOHN F. HAYFORD, dean of the college of engineering of Northwestern University, has been appointed a research associate by the Carnegie Institution of Washington and has received a grant of \$6,000 in aid of his investigation of the laws of evaporation and steam flow.

M. BIGOURDAN, of the National Observatory, Paris, has been elected president of the Paris Bureau des Longitudes for the present year. M. Baillaud becomes vice-president and M. Andoyer, secretary.

THE Entomological Society of America has named Professor J. H. Comstock, Cornell University; Dr. Henry Skinner, Academy of Natural Sciences, Philadelphia; Dr. P. P. Calvert, University of Pennsylvania; Professor Herbert Osborn, Ohio State University; Professor Vernon L. Kellogg, Leland Stanford Jr. University, and Dr. W. J. Holland, director of the Carnegie Museum of Pittsburgh, as delegates to represent the society at the Second International Congress of Entomology, to be held at Oxford, England, from August 5 to 10, 1912.

PROFESSOR WILLIAM H. HOBBS, professor of geology, has been appointed by President Hutchins to represent the University of Michigan at the two hundred and fiftieth anniversary of the Royal Society of London, which will be held from July 16 to 18. Professor Hobbs has leave of absence for the coming year.

M. LIPPMANN, president of the Paris Academy of Sciences, will represent the academy at the celebration of the two hundred and fiftieth anniversary of the granting of the second charter to the Royal Society, which will be celebrated in July.

VICE-PRESIDENT T. J. BURRILL and Professor S. A. Forbes, of the University of Illinois, have been in the east attending the anniversary celebration of the Philadelphia Academy of Natural Science.

DR. ADOLF MEYER, professor of psychiatry in the Johns Hopkins Medical School, sailed on March 16 for Switzerland.

FREDERICK H. BLODGETT, Ph.D. (Hopkins '10), acting professor of biology and geology, has resigned from Roanoke College and assumed the duties of plant pathologist and physiologist at the Texas Experiment Station, College Station, Texas, on February 1. The work interrupted by the sudden death of Dr. Raymond H. Pond last summer will be resumed and some additional attention paid to plant diseases.

PROFESSOR ELLSWORTH HUNTINGTON, of Yale University, delivered three illustrated lectures on the "Desert," at the University of Michigan, beginning on Wednesday afternoon, February 28. In his first lecture he discussed Chinese Turkestan; Thursday, Palestine, and on Friday, March 1, "Historic Changes of the Climate in Relation to Geographical Effects."

On March 1, Dr. C. F. Hodge, professor of biology in Clark College, lectured before a convocation of the students and faculty of Indiana University, on "Civic Biology." In the evening Professor Hodge addressed the members of Sigma Xi and invited guests on the teaching of biology.

THE Philadelphia section of the American Chemical Society held a meeting at the John Harrison Laboratory of Chemistry, the University of Pennsylvania, on March 22, when Dr. L. H. Baekeland, research chemist of New York City, delivered an illustrated address on "The Theory and Technicology of Baekelite."

THE Chemical Club of the University of Illinois is giving a series of lectures on "The Field of Chemistry," endeavoring to help the younger student in chemistry to "find himself" and to show him the economic or "dollar and cents" situation. Professor A. V. Bleining, Professor Edward Bartow, S. W. Parr and H. S. Grindley will speak on the divisions in which they are interested.

THE twelfth lecture of the Harvey Society series was delivered by Dr. W. S. Thayer, of the Johns Hopkins University, on March 23, at the New York Academy of Medicine, the subject being "Malaria."

A COMMITTEE has been formed to erect a monument in honor of the late Dr. Janssen, the eminent French astrophysicist.

A BUST of Henri de Lacaze-Duthiers, the distinguished founder of the Zoological Station at Roscoff in Brittany, is to be erected upon one of the public squares at Roscoff, near the laboratory and fronting the sea. The execution of the bust, which is to be mounted on a shaft of granite, is to be entrusted to a Breton artist, M. Guilloic. Professor Yves Delage, 16 Rue du Docteur Berger, à Sceaux (Seine), acts as secretary of the committee in charge of the proposed monument.

EDWIN SABINE RENWICK, a well-known consulting engineer, son of James Renwick, professor of chemistry and natural philosophy at Columbia University, has died at the age of eighty-nine years.

THE International Association of Medical Museums will meet at the University of Pennsylvania, Philadelphia, on April 4, and the American Association of Pathologists and Bacteriologists at the same place on April 5 and 6.

THE Washington Academy of Sciences held a conversazione, with an exhibit of new and

interesting apparatus from the U. S. government and other scientific laboratories of Washington, in one of the rooms of the new National Museum on March 28.

PROFESSOR GEORGE D. HUBBARD, head of the department of geology in Oberlin College, has concluded plans for a field expedition for advanced students in connection with the work of the Oberlin Summer School. The party will leave at the close of the college year for West Virginia where New River cuts through the Appalachian Mountains, entering a territory containing examples of an unusually large number of geologic phenomena. Students furnish their own tents and equipment and camp during the entire trip, remaining in the field seven weeks and two days. This year for the first time women students will be admitted to the course. Mrs. Hubbard will accompany the expedition. Dr. Lynds Jones, associate professor of animal ecology, will conduct a field ornithological expedition to Point Pelee on Lake Erie, where special investigations will be made regarding bird migration.

THE twenty-third annual session of the Biological Laboratory of the Brooklyn Institute of Arts and Sciences will be held at Cold Spring Harbor, Long Island, New York, during the summer of 1912. Regular class work begins June 26 and continues for six weeks. Courses are offered in field zoology by Drs. Walter, Davenport and Kornhauser; in bird study by Mrs. Walter and others; in comparative anatomy in charge of Professor H. S. Pratt, Haverford College; cryptogamic botany in charge of Professor H. H. York, of Brown University; training course for field workers in eugenics in charge of Mr. H. H. Laughlin, of the Eugenics Record Office with lectures by Dr. C. B. Davenport. Facilities are offered for investigators. Further details are given in the announcement of the laboratory which may be obtained by addressing the director, Cold Spring Harbor, Long Island, N. Y.

ACCORDING to astronomical bulletins sent by Professor Edward C. Pickering, director of the Harvard College Observatory, the history

of the new star, Nova Geminorum, No. 2, is given below. Results obtained at Harvard are indicated by the letter (H). Sunday, March 10, Nova not visible on a plate showing stars of magnitude 11.5 (H). Monday, March 11, Nova well seen, magn. 5 (H). Tuesday, March 12, Nova discovered by Enebo, at Dombaas, Norway. Magn. 4. Wednesday, March 13, cablegram received at Harvard and distributed throughout America. In evening, Yerkes and (H) find spectrum of class F5, unlike other novæ. Hydrogen lines strong and dark. University of Michigan finds hydrogen lines bright and recession 5 km. from dark lines. Magn. 3.8 (H). Thursday, March 14, Yerkes and (H) find marked change in spectrum, hydrogen lines bright on edge of great wave length, like other novæ. Magn. 3.5 (H). Friday, March 15, photograph through thick clouds show nova faint magn. 5. Hydrogen lines very bright (H). Saturday, March 16, magn. 6, spectrum like normal nova spectrum. Nebulæ lines first seen. A star magnitude 14 in place of Nova on several early plates. A letter received at this observatory from Professor Frost states that a photograph of Enebo's Nova, taken on the evening of March 15, shows that "The bright lines of hydrogen are very broad and there are many other bright bands and dark lines throughout the spectrum. The bright H and K, at about their normal positions, are strong and broad and are crossed by very sharp, dark lines. The helium lines $\lambda 4923$ and $\lambda 5016$ are strong, both bright and dark. Helium $\lambda 4472$ is not conspicuous, but probably present." The following telegram, dated March 19, has been received from Dr. W. F. King, of the Ottawa Observatory: "Spectrum Nova Geminorum by Plaskett March eighteen seven tenths, numerous bright bands, maxima to red, and several narrow absorption lines, calcium, magnesium, iron. Velocity of recession about seventeen kilometers, magnitude about five and a half."

AMONG the changes recommended at the University of Chicago in the recent report of President Judson, is a readjustment of the time element in precollegiate courses by the School of

Education, a tentative scheme being as follows: "From the age of six to twelve, the elementary school; twelve to fifteen, the secondary school; fifteen to eighteen, the college (a junior college); the years following eighteen, the university. From the university at the age of twenty the student might take the baccalaureate degree, at twenty-one the master's degree, at twenty-two or three the various doctors' degrees. At the age of twenty-five or six if he enters on professional life he should be engaged in its practise, and by the time he is thirty he should be well established. In like manner at the age of twenty, if a student desires to enter on business he should be ready to do so, or if on the whole he prefers to enter business immediately from the three years of the college instead of entering the university at all he could do that with good training at the age of eighteen."

THE two federal bureaus engaged in the search for potash—the Bureau of Soils of the Department of Agriculture and the Geological Survey of the Department of the Interior—are in receipt of promising telegraphic news from their field representatives. A potash deposit of apparently great importance has been discovered at Borax or Searles Lake in the northwestern corner of San Bernardino County, California. This lake or playa is the last remaining pocket of a once much greater lake which has almost dried up and its central depression contains a large body of crystalline salts known to consist of common salt and sulphate and carbonate of soda with smaller quantities of borax. This salt body is saturated with brine, and interested persons stimulated by the governmental search for potash recently secured an analysis of old sample material from this brine. The result being significant, the lake was visited jointly by representatives of the Geological Survey and of the Bureau of Soils who took brine samples from six wells distributed over the salt flat. Analyses of these samples have been made by the cooperative laboratory at the Mackay School of Mines, at Reno, Nevada, and show an average of 6.78 per cent. of potassium

oxide (K_2O) in solution. The average salinity of the brine is 43.82 grams of solids per one hundred cubic centimeters. Comparison of the results indicates that the brines are nearly uniform throughout the flat. The probable importance of the deposits is due to the occurrence of the potassium salts in soluble form in a natural saturated brine, and under climatic and other conditions especially favorable to its separation and recovery by solar evaporation. Existing data give reasonable assurance that the brine-saturated salt body is at least 60 feet thick and covers an area of at least eleven square miles. Assuming the salt body to contain twenty-five per cent. by volume of the brine, the total amount of potassium oxide is estimated at over four million short tons. This estimate is believed to be very conservative, and the available tonnage may well be expected to exceed ten million tons, which would supply the country, at the present rate of consumption of potash, for thirty years. At any rate it appears that this locality constitutes a very important source of potash in probably readily available commercial form.

As a result of the recommendations recently made by a joint committee of the South African Association for the Advancement of Science and the Royal Society of South Africa, a general committee, says *Nature* quoting from *The South African Journal of Science*, has been constituted for the purpose of considering applications received for grants. Five grants, amounting in all to £250, were made at the first meeting of the committee held towards the end of last year. The grants were: (1) £40 to Professor W. A. D. Rudge, of Grey University College, Bloemfontein, to obtain a continuous record of the variations in the atmospheric gradient at various places, and to ascertain the relation between potential gradient and altitude, and between the diurnal variation of the gradient and the variation in the atmospheric pressure; (2) £45 to Professor A. Young, of the South African College, Cape Town, to investigate the occurrence of semi-diurnal, diurnal and spring and neap

tides observed in connection with an artesian well in the Cradock district; (3) £75 to Miss D. F. Bleek, to proceed to the Kalahari, so as to obtain phonographic records of the spoken language of the Bushman tribes north of the Orange and Vaal rivers; (4) £50 to Mr. R. N. Hall, to visit localities in Rhodesia, where Bushman paintings exist; (5) £40 to Mr. W. T. Saxton, of the South African College, Cape Town, for the purpose of studying the fungus diseases of trees in the Transkeian forests, investigating the ecology of the typical formations of the Transkeian territory, investigating a reported occurrence of the typical western province flora at St. John's, and to collect material for the study of the two genera of South African cycads, *Stangeria* and *Encephalartos*.

DR. G. D. THOMSON, of Canton, writes the *Geographical Journal* an account of some caves in the south of the Kwang-tung province, which, he says, have never yet been described by a European traveler. They lie about 250 miles southwest of Canton, by the route followed by boat. This involves the descent of the Canton River to the sea, and a coasting voyage west to the mouth of the Yeung-Kong River, which is ascended to the city of the same name. Here it is necessary to change boats, taking a native craft, pulled or poled by native men and women when the wind is contrary. In this way the walled city of Yeung-chou is reached, and the caves are situated a mile or more to the west of it. The chief cave is of large size and very beautiful. The hills in the immediate neighborhood rise abruptly from the plain in jagged rocky cliffs of totally different formation from the surrounding hills and mountains. At the entrance and on ledges high up the cliff there is a Buddhist monastery and shrines, presenting a gaudy appearance. From the outer chamber, which is beautified with stalactites and stalagmites, a flight of steps leads up to a second, cathedral-like cavern, not visible from the first. In this there is a stone table and stools, and shrines around the walls in niches, but the whole upper part is untouched by

man. At the far end a passage lets in the daylight from the opposite side of the hill. Dr. Thomson proposes to call this group of limestone caves by the name of Lord Kinnaid, in gratitude for the kindness shown to him and his brother during their college days. He refers also to various other groups of caves in the same province, which make of this part of China a veritable cave country. Though they have been described by Dr. Henry in his book called "Ling Nam," they are far from being generally known. They include the "Cathedral cave" (so named by Dr. Noyes, of Canton) and others to the north of that city on the Lien-chow and North rivers; and those in the neighborhood of Shiu-hing on the north bank of the main Si-kiang or West River.

IN connection with the graduate course in Highway Engineering at Columbia University, the following illustrated lectures have been given during the month of March by non-resident lecturers in highway engineering at 8:30 P.M.

March 4—"Sand-clay Roads and Oil-cement-concrete Pavements," Logan W. Page, director, United States Office of Public Roads, Washington.

March 8—"Mixing Plants for Bituminous Pavements," Francis P. Smith, chemical and consulting paving engineer, New York City.

March 11—"Comparison of Pavements," George W. Tillson, consulting engineer to the president of the Borough of Brooklyn, New York City.

March 15—"The Construction and Maintenance of Park Roads," John R. Rablin, Massachusetts Metropolitan Park Commission, Boston.

March 25—"The Organization of the State Highway Department of New York," John A. Bensel, New York State Engineer, Albany.

March 27—"Asphaltic Crude Oils and their Use in Highway Construction," Dr. Albert Sommer, Consulting Chemist, Philadelphia; or

"The Construction and Maintenance of European Roads," Arthur H. Blanchard, professor of highway engineering, Columbia University.

SEVENTY departments of the University of Wisconsin will be represented in the first exposition held at a university, which will

take place at that institution on April 19 and 20. Dr. Hermon C. Bumpus, business manager of the university, formerly director of the American Museum of Natural History, and Professors Stephen W. Gilman, of the course in commerce, C. K. Leith, of the geology department, and K. L. Hatch, of the college of agriculture, will comprise the faculty committee that will cooperate with 300 senior students in preparing for this exhibition. The engineering school will be represented by over 50 mechanical devices shown by its various departments. Among the interesting exhibits of the college of agriculture will be a model dairy and a model barn. Regular milking time will be announced so that visitors to the exposition can see mechanical milking machines in operation. The university bacteriological department will have an exhibit showing how many germs are afloat in the air of Madison, Milwaukee and Chicago. Plates will be put on the street corners in these cities for ten minutes and then will be put on exhibition to show the vast number of germs present in city air. Germs of hydrophobia and tuberculosis will also be on exhibition to be viewed through the microscope. How disease is transferred by handshaking will be shown by having a student with a germ-laden hand shake hands with fifty clean hands and then show the resulting contamination through the microscope. The home economics department of the university will be represented in the exhibition by a booth showing how to design and fit dresses and how to distinguish between good and bad taste in house decoration and furniture selection.

UNIVERSITY AND EDUCATIONAL NEWS

THE Harvard Graduate School of Applied Science has received from an anonymous donor a gift for a high-tension electrical laboratory. It will be built near the Jefferson Physical Laboratory. It is expected that the laboratory will have at its disposal an alternating current of 1,000,000 volts and a direct current of 100,000 volts.

ANNOUNCEMENT has been made of a gift of \$100,000 by Mr. J. P. Morgan to the Peabody College for Teachers. The trustees of the George Peabody fund have agreed to give an additional \$500,000 to the college, provided it collects \$1,000,000 by September 1, 1913.

Several fellowships in industrial chemistry will be offered by the chemical department of the North Dakota Agricultural College for the coming year. These fellowships, of the value of \$500, will be given for research work in connection with the paint industry.

MR. RUNCIMAN, president of the Board of Agriculture and Fisheries, has announced that in addition to the block grant of £1,300 a year given by the board to University College, Reading, in aid of agriculture and horticulture, and in addition to a further grant of £1,000 a year recently offered to the college in aid of advisory work among farmers, the Board of Agriculture would provide £2,500 a year and one half of the capital cost of a building with the object of establishing a dairying research station at the college, on condition that the grant of £2,500 a year was supplemented by £1,300 a year provided locally for the purpose.

THE degree of doctor of public health has just been established at the University of Wisconsin by vote of the regents upon recommendation of the university faculty. Candidates for this degree must hold the degree of doctor of medicine from medical schools of approved standing and must have spent at least two years in the study of sciences related to hygiene and public health subsequent to the regular medical course.

PROFESSOR GEORGE P. BURNS, who went to the University of Vermont two years ago as head of the department of botany, will not return to the University of Michigan, from which he had leave of absence.

THE Kaiser Wilhelm professor at Columbia University for the academic year 1912-13, who is nominated by the Prussian Ministry of Public Instruction, will be Phelix Krüger, Ph.D., professor of psychology at the University of Halle.

DISCUSSION AND CORRESPONDENCE

THE USE OF THE WORD "GENOTYPE"

IN a recent issue of SCIENCE, Bather¹ takes exception for the third time to the use of the word "genotype" by writers on Mendelism who apply the term in a sense quite different from that in which it was first proposed and has since been used consistently and continuously. It is obvious that Bather is not familiar with the situation here in America or surely he would be less caustic in his remarks. Certain of our biologists have been suffering from an attack of what might be called *Dementia Mendeliana*. Those of us who have escaped infection or who have recovered from the attack but who are surrounded by the sufferers are inclined to refer to their actions "less in anger than in sorrow."

Doubtless it is hard for a foreigner to understand the situation here in America. In biology no less than in politics we have "progressive" elements. And certain of these progressives have taken to themselves a name "geneticists." Also they have evolved a language. In doing this they have appropriated freely from the older language of mathematics, but not without exciting the suspicions of mathematicians. They have likewise appropriated certain terms from biological taxonomy, and since few if any of the leading "geneticists" are more familiar with taxonomy than with mathematics it is not strange that some of the borrowed terms have been misapplied.

There are few mathematicians who are familiar enough with biological matters to realize what liberties have been taken with their language, and few biologists sufficiently mathematical to be disturbed. It remains then for those biologists whose linguistic sensibilities are keen, to be annoyed if not irritated by the misapplication of biological terms in this new language.

But the present outlook is not without its hopeful features. It is to be observed that a movement toward segregation is taking place. The literature of this cult is not so widely

¹ SCIENCE, N. S., 35: 270.

scattered as formerly, though its volume remains large. During the last convocation week the American Association for the Advancement of Science was spared somewhat by the fact that most of the geneticists met in a city apart. Thus we venture the hope that in due time the segregation may become so complete that scientists may be free to peruse their favorite journals without risk of that offense to the finer sensibilities which results from seeing familiar words or characters abused.

UNIVERSITY REGISTRATION

TO THE EDITOR OF SCIENCE: Information received from the registrar of the University of Nebraska after the university registration statistics printed in the issue of SCIENCE for January 5, 1912, had gone to press, increase the enrollment of that institution as of November 1, 1911, from 2,733 to 3,459, as against 3,661 on November 1, 1910. The decrease is due to the fact that the affiliation relations of the university with the conservatory of music, which had existed for a number of years, were severed during the summer of 1911. The gain in attendance on the other departments was not large enough to offset the loss in music students.

In the net total registration of 4,889 students at Cornell University (excluding the summer session) there were included 477 students in the 1911 short-course in agriculture. These students are not in attendance at the university this academic year, although approximately that number of students are enrolled in the 1912 winter course. If these students are excluded from the Cornell registration, the winter attendance would be 4,412, instead of 4,889.

As for the figures of the University of Minnesota, in connection with which an explanation was given in a footnote, the situation is as follows: It has been customary for a long time to include in the total registration of the university the registration of the *School of Agriculture*, which is to be distinguished

sharply from the *College of Agriculture*, the latter being of collegiate grade, while the school has a three-year course of secondary grade. The students in attendance on the school, therefore, while not technically preparatory students in the sense that they are being fitted for college work, should really be classed as preparatory students—in any event they can not logically be regarded as college students. Subtracting from 4,807 students recorded as being in attendance at the university on November 1, 1911 (including the summer session), the 775 students in the school of agriculture, leaves a balance of 3,532 students of collegiate and university grade.

The figures for the Harvard School (787) included only the students in the summer courses in arts and sciences. There are, in addition, 278 students in science in the summer school of dental medicine. The total summer attendance thus becomes 1,065. Of these 115 students returned for work in the fall, the net total attendance at Harvard, inclusive of the summer session, thus being 5,674 instead of 5,426.

The University of Cincinnati submitted a table showing that its enrollment in all faculties on November 1, 1911, was 1,324 students, as against 1,416 on November 1, 1910, 1,364 on November 1, 1908, and 1,068 on November 1, 1903.

Taking account of these revisions, the net total attendance of 28 American universities as of November 1, 1911, including the summer session, but making due allowance for the summer session students who returned in the fall, is given in the following list.

1. Columbia	7,938
2. California	5,724
3. Harvard	5,674
4. Cornell	5,609
5. Michigan	5,452
6. Chicago	5,390
7. Pennsylvania	5,220
8. Wisconsin	5,015
9. Illinois	4,929
10. New York	4,055
11. Minnesota	3,773
12. Ohio State	3,587

13. Nebraska	3,459
14. Northwestern	3,438
15. Syracuse	3,307
16. Yale	3,224
17. Missouri	2,596
18. Texas	2,539
19. Kansas	2,265
20. Indiana	2,154
22. Iowa	1,967
21. Tulane	2,040
23. Stanford	1,648
24. Princeton	1,543
25. Western Reserve	1,331
26. Cincinnati	1,324
27. Johns Hopkins	1,057
28. Virginia	804

RUDOLF TOMBO, JR.

CONVOCATION WEEK MEETINGS

I HAVE read with interest two recent communications' in *SCIENCE* relative to the meeting place of the different scientific societies, with which I am heartily in accord. To me the only valid objection to holding these meetings at the time and place of the American Association is the tendency of the different meetings to conflict with one another. This difficulty should be to a great extent obviated if the executive committees of related societies (for example, zoologists, naturalists, anatomists) were to jointly arrange the program for their societies, allowing this program if necessary to include the day preceding or following those on which the general association meets. Certainly this difficulty was not obviated last year when the three societies above named met at Princeton, the meetings of zoologists and anatomists distinctly conflicting with each other. On the other hand, the great objections, as it seems to me, of holding these meetings at different places and at the same time is the entire loss of the benefits of the general association by those who wish to attend the sectional meetings. Speaking personally, I was much disappointed to miss the Sigma Xi convention at Washington last year in order to attend the zoologists' meeting at Princeton. To one living at some distance

¹ Morse, Max, *SCIENCE*, December 22, 1911.
Reese, A. M., *SCIENCE*, January 12, 1912.

from the heart of things a trip to the annual meetings involves a considerable sacrifice of time and money, and he feels like getting the largest return possible for such sacrifice, which was not possible for all of us with the meetings arranged as they were last year.

If the present policy of aloofness on the part of certain societies be deemed desirable in future, might it not at least be possible to arrange the sectional meetings so as not to conflict with those of the general association?

In the case of a society with eastern and central branches (viz., zoologists), where the majority of the members belong to the former branch, I believe it would be fair to all to hold two eastern meetings to each one in the central district, such meetings to be joint meetings of the two branches. Separate meetings by each branch seem to me undesirable, at least if such meetings are held at the same time, as was the case with the zoologists in 1910.

R. T. YOUNG

UNIVERSITY OF NORTH DAKOTA

THE TIDAL MACHINE

TO THE EDITOR OF *SCIENCE*: The undersigned desires to say that the machine described in the issue of this journal of February 23, 1912, under the name of "The Harris Tidal Machine" is the product of one of the bureaus of this government, the Coast and Geodetic Survey. The officials of that bureau, who are well acquainted with all the details of its development, from first inception to final completion, named it "The Coast and Geodetic Survey Tide Predicting Machine." Under that name it was described briefly in the *Journal* of the Washington Academy of Sciences, July 19, 1911, and more fully, with illustrations, in *Engineering News* of July 20, 1911.

E. G. FISCHER

WASHINGTON, D. C.,
February 26, 1912

REPLYING to Mr. Fischer's note concerning my article on "The Harris Tidal Machine" published in this journal on February 23,

1912, I wish to state that to the best of my knowledge and belief no "christening" of the machine has yet taken place; if it has, I am morally certain that the inventor was not invited to the ceremony. As the title "The Coast and Geodetic Survey Tide Predicting Machine" used by Mr. Fischer is not only lengthy but includes the Ferrell Machine used by the office for many years, the title under which I described it is logical in that it differentiates the Harris Machine from its predecessor, at the same time serving as a mark of honor to its inventor.

I wrote three letters to the Coast Survey Office protesting against the injustice done Dr. Harris in Mr. Fischer's article in *Engineering News* of July 20, 1911, and calling attention to the misstatements contained therein, requesting that the office publish suitable corrective notes. My letters were unanswered and I, therefore, laid the facts before the public in my article.

SAMUEL TIERNEY, JR.

QUOTATIONS

DR. WILEY AND THE BUREAU OF CHEMISTRY

On the 9th of April, 1883, I took the oath of office and entered upon the discharge of my duties as chief of the Bureau of Chemistry, in the Department of Agriculture. For the past twenty-nine years I have endeavored to discharge these duties according to the dictates of my conscience, the knowledge at my command and the obligations of my oath. In retiring from this position after so many years of service it seems fitting that I should state briefly the causes which have led me to this step. Without going into detail respecting these causes, I desire to say that the fundamental one is that I believe I can find opportunity for better and more effective service to the work which is nearest my heart, namely, the pure food and drug propaganda, as a private citizen than I could any longer do in my late position.

In this action I do not intend in any way to reflect upon the position which has been taken by my superior officers in regard to the same problems. I accord to them the same

right to act in accordance with their convictions which I claim for myself.

After a quarter of a century of constant discussion and effort, the bill regulating interstate and foreign commerce in foods and drugs was enacted into law. Almost from the very beginning of the enforcement of this act I discovered that my point of view in regard to it was fundamentally different from that of any of my superiors in office. For nearly six years there has been a growing feeling in my mind that these differences were irreconcilable, and I have been conscious of an official environment which has been essentially inhospitable.

I saw the fundamental principles of the food and drugs act, as they appeared to me, one by one paralyzed and discredited. It was the plain provision of the act and was fully understood at the time of the enactment, as stated in the law itself, that the Bureau of Chemistry was to examine all samples of suspected foods and drugs to determine whether they were adulterated or misbranded, and that if this examination disclosed such facts the matter was to be referred to the courts for decision.

Interest after interest, engaged in what the Bureau of Chemistry found to be the manufacture of misbranded or adulterated foods and drugs, made an appeal to escape appearing in court to defend their practises. Various methods were employed to secure this, many of which were successful. One by one I found that the activities pertaining to the Bureau of Chemistry were restricted and various forms of manipulated food products were withdrawn from its consideration and referred either to other bodies not contemplated by law or directly relieved from further control.

A few of the instances of this kind are well known. Among these may be mentioned the manufacture of so-called whiskey from alcohol, colors and flavors; the addition to food products of benzoic acid and its salts; of sulphurous acid and its salts; of sulphate of copper; of saccharin and of alum; the manufacture of so-called wines from pomace, chemicals and colors; the floating of oysters often in polluted waters for the purpose of making

them look fatter and larger than really they are for the purpose of sale; the selling of moldy, fermented, decomposed and misbranded grains; the offering to the people of glucose under the name of "corn syrup," thus taking a name which rightfully belongs to another product made directly from Indian corn silks.

The official toleration and validation of such practises have restricted the activities of the Bureau of Chemistry to a very narrow field. As a result of these restrictions, I have been instructed to refrain from stating in any public way my own opinion regarding the effect of these substances upon health, and this restriction has conflicted with my academic freedom of speech on matters relating directly to the public welfare.

These restrictions culminated in the summer of 1911 with false charges of misconduct made against me by colleagues in the Department of Agriculture, which, had it not been for the prompt interference on the part of the President of the United States, to whom I am profoundly grateful, would have led to my forcible separation from the public service. After the President of the United States and a committee of Congress, as a result of investigation, had completely exonerated me from any wrongdoing in this matter, I naturally expected that those who had made these false charges against me would no longer be continued in a position which would make a repetition of such action possible. The outcome, however, has not sustained my expectations in this matter. I was still left to come into daily contact with the men who secretly plotted my destruction.

I am now convinced that the freedom which belongs to every private American citizen can be used by me more fruitfully in rallying public opinion to the support of the cause of pure food and drugs than I could with the limited activity left to me in the position which I have just vacated. I propose to devote the remainder of my life, with such ability as I may have at my command and with such opportunities as may arise, to the promotion of the principles of civic righteousness and industrial integrity, which underlie

the food and drugs act, in the hope that it may be administered in the interest of the people at large, instead of that of a comparatively few mere manufacturers and dealers.

This hope is heightened by my belief that a great majority of manufacturers and dealers in foods and drugs are heartily in sympathy with the views I have held and that these views are indorsed by an overwhelming majority of the press and the citizens of the country. In severing my official relations with the Secretary of Agriculture I take this opportunity of thanking him for the personal kindness and regard which he has shown me during his long connection with the department. I can not leave the Bureau of Chemistry without expressing to my assistants of all grades my appreciation of their loyalty and devotion to me.—Statement by Dr. H. W. Wiley.

SCIENTIFIC BOOKS

A Descriptive Catalogue of the Higher Groups, Genera, Species and Subspecies of Birds known to occur in North America, from the Arctic Lands to the Isthmus of Panama, the West Indies and other Islands of the Caribbean Sea, and the Galapagos Archipelago. By ROBERT RIDGWAY, Curator of the Division of Birds. Part V. [Containing] Family Pteroptrochidæ—The Tapacolas. Family Formicariidæ—The Antbirds. Family Furnariidæ—The Ovenbirds. Family Dendrocolaptidæ—The Woodhewers. Family Trochilidæ—The Humming Birds. Family Micropodidæ—The Swifts. Family Trogonidæ—The Trogons. Washington: Government Printing Office. 1911. Bulletin of the United States National Museum. No. 50. Part V. "Issued November 29, 1911." 8vo. Pp. xxiii + 859; pls. xxxiii. Part V. of Ridgway's monumental work on the birds of north and middle America completes the first two thirds of this great undertaking, Part I. of which appeared in October, 1901. As Part IV. was issued in 1907, a longer interval than usual has elapsed between the appearance of Parts IV. and V., due in

part to interruptions by field work and illness, and in part to the preparation of matter originally intended, and even put in type for the present volume, but which it was found would too greatly increase its size. This matter, embracing the large family of Woodpeckers, will appear in Part VI, now in an advanced stage of preparation.

The present volume includes seven families, five of which are exclusively American, four of them being very numerous in species and subspecies. These are the Pterotochidæ (with only one species in the geographical area of the present works), the Formicariidæ (66 species and subspecies), the Furnariidæ (29 species and subspecies), the Dendrocolaptidæ (41 species and subspecies) and the Trochilidæ (174 species and subspecies). The other two families included are the Micropodidæ (25 species and subspecies) and the Trogonidæ (23 species and subspecies), the first of wide distribution throughout the world, the other common to all tropical regions. The same careful treatment in respect to technical details that has characterized the previous volumes is still maintained, as are the bibliographic references, which give at a glance the history of the species and higher groups as treated by preceding authors. The "keys" include many extra-limital genera and species, thus greatly widening the scope of the work as announced on the title page. There is a tendency to recognize as genera many groups usually treated as subgenera or altogether ignored; they are as a rule natural groups and their recognition in nomenclature is consistent with the present almost universal tendency to differentiate slight geographical forms as worthy of recognition as subspecies.

As heretofore, the work is based upon the material of the United States National Museum plus that of all the principal collections, private as well as public, in this country, the specimens examined in preparing the present volume numbering 14,358, of which about 6,000 are in the joint collections of the National Museum and Biological Survey. Of the more than 8,000 borrowed specimens, nearly all were furnished by three institutions,

the Museum of Natural History in New York, the Museum of Comparative Zoology at Cambridge and the Carnegie Museum of Pittsburgh. Through this system of cooperation the leading museums are benefited as well as the author, since the loaned material is returned bearing the identifications of the leading expert on the subject, and in addition the results of the author's investigations as here set forth are more comprehensive and rest on a firmer basis than would otherwise be possible. With even these resources the author has to regret that in several of the families a number of genera and very many species were not available for examination, so his "effort to bring order out of chaos can be considered as only partially successful."

While the scope of the work is restricted to the technicalities of the subject, references are made to nests and eggs "where some particular style of nest or coloration of eggs is characteristic of a group (family or genus), as a sort of accessory or supplemental group character." A paragraph is also given in the description of each family to a statement respecting the range in size, character of plumage, manner of life and nature of the food of the species, as well as their number and geographical distribution. Thus under the family Trochilidæ are some items of information not generally known even to all ornithologists, and much less to the general reader.

"Inhabitants exclusively of America, the Humming Birds constitute not only the most charming element in the wonderfully varied bird-life of the Western Hemisphere, but, also, without doubt, the most remarkable group of birds in the entire world. No other group of birds is so brilliant in plumage or so different from all others in their mode of flight and manner of feeding. The general habits of Humming Birds are not dissimilar to those of birds in general. They are both aerial and arboreal, but are unable to progress upon the ground or any flat surface by means of their legs and feet alone. They perch readily and frequently upon trees or bushes, or may even cling to rocks or other vertical surfaces; and

their nidification presents nothing that may be deemed peculiar or even specially characteristic. In their flight and manner of procuring their food, however, they differ strikingly from all other birds, in these respects closely resembling certain insects, especially the crepuscular hawkmoths (Sphingidæ). Their food, consisting mainly of small insects, but in part also of the nectar of flowers, is mostly gleaned from blossoms, before which they poise, with wings so rapidly vibrating as to be invisible except as a dim haze or halo partly surrounding the body and producing the humming sound from which these birds derive their vernacular name, the bill thrust inside the flower and the slender, semitubular tongue extended into the depths of the blossom. Some species, instead of feeding from flowers, glean their insect food from the bark of forest trees, following along the branches in suspended flight in the same manner that the others pass from flower to flower. In their feeding from flower to flower, Humming Birds, like bees, butterflies, and moths, perform the same office in the economy of nature as insects by transferring pollen from one bloom to another, and thus assisting in the fertilization of plants. In flying from one point to another, the flight of Humming Birds, while essentially direct, is usually more or less undulating, and so extremely rapid that the eye can scarcely follow. Often this flight is accompanied (at least in the case of males of some species) by a more or less remarkable screeching or grating sound, produced mechanically by some peculiarity of wing-structure.

"Diminutiveness of size and metallic brilliancy of coloring are the chief external characteristics of Humming Birds, though exceptions to both occur; and in these respects they, as a group, have no rivals. Unfortunately, stuffed specimens convey but a faint idea of their splendid coloring, for the perfection of their changeable refulgence can be fully realized only in the living bird, whose every change of position flashes to view a different hue—emerald green replacing ruby red, sapphire blue succeeding fiery orange, or either becoming opaque velvety black—according to

the angle at which the sun's rays touch the feathers, an effect which can only partially be imitated with the stuffed specimen by artificially changing its position with reference to the light. Many species have a spot of the most luminous or brilliantly metallic color (usually green) that it is possible to imagine on the forehead at the base of the bill, this spot being surrounded by the most intense velvety black—evidently to enhance the brilliancy of the ornament by contrast, just as a jeweler would, for the same purpose, display a diamond or other gem against a background of black velvet. Often there is a spot of brilliant color and one of a contrasting hue just below it, the result being that first one color, then the other, is flashed forth as the bird changes slightly its position."

The thirty-one plates give the structural details of bill, wings, tail and feet of each of the 121 genera, thus greatly facilitating identification. It is hoped that Part V. may be followed in due time by the remaining volumes of this invaluable work, so indispensable to all students of American birds.

J. A. ALLEN

The Hindu-Arabic Numerals. By DAVID EUGENE SMITH and LOUIS CHARLES KARPINSKI. Boston and London, Ginn and Company. 1911. Pp. vi + 160.

This book gives in compact form a readable and carefully prepared account of the numerous researches which have been made in the endeavor to trace the origin and development of the Hindu-Arabic numerals. Teachers of mathematics will welcome it, while students specializing in the history of mathematics will derive great help from the many bibliographical references to other publications on this subject. Like the arithmetician Tonstall the authors read everything in every language and spent much time in licking what they found into shape *ad ursi exemplum*, as the bear does her cubs. But it would not be a correct statement, were we to convey the idea that the book does not embody original research. In several cases the authors have been able to correct mistakes of earlier writers

and to add results of their own research. In a few instances this history appears to us incomplete and defective. This we shall endeavor to show in what follows.

The authors very properly give much attention to the study of routes of commercial travel. There is every reason to believe that the migrations of the numerals took place along commercial routes. The authors consider the possibility of an early influence of China upon India; they speak of trade routes and the interchange of thought by land and sea, between countries bordering on the Mediterranean and far-off India. They even point out early relations of Greece with China. In view of these careful studies it is singular that practically nothing should be said on the intercourse which did or did not exist between Babylonia and India during the centuries immediately preceding and following the beginning of the Christian era. They ignored a question which lies at the root of present-day speculations on the earliest traces of the principle of local value and the symbolism for zero. Of course, local value is considered by the authors in connection with the Hindu-Arabic numerals. Not to do so would be to examine the shell and ignore the kernel. Were these fundamental notions wholly of Hindu origin or were the rudimentary ideas relating to them imported into India from neighboring territory? In the book under review this vital question is not adequately discussed. The authors are correct in stating that the preponderance of authority has been in favor of the hypothesis that our numeral system, with its concept of local value and our symbol for zero has been of Hindu origin. But this conclusion is coming to be recognized as unsafe. The change of opinion that is taking place is voiced by two German authors of brief histories, Tropicke and Günther. In 1902 Tropicke said¹

Dass unser Positionssystem mit seinen Ziffern indischen Ursprunges ist, steht fest.

¹ "Geschichte der Elementar-Mathematik," I., p. 10.

In 1908 Günther said²

Man kann . . . sich den Vorgang vielleicht so denken, dass Indien von Babylon her die ersten schwachen Andeutungen des Stellenwertes empfing, sie in seiner Weise um- und ausbildete und später das reiche Geschenk des fertigen Positionssystems den Nachkommen jener Geber zurückerstattete.

The evidence in favor of a possible Babylonian origin is even stronger than as stated by Günther, for he was apparently unaware that symbols for zero had been found in Babylonia. These symbols are mentioned, but not adequately discussed by Smith and Karpinski, on page 51. The facts in our possession to-day are about as follows:

1. Two early Babylonian tablets, one probably dating from 1600 or 2300 B.C., use the sexagesimal system and the all-important principle of local value. It so happens that they contain no number in which there was occasion to use a zero.

2. Babylonian records from the centuries immediately preceding the Christian era give a symbol for zero which was apparently "not used in calculation." It consisted of two angular marks, one above the other, roughly resembling two dots, hastily written.

3. About A.D. 130, Ptolemy in Alexandria used in his "Almagest," the Babylonian sexagesimal fractions and also the omicron O to represent blanks in the sexagesimal numbers. The symbol was not used as a regular zero.

4. Strabo and others have described the trade routes by land and the trade between Babylonia and India, also the trade by sea.

5. Sexagesimal fractions were used by Hindu astronomers. Historians do not deny that the Indian sexagesimal fractions were of Babylonian origin.

6. The earliest form of the Indian symbol for zero was that of a dot, which, according to Bühler, was "commonly used in inscriptions and manuscripts in order to mark a blank." This early use of the symbol resembles somewhat the still earlier use made of symbols for zero by the Babylonians and by Ptolemy. Probably Aryabhata, in the fifth century

² "Geschichte der Mathematik," I., p. 17.

A.D., knew our zero. The earliest undoubted occurrence of our zero in India is in 876 A.D.

Were there overflows of Babylonian science into Greece and India? The question is pertinent. The possibility of overflows into India has been recognized not only by Günther, but by Nallino, who states that the Chaldeans of 100 B.C. (and even earlier) knew the sidereal year (estimated at 365 d. 6 hr. 13 m. 43 sec.) and that this knowledge probably passed from them to the Hindus and Persians. This statement is quoted by H. Suter with apparent approval.⁸ It seems to us that these facts point directly toward a summary of the case, somewhat as quoted above from Günther.

In recounting the earliest uses made of the Arabic numerals in Egypt and the Occident, reference is made to a trace on a pillar of a church in Egypt, giving the date 349 A.H. (= A.D. 961). Strange to say our authors completely ignore similar evidence, as given in the *Philosophical Transactions* of London. Why should this be? No less prominent a mathematician than John Wallis arrived at the conclusion that "their use in these parts was as old at least as . . . the middle of the eleventh century."⁹ Wallis refers to the "Mantle-tree of the Parlour Chimney at the dwelling House of Mr. Will. Richards, the Rector of Helmdon in Northampton-shire," bearing an inscription with the date "A^o Doⁱ M^o 133" (= A.D. 1133). Thomas Luffkin¹⁰ names a building in Colchester bearing the date 1090. These dates are of interest to an Englishman or an American. If they are to be rejected, it would seem that the reasons therefor should be set forth in a publication aiming to weigh minutely all respectable evidence. Smith and Karpinski make no mention of an earlier use than 1539 of the numerals in Great Britain.

In describing the different shapes of the

⁸ "Bibliotheca Mathematica," Vol. 5, 1904, p. 85.

⁹ *Philosophical Transactions*, No. 154, p. 399 (= *Abridgment*, Vol. I., 1705, p. 107).

¹⁰ *Philosophical Trans. Abridged*, Vol. I., 1705, p. 108.

zero in Europe the authors overlooked the curious use of *theta* θ to represent zero, found in the writings of Michel Rolle, and Eneström's note on this notation in "L'Intermédiaire des mathématiciens," II., 1895, p. 283.

It has been said of early American geologists that they crossed the western plains, eager to reach the Rocky Mountains, there to grapple with the problems relating to the geology of our land, that in so doing they neglected the geologic problems presented by the plains themselves. In the same way our authors hastened back half a thousand years to reach the conspicuously formative periods, and in so doing they forgot to take note of matters of interest connected with recent time, which for historical research is far from barren. Our authors note the different shapes which the numerals assumed among the Hindus, Arabs and Europeans of the Renaissance. But if I mistake not, interesting forms, worthy of study, are found in seventeenth and eighteenth century manuscripts, stored away in American libraries. It is of some interest that the figure 8 sometimes had the shape of our dollar mark written with a single downward stroke, thus, \$. I remember mistaking such an eight for a dollar mark and recognizing my error only when the sum given in the manuscript would not come out as represented, except on the supposition that the mark stood for 8. The authors point out anomalous combinations of the Hindu-Arabic and the Roman numeral symbols which occurred more or less accidentally in the fifteenth and sixteenth centuries, but they fail to notice a curious combination which occurs with surprising regularity in Spanish-American manuscripts during the three centuries preceding the beginning of the nineteenth century. Of this notation we shall speak in a separate article.

On page 28, line 10, the word "vertical" should be replaced by the word "horizontal." In the table of contents there is an omission such that the pronoun "their" in the line "Early ideas of their origin" refers to

"oriental names"; it should refer to "Hindu-Arabic numerals." The alphabetical index is not as complete as one might wish it to be.

FLORIAN CAJORI

COLORADO COLLEGE,
COLORADO SPRINGS, COLO.

A Laboratory Course in Physiology. By WALTER B. CANNON, A.M., M.D., George Higginson professor of physiology in the Harvard Medical School. Second edition. Published by Harvard University. 1911.

This is the set of loose-leaf laboratory notes and directions used in the course in physiology in the Harvard Medical School. It belongs to a class of works which have only begun to appear in recent years. It is not a general laboratory manual like the well-known handbook of Burdon Sanderson, or that of Stirling. Its scope is much narrower. While these works aimed to give, within the limits of their size, accounts of all ordinary physiological methods, the work before us, on the contrary, is merely a precise description of a particular course. Accordingly, it is limited to such methods as the facilities of the Harvard School allow. Within these limitations, however, it is excellent. It has already been adopted as the basis of the physiological course in a number of other institutions and contains much that is valuable and suggestive for the teaching of physiology anywhere.

The most striking defect of this "course" is that it contains far too much of the physiology of the frog and too little of the mammal. For the medical student direct personal experience in working with the circulation in one living cat or dog is worth two or three experiments upon the frog's heart, and a dozen upon the frog's leg. It is most unfortunate that the limitations which misguided humanitarians and anti-vivisectionists place upon the supply of cats in Boston should make it necessary to have the circulation in this animal worked out by the students in *groups of twelve*. This certainly falls far short of the important educational principle urged by Pearce that "the students should do it themselves." The reviewer knows from

personal experience that the largest number of students who can possibly take part in a blood-pressure experiment on one cat is five. If mammalian material were as abundant as it ought to be for such a course, the work on the frog here outlined could profitably be cut in half. Each group should number four or five students instead of twelve and should have, instead of one cat, six to ten.

Much of the work on the frog here given could be profitably replaced by experiments on man. Simple sphygmomanometers can be provided cheaply, and should be used for experiments on the students themselves on a much more extensive scale than is outlined in these notes.

The weakest point in the notes is the section on respiration. Only eight pages are devoted to this subject, while muscle nerve physiology receives eighteen. The progress in knowledge of respiration within recent years, for which we are indebted principally to Haldane and his pupils, has been made largely by experiments upon man. These experiments are ideally suited to a laboratory course. Among them may be mentioned that of voluntary forced breathing and the succeeding apnoea; that of the artificial production of Cheyne-Stokes breathing requiring for its demonstration merely a tin of soda lime and a long tube; and that of the duration of the voluntary holding of the breath without preparation, after forced breathing, after oxygen and after forced breathing and oxygen.

These, however, are merely criticisms of detail. In general this work is certainly by far the best of its kind that has yet appeared. No other educational institution in America, perhaps none in the world, in recent years has made so many valuable experimental contributions to the theory and methods of teaching as has Harvard. Among these contributions not the least valuable is the demonstration that science in general and physiology in particular can be, and ought to be, taught by laboratory methods. Originally conceived by Huxley and first practised in this country by Newell Martin at Johns Hopkins and by the

late Professor Bowditch at Harvard, this idea has finally developed in the hands of the latter's successor into the work before us. It has the particular merit of making available everywhere the results of twenty years of experience in the teaching of physiology at the Harvard Medical School.

YANDELL HENDERSON

YALE MEDICAL SCHOOL,
NEW HAVEN, CONN.,
February 27, 1912

*PLEISTOCENE MAN FROM IPSWICH
(ENGLAND).*

So much has been said in the public press concerning a human skeleton of reputed great antiquity recently found near Ipswich, England, that a request from the editor of SCIENCE alone sufficed to cause me to alter my original decision not to write anything on the subject until after I had seen the skeleton as well as the locality from which it came. On receipt of communications from Mr. J. Reid Moir, who found the remains and from Professor Keith, who is making a detailed study of them, it is possible for me to comply with the request without further delay.

The main facts are these. On October 6, 1911, Mr. J. Reid Moir, of Ipswich, was notified by Messrs. Bolton and Laughlin, local brickmakers, that one of their workmen, while removing surface clay to reach the underlying glacial gravel, had encountered human bones. Mr. Moir proceeded at once to the pit and found that a portion of a human skull still attached to a complete encephalic cast of boulder clay had been recovered. Recognizing the importance of the find, Mr. Moir removed the remainder of the skeleton in the presence of three gentlemen, Messrs. Woolnough (curator of the local museum), Canton, and Snell. In order to preserve the extremely fragile bones, the containing beds were removed with them. After this had been done, three geologists, Dr. J. E. Marr, F.R.S., Mr. W. Whitaker, F.R.S., and Mr. George Slater, F.G.S., were called to Ipswich to examine the section.

A sheet of hard chalky boulder clay of vary-

ing thickness is spread over East Anglia, overlying stratified mid-glacial sands. Between these deposits and at a depth of only four and one half feet the skeleton was found. Was it interstratified? This question will probably never be answered to the satisfaction of all. According to Mr. Moir, a "most careful examination of the section before the disinterment took place showed clearly that no signs of any previous digging were visible, the clay above the skeleton appearing to be in every way the same as that which extended for some distance on each side of it." The presence of a calcareous band immediately underneath the skeleton was noted as well as the fact that it "extended more or less continuously on either side of the spot where the remains were found"; and it is pointed out by Mr. Moir that if a grave had been dug through the boulder clay, rain water percolating through the loose grave filling would have dissolved away the calcareous deposit. One of the best bits of evidence is that the skeleton was partly embedded in glacial sand and partly in boulder clay; "this sand showed clearly lines of stratification and was conformable with that underlying it."

On the other hand Mr. George Slater, one of the three geologists called to view the place, but not until after the bones had been removed to London, looks upon the site as highly unsatisfactory. Considering the loss by infiltration he would not expect to find distinct signs of a grave after a lapse of some thousands of years. The position on the side of a valley points to the possibility of hill wash or re-deposited boulder clay.

It was a wise precaution from every point of view to remove the matrix with the skeleton. This was done in blocks which were forwarded to Professor Arthur Keith at the Museum of the Royal College of Surgeons, London. Here each block was impregnated with a solution of gelatine, after which the bones were exposed by piecemeal removal of the overlying boulder clay, but were still left in situ on the underlying glacial sands. According to Professor Keith the whole skeleton was represented, its various parts being in

their proper position one to the other. It rested on its right side with the head bent forward, so as almost to reach the knees. The right arm was flexed beneath the body, the right hand resting under the right leg. The left arm was even more acutely flexed, with the elbow gripped between the knees and the left hand turned against the left shoulder. That the position of the Ipswich skeleton resembled somewhat the contracted posture so common to neolithic burials was recognized by Professor Keith, who believes, however, that this position does not necessarily mean burial; in other words, that it could have been assumed by the body at death without the intervention of intentional forces.

The right side of the skeleton in contact with the glacial sands was much better preserved than the left. The latter being embedded in the boulder clay, was most subjected to the destructive effects of roots as well as the action of the clay itself. The roots even penetrated the glacial sands and their effects on the skull and pelvis were marked. The corroding effects of the boulder clay (sandy, chalky loam) played havoc with the soft spongy portions of the skeleton, which are now represented by dense clay with here and there fragments of bone. The only complete bones recovered were those of the right hand.

The skeleton is that of a man about five feet ten inches in height and forty to fifty years of age. In addition to the complete brain cast (of boulder clay) there remain a "fragment of the frontal bone sufficient to show the characters of the forehead, parts of both temporal bones, with the joints of the mandible, and fragments of the parietal and occipital bones."¹ Nine of the teeth were recovered; these differ in no way from the teeth of neolithic man. Judging from the skull fragments and the brain cast, Keith concludes that the head did not differ essentially from that of modern Europeans except that the

maximum width of the skull is situated rather far back, recalling in this respect alone the Neanderthal race. With the exception of the lower leg bones (tibia and fibula) and the upper arm bone or humerus, the limb bones are of the modern European type. The tibia lacks the sharp anterior crest or shin of modern man, and in this suggests the Neanderthal type, but not in respect to size and general shape.

If the skeleton does not represent a burial and if the chalky sandy loam at this point is a part of the original mantel of boulder clay, then the man of Ipswich is the earliest yet found with the exception of *Homo heidelbergensis* (*Pithecanthropus* not being considered as *Homo*). It would correspond to the latest colithic horizon, the so-called Mesvinian, and would thus be somewhat older than the man of Galley Hill, provided the latter is properly dated. But as I pointed out in a recent article² there is room for doubt as to the age of the Galley Hill skeleton. From the foregoing account it would seem that the age of the Ipswich skeleton is also still an open question. The importance of having expert witnesses present at the disinterment in discoveries of this class was perhaps never better exemplified than at Galley Hill and Ipswich. Their absence will, it is feared, always leave the shadow of a doubt as to the age of the skeletons in question; and doubt is a serious handicap in matters of such scientific import. If both these specimens are correctly dated, then there lived as contemporaries in Europe for a long space of time two somatologically distinct races—a primitive type represented by the Mauer mandible, Neandertal, Spy, Chapelle-aux-Saints, La Quina, etc.; and a modern type represented by Ipswich, Galley Hill, and possibly Bury St. Edmunds. This is by no means impossible, in fact might have been the case. Either Ipswich or Galley Hill would alone be sufficient to prove it so, if all doubt as to age were removed. Until the full reports of Professor Keith, Mr. Moir, and the three geologists have been published, final

¹From the report of an "inquest" in Ipswich February 21, which according to Mr. Moir gives "a very good account of the human remains" he had found.

²"Somatology and Man's Antiquity," *Records of the Past*, X., 329, November-December, 1911.

judgment on the Ipswich case must of course be suspended. If the modern type of man did actually live in Mindel-Riss interglacial times, a Pliocene chipper of flint would certainly not look out of place.

GEORGE GRANT MACCURDY

YALE UNIVERSITY,
NEW HAVEN, CONN.

THIRD LIST OF GENERIC NAMES FOR THE
"OFFICIAL LIST OF ZOOLOGICAL
NAMES"

9.¹ The following generic names of animals reported as parasites of man have been submitted to the International Commission on Zoological Nomenclature, by the Helminthological Society of Washington, for inclusion in the "Official List of Zoological Names":

CESTODA:

- Davainea* R. Blanchard & Railliet, in R. Bl., 1891t, 428-440, type *proglottina* (in chickens; France).
Diplogonoporus Læunberg, 1892a, 4-16, type *balanoptera* (in *Balanoptera borealis*; Finnmarken).
Dipylidium Leuckart, 1863a, 400, type *caninum* (in dogs; Europe).
Echinococcus Rudolphi, 1801a, 52-53, 55, type *granulosus* (in sheep; Europe).
Tania Linnæus, 1758a, 819-820, type *solum* (in *Homo*; Europe).

NEMATODA:

- Ancylostoma*² [Dubini, 1843a, 5-13] emendation Creplin, 1845a, 325, type *duodenale* (in *Homo*; Italy).
Ascaris Linnæus, 1758a, 644, 648, type *lumbrioides* (in *Homo*; Europe).
Dracunculus "Kniphof, 1759, 12" [not verified]; Gallandat, 1773a, 103-116, type *medinensis* (in *Homo*).
Gnathostoma Owen, 1836f, 123-126, type *spinigerum* (in *Felis tigris*; London).
Necator Stiles, 1903y, 312, type *americanus* (in *Homo*; U. S. A.).
Strongyloides Grassi, 1879f, 497, type *intestinalis* = *stercoralis* (in *Homo*).
Trichostrongylus Looss, 1905o, 413-417, type *retortaeformis* (in *Lepus timidus*; Europe).

¹ Paragraphs are numbered continuously with the earlier lists.

² See Art. 19, and Opinions 26, 27, 34 and 36.

GORDIACEA:

- Gordius* Linnæus, 1758a, 644, 647, type *aquaticus* (free; Europe).
Paragordius Camerano, 1897g, 368, 399-402, type *varius* (free; U. S. A.).

ACANTHOCEPHALA:

- Gigantorhynchus* Hamann, 1892d, 196, type *echinodiscus* (in *Myrmecophaga jubata*, *M. bivittata*; Brazil).

10. The undersigned secretary presents the following generic names for definite rejection from the "Official List," on the ground that they are preoccupied (see Art. 34):

TEMATODA:

- Acanthocephala* Dies., 1858, not Laporte, 1832.
Acroactyla Staff., 1904, not Hal., ante 1846.
Anadasmus Looss, 1899, not Walsingham, 1897.
Anisogaster Looss, 1901, not Deyr, 1863.
Astia Looss, 1899, not Koch, 1879.
Baris Looss, 1899, not Germ., 1817.
Brachymetra Stoss., 1904, not Mayr, 1865.
Creadium Looss, 1899, not Vieill., 1816.
Crossodera Duj., 1845, not Gould, 1837.
Eurycalum Brock, 1886, not Chaudoir, 1848.
Euryoma Duj., 1845, not Gistl., 1829.
Leioderma Staff., 1904, not Will.-Suhm, 1873.
Leptalea Looss, 1899, not Klug, 1839.
Leptosoma Staff., not Leach, 1819.
Levinnesia Stoss., 1899, not Mesnil, 1897.
Macraspis Olss., 1868 or 1869, not McL., ante 1835.
Megacetes Looss, 1899, not Thomas, 1859.
Microscapha Looss, 1899, not LeConte, 1866.
Polyorchis Stoss., 1892, not Agassiz, 1862.
Polysarcus Looss, 1899, not Fieb., 1853.
Spathidium Looss, 1899, not Duj., 1841.
Stomylus Looss, 1899, not Fahræus, 1871.

NEMATODA:³

- Acanthophorus* Linst., 1876, not Serv., 1832.
Acanthosoma Mayer, 1844, not Curt., 1824.
Aspidocephalus Dies., 1851, not Motsch, 1839.
Brachynema Cobb, 1893, not Fieb., 1861.
Cephalacanthus Dies., 1853, not Lac, 1802.
Cephalonema Cobb, 1893, not Stimps, ante 1882.
Chatosoma Claparède, 1863, not Westwood, 1851.
Cheiracanthus Dies., 1838, not Agassiz, 1833.
Cochlus Zed., 1803, not Humph., 1797.
Conocephalus Dies., 1861, not Thunb., 1812.

³ This list contains a few names of organisms which are not Nematoda, but which have been classified as such at one time or another.

Cystocephalus Rail., 1895, not Léger, 1892.
Diceras Rud., 1810, not Lam., 1805.
Dipeltis Cobb, 1891, not Pack., 1885.
Discophora Vill., 1875, not Boisd., 1836.
Eucampitus Duj., 1845, not Chevr., 1833.
Eurystoma Marion, 1870, not Raf., 1818.
Fimbria Cobb, 1894, not Bohadsch, 1761.
Hoplocephalus Linst., 1898, not Cuv., 1829.
Leptoderes Duj., 1845, not Serv., 1839.
Litosoma Ben., 1873, not Douglas & Scott, 1865.
Mitrephorus Linst., 1877, not Schoenherr, 1837.
Oxyroma Schneid., 1866, not Gerv., 1849.
Oxystoma Buetschli, 1874, not Dum., 1806.
Oxyurus Lam., 1816, not Raf., 1810.
Paradozites Lindem., 1865, not Goldf., 1843.
Pelodytes Schneid., 1860, not Fitz., ante 1846.
Pterocephalus Linst., 1899, not Schneid., 1887.
Ptychocephalus Dies., 1861, not Agassiz, 1843.
Rhabdogaster Metschnikoff, 1867, not Loew., 1858.
Rhabdonema Leuck., 1883, not Kuetzing, 1844.
Rhabdonema Perr., 1886, not Kuetzing, 1844.
Rhytis Mayer, 1835, not Zed., 1803.
Spilophora Bast., 1865, not Bohem., 1850.
Spinifer Linst., 1901, not Raf., 1831.
Spira Bast., 1865, not Brown, 1838.
Spirura Dies., 1861, not E. Bl., 1849.
Trichina Owen, 1835, not Meig., 1830.
Trichoderma Greef, 1869, not Steph., 1835.
Trichodes Linst., 1874, not Herbst, 1792.
Triodontus Looss, 1900, not Westwood, 1845.
Tropidurus Wieg., 1835, not Neuwied, 1824.
Tropisurus Dies., 1835, not Neuwied, 1824.

GORDIACEA:

Paragordius Montgomery, 1898, = Camerano, 1897.

ACANTHOCEPHALA:

Arhynchus Shipley, 1896, not Dejean, 1834.
Neorhynchus Ham., 1892, not Sclater, 1869.

11. The names in question are published for the information of all persons interested. Objection to the proposed action should be filed with the undersigned secretary not later than January 1, 1913, together with ground upon which objection is based.

12. The above names will be forwarded immediately to the International Commission on Medical Zoology, and to the special sub-committees in the groups in question for special report.

13. The list will be forwarded about July 1, 1912, to the International Commission on

Zoological Nomenclature, and the secretary expects to call for a vote on these names at the next regular meeting of the commission, in the summer of 1913.

14. The secretary takes this opportunity to state that his policy is to bring into the list a number of names upon the adoption of which no difference of opinion seems to exist, and to reject a large number of preoccupied names, before he submits for study the names upon which differences of opinion are expressed by authors.

O. W. STILES,

on Zoological Nomenclature
 Secretary International Commission

SPECIAL ARTICLES

ON THE ORIGIN OF A PINK-EYED GUINEA-PIG WITH
COLORED COAT¹

THE rediscovery of Mendel's law in 1900 with the immediate and striking verifications which it received from both animal and plant breeders gave great impetus to the mutation theory of De Vries, and secured wide acceptance of the idea advanced earlier by Galton and Bateson that new organic forms arise only as discontinuous variations, in the production of which continuous or fluctuating variations have no part. An extreme form of this idea has been ably advocated by Johannsen in his pure-line conception of heredity. This has met with a reception so hearty that it is now endangered chiefly by the zeal of its adherents, who seem to some of us to be carrying the doctrine to ridiculous lengths. They can see nothing but pure lines in heredity of any sort; selection is wholly rejected except as an instrument for the sorting out of genes. Possibly this is the correct interpretation of the action of selection, but if so it will be found necessary to invoke the existence of multiple and subsidiary genes to such an extent that continuous and discontinuous variation will become practically indistinguishable. I am inclined, therefore, to question the validity of

¹In the investigation described in this paper the author was aided by a grant from the Carnegie Institution of Washington, for which grateful acknowledgment is here made.

a hypothesis which has to be carried to such lengths, and I think this view is shared by many whose experience in breeding work has been very extensive.

Webber has somewhere expressed the view, I am sure verbally and I think also in his publications, that sport variation is more likely to occur in connection with repeated selection and in the same general direction as the selection. This view, if correct, is highly important. A case which may be considered to support it has recently occurred in the breeding experiments in progress at the Bussey Institution.

In mice, rabbits and cats, a dull black variety occurs which is known by fanciers as blue. The optical effect called blue is in such cases the result of a diminished number of black pigment granules in the fur. Fanciers have long desired to obtain a similar variety among guinea-pigs, but thus far without much success. Some eight years ago I became interested in the problem and began experiments which have continued to the present time. Knowing that Andalusian blue fowls are heterozygotes of black and white, I tried to produce a similar modification in guinea-pigs by cross-breeding. I found that crossing black with white gave results which varied in character with the white strain used. A sooty or "Himalayan" albino strain which by other experiments was shown to transmit intense black pigmentation produced no diminution of black in the heterozygotes. A very lightly pigmented albino which was found to transmit light yellow ("cream") in crosses produced heterozygotes with a much duller black, but not of the desired blue tone. In other words, albinos in crosses with black were found to breed exactly like the colored strains from which they were extracted. As the cross with a cream strain had produced the lightest black animals thus far obtained, I confined my further experiments to crosses with this cream strain or with albinos derived from it. In each generation the lightest heterozygous blacks were crossed with the lightest creams (or albinos). By this process a very considerable reduction in the amount

of pigment in the fur was secured. The hairs of the black individuals were now dull black at the tip only; elsewhere the hair was sooty cream colored, indicating a great quantitative reduction of the pigments, both black and yellow. These peculiar black individuals we may for convenience henceforth call "blue." Blue parents mated with cream ones have in the past two years produced 17 blue, 15 cream and 13 white young, the Mendelian expectation being 3 blue: 3 cream: 2 white, if all parents are heterozygous for albinism. In a mating of this sort a few weeks ago (December 2, 1911) a blue mother gave birth by a cream male to a female young one which closely resembles an albino, its coat being in general white and its eyes pink, but on the right side of its head and on the hips are spots of blue. As in the pink-eyed mouse, the color of the fur is decidedly pale. In the iris of each eye may also be seen a faint pigmented streak. It is noteworthy that the pink-eyed mouse also has traces of pigment in its eyes.

The genetic behavior of pink-eyed mice shows that the pink-eyed variation is due to modification (or partial loss) of some factor necessary for the production of the full pigmentation. This factor, however, is not the color factor (*C*) which albinos lack, nor the yellow (*Y*), brown (*Br*) or black (*B*) factors, nor yet the agouti (*A*) factor, since with each of these and without it the pink-eyed variation may form distinct combinations. For the same reason it can be shown to be distinct from the condition of spotting with white.

It is noteworthy that the race of guinea-pigs in which the pink-eye variation has appeared is one in which a reduction of the amount of pigmentation was being attempted by a systematic selection, and was being actually obtained. The pink-eye variation would seem, therefore, to be merely a particular long step in the general course of modification which this race was undergoing directed by artificial selection. If so, it has probably been brought about by the modification of the *same* color factor or factors that have undergone modification in the blue race. This idea

will be put to an experimental test. If found correct, the suggestion will offer itself that a causal relationship may possibly exist between the *little* steps taken under selection, and the longer one appearing as a mutation.

The variation described in this paper made America on a collecting expedition. My associate, Mr. C. C. Little, was then in charge its appearance during my absence in South of the experiments. He at once recognized the importance of the variation from a theoretical standpoint and has given especial care to its preservation. For this I wish both to thank and to congratulate him. A less discriminating observer might easily have mistaken this animal for an albino with soiled fur.

W. E. CASTLE

LABORATORY OF GENETICS,
BUSSEY INSTITUTION,
FOREST HILLS, MASS.,
February 8, 1912

**THE AMERICAN ASSOCIATION FOR THE
ADVANCEMENT OF SCIENCE
SECTION B—PHYSICS**

THE annual meeting of Section B of the American Association for the Advancement of Science was held with the American Physical Society at the Bureau of Standards, Washington, December 27-30, 1911. Four forenoon sessions and three afternoon sessions were held. Of these, two were "general interest" sessions in charge of the officers of Section B and five were occupied with research papers, in charge of the American Physical Society. In all seventy-four papers were presented and one symposium held. Eight papers were presented by title only.

The presiding officers were Professor R. A. Millikan, vice-president of Section B, and Professor W. F. Magie, president of the Physical Society. At a short business session of the section Professor Theodore Lyman was elected to represent the section on the council, Professor C. E. Mendenhall a member of the sectional committee (for five years) and Professor F. A. Saunders a member of the general committee.

All sessions were held in a large laboratory of the Bureau of Standards. The attendance at several was about two hundred and for most others exceeded one hundred. It was probably the largest and most representative gathering of physicists

ever held in America. In each of the three days when two sessions were held the scientific staff of the bureau generously provided a fine lunch for all in attendance.

The address of the retiring president of the association was of special interest to physicists this year. It was given on Wednesday evening in the assembly hall of the new National Museum by Professor A. A. Michelson on the subject "Recent Progress in Spectroscopic Methods."

On Friday evening a subscription dinner was given by the Philosophical Society of Washington in honor of Section B and the American Physical Society at the Shoreham Hotel. This was attended by about one hundred and was a most delightful occasion. Dr. E. B. Rosa, the retiring vice-president, acted as toastmaster and Professor A. A. Michelson, the retiring president of the association, was among the guests of honor.

Among the members of the association who were elected fellows by action of the council at this meeting are the following members of Section B: H. A. Wilson, Frank Wenner, Fay C. Brown, E. A. Harrington and W. J. Fisher.

The officers for the next annual meeting, to be held in Cleveland during the convocation week of 1912-13, are as follows:

Vice-president and Chairman of Section B—Professor A. G. Webster, Clark University.

Retiring Vice-president—Professor Robert A. Millikan, University of Chicago.

Secretary—Dr. W. J. Humphreys, U. S. Weather Bureau, Washington.

Member of Council—Professor Theodore Lyman, Harvard University.

Sectional Committee—R. A. Millikan, A. G. Webster, W. J. Humphreys, A. P. Carman, G. F. Hull, E. L. Nichols, A. Zeleny, C. E. Mendenhall and the president and secretary of the American Physical Society.

The two general-interest sessions in charge of Section B were held on Thursday, December 28. At the morning session Professor W. F. Magie, of Princeton, delivered the presidential address of the American Physical Society on "The Primary Concepts of Physics." This is given in full in the February 23 issue of SCIENCE. The remainder of the morning session was devoted to a symposium on "The Ether," led by Professor A. A. Michelson. Professors A. G. Webster, E. W. Morley, W. S. Franklin, D. F. Comstock and G. N. Lewis took part in the discussion. The significance and place of the principle of relativity was of course given principal attention and some difficulty was

experienced in finding common ground upon which to stand. At the afternoon session of the same day the retiring chairman of Section B gave his vice-presidential address upon "The Work of the Electrical Division of the Bureau of Standards." This is printed in full in the January 5 number of SCIENCE. Then followed an address by Professor H. A. Wilson, on "The Structure of the Atom," and by Director S. W. Stratton, on "The Work of the Bureau of Standards."

The following are abstracts of these addresses:

The Structure of Atoms: Professor H. A. WILSON, McGill University.

The essential constituent of matter appears to be electricity; recent researches, experimental and theoretical, suggest that electricity is in fact the only constituent of matter.

Free negative electrons can be obtained from almost any form of matter by heating, by the action of ultra-violet light or in other ways. The optical properties of matter are now explained by the presence of negative electrons; the Zeeman effect and dispersion may be specially mentioned. Many of the electrical and thermal properties of metals have been satisfactorily explained by supposing that metals contain negative electrons which move about inside them like the molecules of a gas.

Negative electrons must therefore be regarded as a universal constituent of all forms of matter. These electrons, moreover, are with good reason believed to be simply minute particles of negative electricity of much less than atomic size.

Electrically neutral matter must contain as much positive electricity as negative; it is clear, therefore, that all matter must also contain positive electricity. One of the most important results of recent electrical researches is the fact that while free negative electrons can be easily obtained from any kind of matter, positive electricity is always associated with at least one atom and never appears in the form of positive electrons. Positively charged molecules seem to be in all cases the result of the removal of negative electrons from neutral molecules. Since it appears that all negative electricity is made up of equal particles and since it is very probable that any atom can be exactly neutral it follows that the amount of positive electricity in any atom must be an exact multiple of the charge of one negative electron. This makes it probable that positive electricity is also made up of equal parts, but so far they have not been obtained free.

The absence of effects due to the earth's motion

relative to the ether can be explained on the electromagnetic theory if it is supposed that this theory covers all phenomena. This appears to be a strong argument in favor of the purely electrical nature of matter.

It will be convenient now to mention the chief electrical theories of atomic structure which have been proposed.

According to Sir J. J. Thomson, atoms consist of solid spheres of positive electricity inside which negative electrons move about freely. If the sphere is taken to be of uniform density then a negative electron is attracted towards the center with a force proportional to its distance from the center. The electrons of course repel each other. The electrons will distribute themselves uniformly throughout the sphere so as to neutralize it as completely as possible and can vibrate about their positions of equilibrium. According to Sir J. Larmor, atoms consist of a number of positive and negative electrons describing orbits about each other. There may be rings of electrons revolving round concentric rings. On this view an atom is a sort of small gaseous nebula without any sort of solid foundation.

A third theory recently adopted by Rutherford regards the atom as containing a nucleus of positive electricity with negative electrons outside it; probably describing orbits around it. On this view the atom is a sort of minute solar system. The positive nucleus will always require the same number of negative electrons to keep it neutral so that it provides a definite foundation fixing the identity of the atom. The same may be said of the sphere in Sir J. J. Thomson's theory.

I shall now proceed to very briefly review some of the evidence as to the nature of atoms that can be derived from different branches of physics and to consider how far the theories mentioned are consistent with it.

The most important property of atoms is their extraordinary stability in presence of each other. For example, the atoms in a compound molecule are very intimately associated and yet they preserve their identity even at the highest temperatures. The molecules in a gas are continually colliding violently with other molecules, yet the atoms are not destroyed. Negative electrons can be knocked out of atoms by the impact of rapidly moving particles such as the cathode rays and α rays, yet the atoms retain their identity and after regaining negative electrons are unaffected. Facts like these appear to be decisive against Sir J. Larmor's theory. On this theory we should expect

all mixtures of different substances to rapidly change into the same substance. There is in fact nothing in Sir J. Larmor's theory to account for the stability of atoms which according to any such theory would be broken up by collisions and could not preserve their identity in compound molecules. This theory fails to explain why free positive electrons can not be obtained while negative electrons are easily isolated. On the other two theories the stability of the atoms can be ascribed to the stability of the positive sphere or nucleus. When negative electrons are knocked out of the atom the excess of positive charge can only be neutralized by an equal number being replaced, which restores the atom to its original condition. Important evidence as to the nature of atoms is provided by the properties of gases interpreted according to the kinetic theory. The viscosity, rate of diffusion and other properties of gases seem to be best explained if the molecules are regarded as having a definite volume of radius about 10^{-8} cm. This is usually termed the radius of molecular action and two molecules which are separated by a distance greater than about 10^{-8} cm. can be regarded as having no appreciable action on each other. Similar conclusions can be derived from the theory of surface tension and many other phenomena. The energy necessary to remove a negative electron from an atom, for example, indicates that the positive and negative charges are about 10^{-8} cm. apart in the atom.

The most important evidence from the kinetic theory is derived from the ratio of the specific heat at constant pressure to that at constant volume. This ratio γ is equal, according to the theory, to $1 + 2/n$ where n is the number of degrees of freedom per molecule. For helium, neon, argon, krypton, xenon, mercury vapor and other gases $\gamma = 1.66$, which requires that $n = 3$. This means that when such gases are heated all the energy goes into the three degrees of freedom of translational motion of the molecules, so that the molecules acquire no energy of rotation or vibration. To explain this it appears necessary to suppose that the molecules behave like rigid smooth spheres. Such gases are therefore believed to be monatomic, each atom behaving like a smooth sphere. These gases, however, give spectra containing many lines so that it is certain that their atoms contain electrons which can vibrate. It is necessary to suppose that collisions between these atoms do not set their electrons in vibration, which seems to require the electrons to be protected in some way. This seems to be strongly in favor of

Sir J. J. Thomson's theory and against the other two theories, for if the electrons were describing orbits outside it is hard to see how they could escape violent disturbance during a collision.

Gases like nitrogen, hydrogen and carbonmonoxide have $\gamma = 1.4$, which gives $n = 5$. This means that their molecules behave like smooth rigid solids of revolution. These gases are diatomic, so that it appears that the two atoms in the molecule are firmly fixed together. This can be explained on Sir J. J. Thomson's theory by supposing that the two positive spheres stick together and it can not be explained on the other two theories.

The theory of the constitution of chemical compounds seems to require the atoms in compound molecules to be firmly fixed together in definite relative positions. The numerous cases of stereoisomerism and optically active isomers seem conclusive as to this. Similar conclusions follow from the properties of crystals which can be explained in many cases by supposing the atoms combined in a definite way throughout the crystal so that the whole crystal is, so to speak, one large molecule.¹ The rigidity of many crystals requires the atoms to be firmly fixed together.

On Sir J. J. Thomson's theory two atoms can stick together if one or more electrons are transferred from one to the other. In this case they would attract each other with great force and we may suppose the positive spheres to be flattened up against each other by the pressure so as to form a rigid combination.

Sir J. Larmor's theory and Rutherford's planetary theory are difficult to reconcile with the idea that atoms become firmly fixed together in compounds and rigid solids. On such theories we should expect to have nothing but gases and liquids and only very simple compounds.

Another important property of solids is their impenetrability by gases. This seems to require the atoms to occupy nearly the whole volume. The compressibility of solids is not great and does not diminish much at low temperatures. If atoms were made up merely of electrons of very minute volume we should expect solids at very low temperatures to contract to a very small volume or at any rate to become easily compressible. This again is in favor of atoms with a definite volume of radius about 10^{-8} cm. as on Sir J. J. Thomson's theory. This argument is taken from the Faraday lecture for 1911 by Professor Richards, who puts

¹ See A. E. H. Tutton, "Crystallography," London, 1911.

forward many good reasons for the view that atoms have a definite volume and are compressible.

The number of negative electrons in atoms can be deduced from observations on the scattering of the β rays of radium or of Röntgen rays and in other ways, as Sir J. J. Thomson has shown. The results obtained indicate that the number is a small constant multiple of the atomic weight.

The scattering of α rays led Rutherford to adopt the idea of a positive nucleus, since some α rays are turned through a larger angle than can be explained by the electric forces due to a charge equal to that on one electron. It may be, however, that other forces besides ordinary electric force act on α rays when moving through matter. The α rays are helium atoms which have a radius about 10^{-8} cm., so that they probably only get through by displacing the atoms of the matter. If we suppose the positive sphere of one atom can not penetrate into that of another then the scattering of α rays by matter can probably be explained on Sir J. J. Thomson's theory.

The most interesting application of Sir J. J. Thomson's theory is the explanation which it affords of the relation between the atoms in series of similar elements like fluorine, chlorine, bromine, iodine. Sir J. J. Thomson supposes that the negative electrons in the sphere are arranged in concentric spherical layers and that each element in a series of similar elements is derived from the one before it by the addition of one more layer. The writer² has worked out this idea and shown that it is in approximate agreement with the atomic weights and that the number of electrons per atom can be deduced approximately from the atomic weights. The result obtained was that the number of electrons is about eight times the atomic weight.

Probably the most promising of the many ways of obtaining evidence as to the structure of atoms is by the study of the spectra of the light which they give out when set vibrating by different disturbing agencies. Most spectra, however, are so complicated that very little progress has yet been made. The fact that spectra contain lines of definite wave length suggests that the electrons in the atom vibrate about positions of equilibrium or else are moving in magnetic fields of constant strength. This seems to be a strong argument against theories of the planetary type, for on such theories the period of vibration is not fixed, but depends on the radius of the orbit.

Any theory which explains spectra ought also to explain the Zeemann effect.

² *Phil. Mag.*, June, 1911.

An important question is whether all the lines in the spectrum of an element can be emitted by each atom or whether the different lines are emitted by different systems. The second view now seems the more probable. On this view the different lines do not correspond to the different possible modes of vibration of each atom, but each line is due to the vibration of a different system. Of course a particular system may give more than one line in some cases. Thus we might suppose a regular series of n lines to be due to the vibrations of molecules with one, two, three up to n atoms in the molecule. Other series for the same element might be due to molecules which had each lost say m electrons with up to n atoms per molecule. On this view the frequency of vibration would be a function of two integers n and m . The different series in the spectra of the alkalis can be represented approximately as functions of two integers, as is well known.

The only theories of series spectra which have been developed to any extent are due to Ritz ("Gesammelte Werke W. Ritz," Paris, 1911). In his earlier papers he supposed the lines in each series to be due to different modes of vibration of an elastic membrane having special properties. Later he abandoned this view and supposed each line due to a different system.

Ritz's atomic vibrator consists of an electron vibrating in the magnetic field of a bar magnet at a point along its axis. The electron is supposed to stay close to a particular point on the axis and to vibrate in the plane perpendicular to the axis. The distance from the electron to the nearest pole is taken to vary by equal increments and the distance between the two poles also is supposed to vary by equal increments in going from one atom to another. This makes the frequency a function of two integers and the function found agrees approximately with the observed frequencies. However, to obtain exact agreement Ritz had to suppose the increments to be not always exactly equal. Ritz supposed the bar magnet to be made up of a row of nearly equal elementary magnets. In any atom some of the elementary magnets are in the row and the rest may be supposed arranged so as to neutralize each other.

This idea of elementary magnets receives some support from recent work on the magnetic properties of bodies by Weiss and others. The elementary magnets of course may consist of electrons moving round orbits.

It now seems probable that the formulae proposed for the representation of series spectra are not quite exact and are consequently to be regarded as merely empirical and so without much real physical significance. Almost any function of integers containing four or five arbitrary constants will represent with accuracy a series of values which vary in a regular way.

Ritz's theory seems to the writer to be very artificial and altogether improbable.

In conclusion we may say that while we are still far from arriving at a complete theory of atomic structure yet some progress has been made in that direction. It is easy to get a theory which will explain any particular set of facts, but the same theory will not explain all the different sets of facts.

As to the bearing of radioactivity on this question reference may be made to a paper by J. W. Nicholson in the *Philosophical Magazine* for December, 1911. The serious objections to planetary theories pointed out above apply to his suggestions. *The Work of the Bureau of Standards*: Dr. S. W. STRATTON, Director.

For purposes of administration, the Bureau of Standards is for the present divided into seven divisions. The first four are based somewhat upon the usual divisions of the subject of physics, the work consisting primarily in the solution of problems relating to standards, of measurement, precision measuring instruments, methods of measurement and the determination of constants. They also investigate the properties of materials when the determination of such properties involves the services and equipment of the physicist rather than those of the engineer. The fifth division includes the principal chemical work of the bureau. The sixth division, having to do principally with engineering tests and investigations not ordinarily included in the four physical divisions, is scarcely organized as yet, except in certain lines of testing. The seventh division, the newest and largest in the bureau, relates to the investigation and testing of engineering, structural and miscellaneous materials. The various divisions are subdivided into sections, based upon the natural classification of their work, and sometimes upon the lines along which the experts specialize. The bureau is perhaps unique in bringing together the physicist, the chemist and the engineering investigator into closer relationship than at any other scientific institution in the country. Every effort is made to promote cooperation, even at the expense of organization if need be.

The act establishing the Bureau of Standards authorizes it to take up, in addition to the usual problems in connection with the physical units and standards, the determination of physical constants and the properties of materials, that is to say, Congress in enacting this law recognized the necessity for standard values of constants and standards of quality as well as standards of measurement. Uniform and accurate values of physical constants are as essential in scientific investigation, engineering work or commerce and trade as are uniform and reliable standards of length or mass. Similarly, well determined and defined properties of materials are equally important in the design of structures, the operation of machinery and the various mechanical uses of materials. A knowledge of materials is necessary for their most efficient and economical use. The problems awaiting solution in connection with the properties of materials are almost infinite in number; hence, the bureau's work in this direction will be confined for some time to come to those investigations which are necessary for the production of standard values or authoritative data.

Attention should be directed to certain phases of the bureau's work, which are of great importance and which might be called the "by-products" of the bureau. These are, furnishing to the public information acquired by the bureau in the exercise of its functions; the giving of information to the other bureaus and institutions of the government concerning physical, chemical and engineering questions involved in their work, and the giving of information to state and municipal governments and especially to public service commissions, which are becoming a very important factor in state legislation. The experts of the bureau are consulted in regard to scientific principles involved in the enactment of legislation and the establishment of regulations. At this time the bureau has in press several publications intended primarily for the assistance of state and municipal governments and public service commissions. Another important "by-product" is the influence that the bureau is exerting upon the development of scientific methods and the establishment of research laboratories in connection with our industries. The efforts of the bureau in connection with the work of these laboratories and in undertaking its own technical researches will always be directed toward basing such investigations on sound scientific principles, and to assist those industries in a wider and more efficient use of the scientific discoveries. Finally, through the efforts

and influence of the bureau it has been largely instrumental in bringing into closer cooperation the different national bureaus with a view to international agreement as to the fundamental questions involved in matters pertaining to standards.

The following seventy research papers were presented at the sessions of Wednesday, Friday and Saturday, in charge of the officers of the American Physical Society. Most of them will be published, either in abstract or in full, in the *Physical Review*.

"An Important Practical Problem in Gyrostatic Action," W. S. Franklin, Lehigh University.

"A Relation between the Magnetic Hysteresis and the Tensile Strength of a Series of Iron-carbon Alloys," C. W. Waggoner, West Virginia University. (Read by title.)

"Relation between the Joule Effect and the Permeability in the Same Specimens of Steel," S. R. Williams, Oberlin College.

"A Magnetic Test as a Means of Determining Flaws and Mechanical Strains in Iron and Steel," Chas. W. Burrows, Bureau of Standards.

"The Electrical Resistance and the Polarization E.M.F. of a Mixture of Clay, Feldspar and Quartz," A. A. Somerville and O. E. Buckley, Cornell University.

"A Kinetic Theory of Gravitation; Some Explanatory Remarks on my Paper of Last Year," Charles F. Brush, Cleveland.

"Some Diffraction Photographs," Mason E. Hufford, Indiana University.

"Demonstration of Linear and Surface Thermopiles of Bismuth and Silver," W. W. Coblenz, Bureau of Standards.

"The Vertical Temperature Gradient of the Atmosphere," Wm. R. Blair, Mount Weather Observatory, Bluemont, Va.

"A Modified View of Electronic Conduction," Walter P. White, Geophysical Laboratory.

"The Application of Statistical Principles to Photoelectric Effects and Some Allied Phenomena," O. W. Richardson, Princeton University. (By title.)

"The Velocity-distribution Curves of Electrons Liberated by Different Sources of Ultra-violet Light, and the Bearing of these Curves on the Planck-Einstein Theory," R. A. Millikan, University of Chicago.

"A Study of Crystal Rectifiers," R. H. Goddard, Clark University.

"The Half-value of the Radioactive Deposit Col-

lected in the Open Air," F. A. Harvey, Syracuse University.

"Distribution of Current in Point-Plane Discharge," Robt. F. Earhart, Ohio State University.

"The Influence of Temperature on the Phenomena of Phosphorescence in Zinc Sulphide," H. E. Ives and M. Luckiesh.

"On the Free Vibrations of a Lecher System using a Lecher Oscillator, II.," F. C. Blake, Ohio State University. (Read by title.)

"The Thomson Effect in, and the Thermal Conductivity of Tungsten, Tantalum and Carbon at Glowing Temperatures," A. G. Worthing, National Electric Lamp Association, Cleveland.

"The Effect of the Electrical Discharge on Solids and Liquids Suspended in Air," W. W. Strong, University of Pittsburgh.

"A Quantitative Measure of Development in Scientific Observation," Otto Stuhlmann, Jr., Stevens Institute of Technology, Hoboken, N. J.

"Elastic Hysteresis in Metal Bars," A. G. Webster and T. L. Porter, Clark University.

"The Spectra of Iron and Titanium at Moderate Pressure," H. G. Gale, Chicago University.

"The Spark Spectra of the Alkaline Earths in the Schumann Region," Theodore Lyman, Jefferson Physical Laboratory, Harvard University.

"Demonstration of the Resonance Spectrum of Iodine in Vacuo and in Helium," R. W. Wood, Johns Hopkins University.

"A Convenient Device for Obtaining a Steady High Potential for Electrometer Work," A. H. Forman, Cornell University. Introduced by J. S. Shearer.

"The Form of CO₂, SO₂, and NH₃ Crystals," H. E. Behnken. (Introduced by J. S. Shearer.)

"A New Method of Photographing Sound Waves," A. L. Foley and W. H. Souder, Indiana University.

"Another Instrument for Photographing Sound," A. G. Webster, Clark University.

"The Influence of the Natural Periods of Concentrating Horn and Diaphragm upon Sound Wave Records, and the Quantitative Analyses of Tones from Several Musical Instruments," D. C. Miller, Case School of Applied Sciences.

"Slit Width Corrections in the Photometry of Black Body Spectra," E. P. Hyde, National Electric Lamp Association, Cleveland.

"The Effect of Temperature on the Absorbed Charge in Electric Condensers," Anthony Zeleny, University of Minnesota.

"The Influence of Neighboring Conductors upon

a Klemencic Receiver of Electric Waves," A. D. Cole, Ohio State University.

"The Absorption of Beta Rays by Gases," A. F. Kovarik, University of Minnesota. (Read by title.)

"The Absorption of Gamma Rays of Radium by Air at Different Pressures," H. A. Erikson, University of Minnesota.

"Poynting's Tangential Method for showing the Existence of Radiation Pressure an Assumption unwarranted by Experiment," R. A. Wetzel, College of the City of New York.

THE PROCEEDINGS AT THE CENTENARY OF THE ACADEMY OF NATURAL SCIENCES OF PHILADELPHIA

AN adequate celebration of the one hundredth anniversary of the academy was urged by the academy secretary early in February, 1911, and was entrusted to a general committee of forty-three. The celebration thus provided for extended over three days: the 19th, 20th and 21st of March. It began on the 19th because that was the stated meeting night of the academy, the 21st being the actual date of the anniversary. The lecture hall on the evening of the 19th was well filled with people, the front seats being occupied by delegates, who, to the number of one hundred and forty-seven, had been appointed by corresponding societies at home and abroad.

The president of the academy, the Honorable Samuel Gibson Dixon, M.D., LL.D., took the chair promptly at 8 P.M., and introduced the Honorable Rudolph Blankenburg, mayor of Philadelphia, who, in a few well-chosen words, cordially welcomed the visiting scientists to the city. The recording secretary, Edward J. Nolan, M.D., then requested the delegates, as the names of the societies they represented were called by the corresponding secretary, J. Percy Moore, Ph.D., to arise, bow, and hand their letters of credential and congratulation to the president without reading. As the exercises of the evening were likely to be lengthy, he asked that any remarks considered desirable should be very brief. Thus warned, as a matter of fact, no one spoke, and as much the greater number of the two hundred and eighty-six letters received from all parts of the world

had been already delivered by mail, this otherwise tedious part of the program was not unduly prolonged.

The president then delivered his historical address as follows:

ADDRESS OF THE PRESIDENT

Fellow Members and Guests: This is one of the occasions which stimulate reflection. To-day we must all feel a regret that we can not inherit the learning of those who have gone before us. So keen an appreciation do I possess of the unselfish devotion of my predecessors to science and to this institution, and so impressed am I at our monthly meetings in our reading room by the regard of their portraits hanging on our walls, that I am impelled to call upon them in spirit to join me in extending to our guests the heartiest of welcome and to say that we, the present workers, fully appreciate how much credit is due them for our present success.

To-day this City of Brotherly Love, with the mother commonwealth, Pennsylvania, in common with the great union of states, is in peace with all the nations of the globe. This blessed condition did not prevail on the day when our forefathers assembled one hundred years ago, to organize an institution for the study and advancement of the natural sciences. During the last days of the year 1811, the dispute between the United States and Great Britain and the doubt as to the attitude of France seemed to indicate that the national honor was hurt and that another contest with a European power was at hand. The commerce of the country had suffered. The Committee on Foreign Relations recited the wrongs that the United States had suffered from Great Britain, and declared it to be the sacred duty of Congress to call forth the patriotism and resources of the country. Extensive military measures were

recommended. The Pennsylvania Legislature passed acts for enlarging the regiment of artillery and for the organization of the cavalry of the city of Philadelphia. Although war was not declared until June, 1812, in anticipation of the necessities of the situation Congress approved a loan of eleven million dollars, of which one million six hundred and forty-five thousand dollars was raised in Philadelphia.

Large meetings of people took place all over the city to consider the needs of commercial interests and to pass resolutions for the equipment of privateers and for building up the defenses of the city.

The legislature relieved the tension of its patriotic resolutions by requesting a special committee to examine a machine made by Charles Redhefer, who claimed that it possessed the power of self motion, and naively stated that "if the machine be found to be imperfect the public interest will be promoted by exposing its fallacy."

In the midst of these excitements the youth of the city naturally sought the taverns and oyster cellars as meeting places, as indeed there was little in the way of diversion provided for the people of that period. The theater was seldom opened, and the feeling against it was so strong that a petition was presented to the legislature requesting it to abolish forever the exhibition of "Theatricals." Peale's Museum enjoyed great popularity, and here the *lusus natara* was in steady demand. The calf with five legs vied for public favor with the child without ears.

Notwithstanding the preparations for war which were draining the resources of all men, the fathers of this institution had such faith in the future of the United States of America that they did not hesitate, even with the din of martial demonstrations in their ears and the consciousness of an awful, impending struggle with

gigantic powers in their minds, to proceed quietly, methodically and unperturbed to found an association for pure learning which has now become one of the foremost among the scientific institutions of the world.

The vibrations, whose echoes still resound in this Hall of Science, though the voices that started them can no longer be heard, are too numerous to be mentioned on this occasion, when there is so much that is new to be brought out within the short time allotted for our assemblage for the last time in the academy's first century.

This institution was born of the enthusiasm of earnest lovers of science. They had before them a single purpose, the unveiling of the laws of nature and the engraving of them on the tablets of the society that they might be studied by men of all nations. To accomplish this great end as the society grew they realized the necessity of exploration, of collections, of laboratories, of a library and of reciprocity with bodies having similar aims.

In the beginning of the nineteenth century a few young men in this city spent their spare time in studying natural history. They soon learned it was to their mutual interest to meet to compare notes. In the year 1812 John Speakman and Jacob Gilliams agreed that it would be well to hold regular meetings; accordingly, they, with Drs. Gerard Troost, Jr., Nicholas S. Parmentier, Camillus Macmahon Mann and John Shinn, Jr., met at the home of one of their members on the northwest corner of Market and 2d Streets, on January 25, 1812. The minutes of this meeting set forth that their meetings would be for the rational disposition of their leisure moments. Their next meeting was held at a public house on Market Street near Franklin Place on the 21st day of March, 1812, at which time Dr. Samuel Jackson,

of the University of Pennsylvania, suggested the title of The Academy of Natural Sciences. The collection of the society at this time was represented by a few common insects, a few corals and shells, a dried toad fish and a stuffed monkey.

Thus established, the academy, with its constantly increasing resources, has been for one hundred years free for the use of all students of natural history.

The masters of science have come from all parts of the world to consult the great zoological, botanical, geological and ethnological collections which the accumulated labors of our members, during a century of activity, have brought together in our museum.

Writers and students of all grades have come to consult the wonderful natural-history library which the liberality of our members and the world-wide exchange of our own publications have enabled us to gather on our shelves.

Pupils from our schools have come under the guidance of their teachers to study and profit by the exhibits displayed in our public museum halls, while our specialists have delivered courses of popular lectures on the natural sciences under the auspices of the academy and the Ludwick Institute.

In every way within its power the academy has stood for a century as the advocate of the study of the natural sciences, advanced or elementary, pure or applied.

And this, our one hundredth anniversary, is a particularly happy birthday because our precious natural history library of volumes unexcelled in America, and our priceless collections of mammals, birds, reptiles, fishes, shells, insects, plants, ethnological and geological specimens unsurpassed in several of the departments and all of them rich in the type specimens of the early naturalists of America, having been for almost one hundred years exposed

to the danger of damage or destruction from fire, are now, through the intelligent liberality of the commonwealth of Pennsylvania, placed in a thoroughly fire-proof building.

The society has, however, never received state or city financial aid for maintenance, but has depended entirely upon the liberality of intelligent people, mainly of Philadelphia, to contribute the necessary funds to purchase land for our buildings, to publish the results of the scientific researches of our members, to fit out expeditions and of late years to pay meager salaries to the members of our scientific staff.

While we have thus built up fine study collections, it has been impossible to develop the popular exhibits that other sister institutions, rich in state and municipal appropriations, have been enabled to instal.

We have, however, kept our collections systematically arranged and have, during the last decade, had the satisfaction of seeing all our historical types and the numerous recent accessions placed in metal cases, impervious to light, dust or moth; which will insure them the longest possible life.

Our honorary corresponding membership now numbers about two hundred, composed of the greatest scientists of the period.

Biographical sketches of our officers and scientific workers who carried us through the last one hundred years are printed in our publications, and as we have so little time before us they can only be casually alluded to in this brief résumé of the academy's history. We are, however, proud of the escutcheon upon which the history of their lives is engraved.

Members of this academy have taken a very prominent part in explorations. Thomas Say was a member of the "Long Expedition" to the Rocky Mountains in 1819 and 1820 and was one of the first scientific men to become personally ac-

quainted with the vast natural history resources of the great west.

Nuttall and Townsend, thirty years after the Lewis and Clark expedition, crossed the continent to the mouth of the Columbia River, and then extended their explorations to the Hawaiian Islands, returning around the Horn. They brought home rarities of animal and plant life, many of which were unknown to science. These collections were placed in the academy's museum, then the chief repository for natural-history specimens in America and here they are still preserved.

When the United States government was organizing the famous Wilkes expedition of 1838, the academy was requested to nominate its scientific staff and two of its members eventually accompanied the party.

In the year 1850 one of our members, Edward Harris, financed and accompanied the great Audubon expedition up the Missouri River. Through his modesty, we were prevented at the time from making known the important part that he took in this expedition. Other members made possible the exploration of DuChaillu in equatorial Africa.

We provided Dr. Kane with his outfit for systematic collecting in 1853 when he made his Arctic expedition. To-day we have in our collection his famous Esquimau dog, "Toodla," as well as numerous other specimens obtained by him. Specially interesting is the gigantic stuffed polar bear which stands in interesting contrast to the modern mounted specimen brought here by the Peary "relief expedition."

The Hayes expedition to the far north a few years later was also aided and endorsed by the academy.

Rear Admiral Peary, discouraged by his futile attempts to interest other institutions and governments in his proposed voyage of exploration to the north, came to us

with his proposition. He was generously received and a committee was appointed to arrange the expedition, which sailed on June 6, 1891, from Brooklyn, under the auspices of the academy, to explore the Arctic regions. On January 26, 1892, we authorized a relief expedition under the command of Professor Heilprin. On September 24, 1892, we officially met the relief expedition sailing up the Delaware River on the now historic vessel *Kite*.

Dr. Hayden, a member of the academy, when conducting the United States Geological Survey in the west, made up his scientific parties largely from our membership. The setting apart of the great national Yellowstone Park resulted from his numerous explorations. Every three years this institution bestows upon a distinguished geologist a gold medal called the Hayden Medal, an award which was founded by Dr. Hayden's widow.

The Pennsylvania Geological Surveys were also conducted by our academy members, Rogers and Lesley.

Our famous colleagues, Leidy and Cope, were the pioneers in describing the extinct animals from the wonderful deposits of the western states.

I may mention among the more recent expeditions the one under Professor Heilprin to Yucatan and Mexico in 1890, the Harrison and Hiller expedition to Sumatra, the numerous explorations of Mr. Clarence B. Moore, the Rhoads expeditions to British Columbia, Colorado and Ecuador, the Donaldson-Smith expedition to Somali-Land and Lake Rudolph, and the Bond expedition to Venezuela, from all of which we have received rich returns.

The academy publications had early a world-wide reputation. For many years they furnished the only adequate means through which American scientists reached the naturalists of the world. Contributions

for publication came from all parts of America. To-day our *Proceedings* and *Journal* are exchanged with all the nations of the civilized world. It may be interesting to state here the fact that when the famous Pacific railroad surveys were made the United States government published descriptions of all the new specimens it obtained in the academy *Proceedings*.

Passing rapidly over the more important departments of our museum, we find among mammals a number of the specimens obtained by Townsend in the far west, made known to science in our *Journal* by our correspondents Audubon and Bachman; the Harrison Allen collection of bats, the Rhoads collection of North American mammals and the splendid collection of anthropoid apes presented by Dr. Thomas Biddle.

Our collection of birds will ever stand as a memorial to two of our members, Thomas B. Wilson and John Cassin. To Dr. Wilson's liberality we owe the acquirement of the famous Rivoli collection, the Gould collection and many others. His entire gift, comprising some 25,000 specimens, was regarded in 1850 as the finest collection in the world. Cassin spent his life in the study of this vast collection and his researches published in our *Proceedings* made our academy famous as an ornithological center, while he himself stood preeminent among the ornithologists of America.

The part that the academy played in the development of ornithology in America may be appreciated by the mere mention of those who worked within its walls or published the results of their researches in the *Proceedings*—Nuttall, Bonaparte, Townsend, Gambel, Heermann, Harris and Woodhouse, among our members, and Baird, Lawrence, Henry and Coues, among our correspondents.

In our vast series of reptiles, we find the material collected and studied by Hallowell,

Cope and Brown—names inseparable from the history of herpetology in America.

In the study of fishes at the academy the names of Bonaparte and Cope, already mentioned in other connections, stand forth prominently and their collections are still carefully preserved. Charles Lesueur, one of our earliest members, also attained fame as an ichthyologist, while of late years several of those who studied at the academy have become famous in the service of the United States Fish Commission—notably John Adam Ryder.

As regards mollusks, the academy has from its foundation taken a prominent part and has accumulated a collection probably second to none. A series of investigators, eminent in their special field, have made the society one of the world centers in the study of mollusks.

Almost a century ago Thomas Say blazed the trail for conchologists, while Dr. Isaac Lea and T. A. Conrad were his successors in the academy in this department. Lea's work, largely published by the academy, is the basis of all later systematic study of fresh-water mussels, while to Conrad we owe the foundation of American tertiary geology and paleontology, his work in this line overshadowing that on the living mollusca. Gabb was another famous worker in the same field, while to Geo. W. Tryon we owe the conception of the "Manual of Conchology," begun by him in 1878 and continued by the academy after his death in 1888. Very few works have led to so many reforms in classification or have such a broad influence as this. Dr. Joseph Leidy, who may be termed the Cuvier of America, should be mentioned in this connection because of his work forming the first volume of Binney's "Terrestrial Mollusks of the United States," published in 1851. This was the first American work on the morphology of the soft parts of our mollusks.

Thomas Say, already referred to as a pioneer conchologist, is also known as the father of American entomology. Owing to his energy, the academy's collection in this department was begun—a collection which by steady growth has reached a total of a million specimens and has become of world-wide renown. The long list of entomologists who have contributed to its development contains most of those whose activities constitute the earlier history of entomology in America.

Titian R. Peale, Wilson, LeConte, Horn, McCook, Cresson, Martindale and others have made our entomological department one of the first importance. The Cresson collection of hymenoptera has made the academy the greatest in America in this particular branch. The Bassett collection of galls and gall insects is the most comprehensive ever brought together.

In paleontology the names of Leidy and Cope are preeminent. The "Extinct Fauna of Dakota and Nebraska," published by Dr. Leidy in our *Journal*, is a classic. Students of paleontology still come to consult the types of his descriptions, most of which are preserved in our collection.

Professor Cope's part in the development of American paleontology is too well known to require detailed mention and was carried on side by side with his studies of reptiles and fishes, in which his reputation was equally great. On his death-bed he placed the finishing touches to his report on the pleistocene remains discovered at Port Kennedy, Pennsylvania, a paper which attracted the attention of the paleontological world and which appeared in the *Journal* of the academy soon after his death.

In botanical research the academy has always held an important place and its herbarium, now numbering some 900,000

specimens, contains the types of such pioneers as Nuttall, Pursh, Muhlenberg and de Schweinitz besides comprehensive collections from all parts of the globe. Among those whose researches have been carried on at the academy may be mentioned, in addition to the above, Durand, Charles E. Smith, Meehan and Redfield.

In anthropology the work of Morton and later of Harrison Allen is famous. The splendid collection of human crania brought together by the former is historic. Archeological and ethnological collections comprise the material gathered by S. S. Haldeman in North America and the land of the Aztecs, Mayas and Incas.

We have also the Wm. S. Vaux collection, rich in specimens of the neolithic age of Europe, the Robert H. Lamborn collection and the Clarence B. Moore collection.

This latter represents the results of more than twenty years' exploration in the southern United States and consists of thousands of specimens of the vanished art-industries of our southern aborigines now saved for all time in our museum and in the fine series of reports published in our *Journal*.

We have extensive mineral collections, foremost among which is the Wm. S. Vaux collection, famous for the beauty of its specimens and the completeness of the series.

There are the famous Febiger collection of diatoms and others, which lack of time forces me to pass over.

So, too, there are many former members of our academy who by their scientific attainments or their loyal and generous support have helped to build up the institution, while among our living members are men who are, by their work and devotion, fully as deserving of notice as those who have gone before.

Helmholtz, in 1862, said:

In fact men of science form, as it were, an organized army, laboring on behalf of the whole nation, and generally under its direction and at its expense, to augment the stock of such knowledge as may serve to promote industrial enterprise, to increase wealth, to adorn life, to improve political and social relations and to further the moral development of individual citizens. After the immediate practical results of their work we forbear to inquire; that we leave to the uninstructed. We are convinced that whatever contributes to the knowledge of the forces of nature or the powers of the human mind is worth cherishing, and may, in its own due time, bear practical fruits, very often where we should least have expected it.

It has been truly said that the distinctive feature of pure science is "that it is not remunerative; the practical rewards and returns are not the immediate ends in view." The work of Tyndall and Pasteur, however, on fermentation, pursued in the beginning purely because of its abstract scientific interest, later came to have enormous economic importance and led to the scientific investigations that have within recent years become of incalculable value to mankind.

The knowledge gathered by the abstract naturalist and the tabulation of scientific data concerning all forms of animal and vegetable life have a very close and direct relation to public health and preventive medicine. A long list of diseases might be compiled in which some of the insects are directly responsible for the transmission of the bacterium or parasite life causing disease. It is now a matter of almost universal knowledge that malarial fever is transmitted from man to man by means of the *Anopheles* mosquito, that the yellow fever virus can only be transmitted by the *Stegomyia calopus*, that the bubonic plague may be transmitted from man to man or from rat to man by means of the rat flea (*Pulex cheopis*), that the *Trypanosoma gambiense* of African sleeping sickness can be transmitted only by means of the tsetse-

fly, that the organism causing human filariasis is transmitted by the *Culex fatigans* and certain of the *Anopheles*, and evidence is gradually accumulating that the germ of leprosy is transmitted by the bed-bug (*Cimex lectularius*). A knowledge of the natural history of these insects is absolutely essential for the scientific study of the diseases with which they are so closely associated, and public health work has only been effective in eradicating these diseases in proportion to the efforts of the sanitarian directed toward their destruction or toward protecting individuals from them. The entomologist, the zoologist and the bacteriologist are each required to contribute their share in the research that means so much to public health and to mankind. If much has already been accomplished, still greater are the fields open for scientific investigation.

With the lower forms of animal life parasitic to man and known to cause disease, the connecting link, the intermediate host, the full life history is missing in many instances where it would seem that the most fertile field for the scientist has not yet been invaded. A very large field lies open for those who will undertake a careful study of the relation between the vermes and the human being. Much indeed has been learned about parasites inhabiting the intestinal canal, but the parasitologist has not yet concluded the final analysis of the life history of many of these parasites.

The work of the academy has been so distinctly pure science that the lay public have not until recently appreciated the great practical relationship it has to health and economics. The description of the various species, their life history, their geographical range, have enabled those working in applied sciences to conduct the already successful war against the enemies

to man, to the lower animals and to plant life.

Economic entomology, based upon abstract work, shows an annual money loss occasioned by insects as follows:

Cereals	\$300,000,000
Hay and forage	66,500,000
Cotton	85,000,000
Tobacco	10,000,000
Truck crops	150,000,000
Sugars	9,500,000
Fruits	30,000,000
Farm forests	11,000,000
Miscellaneous crops	10,000,000
Animal products	300,000,000
Natural forests and forest products ..	100,000,000
Products in storage	200,000,000
Total	\$1,272,000,000

Let it be remembered that in 1793 half the population of Philadelphia either died from yellow fever or voluntarily exiled themselves to escape from the scourge, that all the southern tier of states were kept in a state of constant terror every summer for fear of its invasion, causing a loss of millions to the commerce of the country, and then recall the fact that through entomological and medical cooperation this disease was practically eliminated from Cuba, its breeding place for ages, and that in 1905 a violent epidemic of the same plague was actually checked in New Orleans by the practical application of the knowledge gleaned by the medical department of our army in Cuba.

That mysterious blight to human life and energy, known as malaria, to which, as much as to the fire and sword of northern barbarians Greece and Rome owed their downfall, has been traced to its entomological source so that these two devastating diseases have ceased to be a menace to civilized communities, allowing that great work, the construction of the Panama Canal, heretofore impossible owing to their prevalence, to go on uninterruptedly under

conditions of unparalleled health, that the sacrifice of 5,000 American troops during the Spanish-American war was finally found to have been due to the transmission of bacillus typhosus by the common house fly, and that this knowledge was so judiciously applied by our army surgeons that a recent considerable mobilization of our soldiers was entirely exempt from that disease, and some faint conception will be reached of the immense debt that humanity owes to the patient workers in the field of pure science.

President George Washington, in his first message to Congress, said:

Nor am I less persuaded that you will agree with me in the opinion that there is nothing more deserving your patronage than the promotion of science and laboratories, knowing in every country it is the surest basis of public happiness, one in which the measures of the government receive their impressions so immediately from the sense of the community as ours it is proportionately essential.

The mass of congratulatory letters with their autographs of our foreign co-workers received from the great institutions of the world relating to this our one hundredth birthday, can not be read, owing to a lack of time.

Before closing I have a pleasant duty to perform in behalf of the Building Committee. At the request of those entrusted with planning and erecting the building improvements, made possible by the commonwealth of Pennsylvania, as chairman of said committee, I hand over to the corporate body, under the title of The Academy of Natural Sciences of Philadelphia, this building completed for its use, which comprises fire-proof stacks for its library, a reading room, lecture hall and work room. In the rhythmic language of another, I reverently invoke the blessings of the God of Nature upon this temple of the natural sciences.

Great God of nature, let these halls
The hidden things of earth make plain;
Let knowledge trumpet forth her calls,
And wisdom speak, but not in vain.

Help us to read with humble mind,
Thy larger scriptures day by day—
True bread of life! O be thou kind,
If, erring, we should go astray.

For deep resounding unto deep,
Declares the wonders of thy plan;
Life struggling from its crystal sleep
Finds glorious goal at last in man.

The mysteries of the eternal laws,
Are but the shadows of thy might.
God, ruling all in final cause,
Enshrines the world in love and light!

—Harvey Watts

At the conclusion of the address it was explained that the routine of a stated meeting would then go on, in the belief that an illustration of the formula by means of which the academy had transacted its business for one hundred years would be of interest to those familiar with the results which made it worth while to hold the celebration on which they were entering.

At the call of the chair the recording secretary read the minutes of the last meeting, and also the minute of the first recording secretary, Dr. Camillus Macmahon Mann, an exiled Irishman, defining the date of the foundation of the society. The latter is as follows:

Year of the United States the 37th,
March 21st.

In committee agreed: The year of the Institution shall commence at the present natural evolution: the spring equinox, 21st of March and the year shall be named according to the era of the United States of America in the principle city of which we assemble.

Additions to the museum and library were announced.

The corresponding secretary reported on the letters received.

The report of the council, confined almost entirely to a consideration of the ar-

rangements for the celebration, was read.

The publication committee reported the titles of papers presented for publication since the last meeting, and also announced the details of works to be issued in connection with the centenary celebration: a quarto volume of memoirs, an index to the entire series of the *Proceedings* and *Journal*, and a detailed history of the academy by the recording secretary, which will make a volume of not less than 400 pages and to which the "Short History" contributed to the Philadelphia Founders' Week Memorial Volume may be regarded as a prodromus.

The chair reported the death that morning of Thomas Harrison Montgomery, Ph.D., the director of the zoological department of the University of Pennsylvania. The occurrence supplied a pathetic note to the proceedings, as Dr. Montgomery had been deeply interested in the arrangements for the celebration, had been assigned a place on the program of exercises, and had contributed the first paper, under the title "Human Spermatogenesis, Spermatocytes and Spermiogenesis" to the commemorative quarto volume.

At the place where "verbal communications" are usually called for, Dr. Nolan, under the title "Reminiscences," spoke of his connection with the academy as assistant librarian, librarian and recording secretary during the past fifty years, his earliest record of accessions to the library being dated February 4, 1862. He deeply regretted that he had not taken advantage of his acquaintanceship with certain contemporaries of the founders, who were still alive when he entered on the scene, such as George Ord, Jacob Peirce, Isaac Hays and Titian R. Peale to make notes of their recollections of the early days, but it could readily be believed that in his most sanguine moments he had never contemplated the possibility of being called on fifty years

later to record his regret before such an audience. He then spoke of the beginning of his work as an untrained assistant in the library and the unvarying kindness and consideration he had experienced from all the men met with at that time, but especially from his dear chief, J. Dickinson Sergeant, and his beloved future preceptor, Joseph Leidy.

It was an extraordinary epoch in the history of the academy, the beginning of its second half century, and the boy was associated with a stimulating group of men, including Leidy, Cope, Conrad, Tryon, Lea, Slack, Rand, Cassin, Heermann, Meigs, Gabb and Wilson, all men of marked individuality, some of whom have made permanent records as leaders of science in America.

Continuing, Dr. Nolan gave his impressions of some of his contemporaries of later date—Allen, Horn, Meehan, Ruschenberger, Ryder, McCook, Heilprin, Chapman, Isaac Jones Wistar and Arthur Erwin Brown—not by any means dealing in laudation exclusively, but indulging in kindly personalities in a belief that a more intimate tone than would be entirely desirable in a published record would not be disagreeable to his auditors, many of whom were familiar with the work of the men whom he was describing.

In the one hundred years of the academy's history four men had stood out prominently, with, of course, scores of associates, as dominant in its material and intellectual advancement. These were Thomas Say, Samuel George Morton, Joseph Leidy and the present chief executive. The work of Say, Morton and Leidy formed part of the history of the academy, and if impression were desired of the accomplishments of Samuel Gibson Dixon they had but to look around them.

Closing his remarks the secretary was

distressed to remember the names of the many dear friends whom, for lack of time, he was forced to leave in the undesirable class "and others."

Those whom he had known during the first years of association with the academy were nearly all dead. The old building, if it still existed, would be full of ghosts and even in the present halls, in the dusk of the winter days, dear shades encountered him in the alcoves and passageways and reminded him of the time when he too should be a tradition.

In conclusion he remarked:

But in the meantime it is with feelings of profound gratitude that I bear testimony to the kindly patience and sustaining encouragement of those who are still with me and who impart to the performance of the daily task much pleasure and little or no pain.

For obvious reasons I can not deal in personalities in the case of my living contemporaries, but I am at liberty to say that they are worthily taking the place of those who have labored so loyally for the advancement of the academy and who, we are not forbidden by the highest reason to hope, are now rejoicing in this splendid commemoration of their labors. Had they lived when men cherished the same truths under different formulæ their motto would have been *Ad maiorem Dei gloriam*.

May the men who come after us be as zealous and as disinterested in the development of truth as those whom I have been so ineffectually remembering to-night, so that when the second centenary is celebrated it also may be the subject of congratulation for a like gathering of kindly and appreciative friends.

Nominations for membership were read, the elections of those formerly proposed being deferred until the next meeting.

The rough minutes were then read for criticism and approval, as had been the custom for nearly one hundred years, the secretary explaining that he had complied with the directions of Dr. Mann and dated the record as having been made in the 137th Year of the United States. No cor-

rections being called for, they were adopted as read and the meeting adjourned until the following morning at 10 o'clock.

Wednesday morning, March 20. The day was sparkling, bright and genial and the hall was filled with delegates, members and visitors when Dr. Dixon dropped the gavel at 10 o'clock. The following papers, most of which were résumés of communications presented for publication in the commemorative volume, were then read:

Edwin G. Conklin, Ph.D.: "Experimental Studies on Nuclear and Cell Division."

Carlotta J. Maury, Ph.D.: "A Contribution to the Paleontology of Trinidad." The memoir will be illustrated with superb drawings of fossils from the accomplished pen of Professor Gilbert D. Harris, of Cornell University.

W. J. Holland, Ph.D.: "David Alter, the First Discoverer of Spectrum Analysis," with exhibition of the prism used by him.

John W. Harshberger, Ph.D.: "The Vegetation of the Banana Holes of Florida," well illustrated by lantern views.

Frederick W. True, M.S., LL.D.: "A New Species of *Delphinodon*."

Henry H. Donaldson, Sc.D., Ph.D.: "The History and Zoological Position of the Albino Rat."

Edward B. Meigs, M.D.: "The Ash of Smooth Muscle."

Marshall Avery Howe, Ph.D.: "Reef-building and Land-forming Seaweeds," illustrated by views and specimens.

At the conclusion of Dr. Howe's paper the audience adjourned to the new geological hall—the old library hall transformed—where a liberal luncheon was enjoyed.

The meeting reassembled at 2:30 P.M., when Benjamin Smith Lyman read a paper on "Natural History Morality." It was followed by the following:

Jacques Loeb, M.D., Ph.D.: "Experiments on Adaptation of Animals to Higher Temperatures."

Henry Skinner, M.D., Sc.D.: "Mimicry in Butterflies."

Spencer Trotter, M.D.: "The Faunal Divisions of Eastern North America in Relation to Vegetation."

T. Wayland Vaughan, Ph.D.: "Rate of Growth of Stony Corals," illustrated with lantern slides.

Henry A. Pilsbry, Sc.D.: "On the Tropical Element in the Molluscan Fauna of Florida."

The session closed with illustrations by means of a superb collection of lantern views, of methods of bird photography by William L. Baily.

In the evening a reception was tendered the delegates by Dr. Dixon, Mrs. Dixon and Miss Dixon in the Bellevue-Stratford Hotel. In common with everything else on the program it was brilliantly successful.

The weather Thursday morning was a violent and most undesirable change from that of the day before, a fall of snow being driven along by penetrating winds. It was a most gratifying evidence of the earnestness and interest of those attending the sessions that little falling off in the attendance was observable when Dr. Dixon called the meeting to order a few minutes after ten.

He opened the proceedings by referring to the death of Dr. Montgomery, who had been placed first on the program of that session. His place was taken by Edwin J. Houston, Ph.D., who made an interesting communication on "How the Natural Sciences can be made Attractive to the Young."

In continuation the following papers were read:

James A. G. Rehn: "The Orthopteran Inhabitants of the Sonoran Creosote Bush."

Merkel H. Jacobs, Ph.D.: "Physiological Characteristics of Species."

Henry F. Osborn, LL.D.: "Tetraplasy, or Law of the Four Inseparable Factors."

George Howard Parker, Sc.D.: "Sensory Appropriation as Illustrated by the Organs of Taste in Vertebrates."

John M. Macfarlane, Sc.D.: "The Relation of Protoplasm to its Environment."

William H. Dall, A.M., Sc.D.: "Mollusk Fauna of Northwest America."

The time having arrived for luncheon,

two papers were deferred to an afternoon session not provided for on the printed program.

On reassembling at 2 o'clock, Henry G. Bryant, LL.B., read a paper on "Governmental Agencies in the Advancement of Geographical Knowledge in the United States," and the scientific sessions concluded with a superbly illustrated and most interesting lecture by Witmer Stone, A.M., the ornithological curator of the academy, on the "Fauna and Flora of the New Jersey Pine Barrens." The communication was specially enjoyed by those from a distance as imparting in a most pleasing manner information regarding a region of quite unusual physiographical interest.

The rest of the afternoon was devoted to a demonstration of the resources of the museum and library, including a fine display of one hundred and thirty-two microscopes and an exhibition of a portion of the academy's superb collection of butterflies.

In the evening one hundred and sixty members and guests sat down to a banquet in the exquisitely decorated new geological hall, formerly occupied by the library. The occasion will long be remembered as a specially enjoyable one by those present.

Dr. Edwin G. Conklin, professor of biology in Princeton University and one of the vice-presidents of the academy, was an inimitable toastmaster and at his call appreciative speeches were made by the mayor, who sat on the right of the president; Mons. Jean de Pulligny, director of the commission of French engineers to the United States; Dr. Henry Fairfield Osborn, president of the American Museum of Natural History, New York; Dr. Dixon; Dr. Theodore N. Gill, of the Smithsonian Institution; Dr. William J. Holland, of the Carnegie Museum of Pittsburgh, and Dr. Nolan, all bearing testimony to the acad-

emy's influence as a source of inspiration and encouragement.

The celebration of the one hundredth anniversary of the institution which had produced such a marked effect on the progress of science in America finished with the singing of "Auld Lang Syne," the departing guests sympathizing with those who were unable to participate in the hearty and genial conclusion of a program which was unanimously declared to be a complete success.

THE MISUSE OF LANTERN ILLUSTRATIONS BY MUSEUM LECTURERS¹

THE illustrated lecture has long been a very prominent feature of the educational and scientific work of the public museums of this city. It has long been a feature of the meetings of clubs and societies of all kinds, not so much for instruction as for popular entertainment.

So general is the use of lantern illustrations at all sorts of gatherings, that it has become commonplace. It is necessary for the legion of lecturers who employ them to procure better, and yet better pictures, to make their performances attractive. We appear to be in the midst of a great rivalry as to who can make the finest pictorial display, and anybody, apparently, may occupy the platform.

At a recent meeting of ornithologists in Philadelphia, I sat for many hours watching a continuous performance of stereopticon lecturers. Some of them did their parts remarkably well, but the three-days meeting was manifestly, although unconsciously, a lantern-slide competition. During the intermissions, the audience, composed chiefly of professional ornithologists, talked almost entirely of the admirable pictures that had been shown, making animated comparisons of the success achieved by this or that photographer.

There have come among us hosts of skilful photographers or enthusiastic travelers, back

from hasty trips to Zuñi or East Africa, ready to exhibit the best of pictures, to any kind of an audience that they can get, and to talk more or less amusingly while doing so.

Many of these so-called lecturers are successful enough, and audiences are forthcoming anywhere from the Museum of Natural History to the Suburban Entertainment Club. Even Peary's colored cook is doing a rattling lecture business with his master's slides.

Good pictures are dangerous in the wrong hands. Imagine a dull and dreary talker, still talking in public if he were deprived of lantern slides.

The use of lantern slides should be on a safer basis. They should not only be reduced in number, but be partially replaced with something more intellectual.

There could be no objection to lantern pictures as an inexpensive form of entertainment, if it were understood to be chiefly for entertainment, but when a fine collection of pictures of the Grand Cañon, accompanied by the talk of a mere traveler, is announced as a lecture on geology, it is a sign that we are losing our powers of discrimination.

When some superb pictures of Indian habitations on the table-lands of the southwest are described by a mere photographer engaged in making money out of the lantern slides, shall the authorities of the great museum allow the performance to be advertised as a lecture on ethnology? The City Bureau of Free Lectures employs a legion of lantern slide lecturers on travel, some of whom doubtless have never visited the lands they describe in glowing terms. There are art lecturers in this city showing colored photographs of the great paintings of Europe, who have never seen the originals. I am not undertaking to condemn the work of the free lecture bureau. It doubtless affords thousands of people entertainment that is wholesome and not without instruction.

Some of the lecturers make a specialty of describing the wonders of the Art Museum, or the Aquarium, and I personally shouldn't care to lose that much free advertising for my own institution. No doubt the pictures

¹ Part of a paper read at a meeting of curators of the public museums of New York, December 19, 1911.

and talk about art send many persons to the Art Museum.

But shall the museums, holding, as they do, authoritative positions respecting art and science, disregard the fact that the amateur is among us with lantern pictures that may be better than ours? Is it not time to consider whether by continuing as we are doing, we may be cheapening the labors of the distinguished specialists who cheerfully do their part in our own lecture courses?

There are reasons for believing that the general public is pretty well satisfied with what it gets, and also that it is incapable of distinguishing between the noted authority and the mere amateur who has the same kind of pictures. Shall we continue to be satisfied with this kindergarten way of lecturing?

Shall we continue to supply sugar-coated science until even the more discriminating part of the public begins to think that the professional ornithologist is really no better than the enthusiastic amateur who can photograph birds just as well?

While there are many of our number who can lecture most acceptably using lantern illustrations, there are certainly some of us who habitually depend upon the effect of the pictures used. Lecturing with lantern illustrations has so nearly superseded the well-prepared, authoritative discourse, that the latter has become a rarity.

I am convinced that what we have come to call lecturing is not the real thing, that the effect of the present over-illustrated lecture upon the audience is not what it should be.

The presentation is to the eye rather than to the mind, and the audience accepts it with a passive, rather than an active mind. The audience is already lost to the lecturer; he does not see its face, and there is no response to him.

In the experience of most of us, many a slovenly lecture has been tolerated because of the excellence of its illustrations. We continue to endure the indifferent talk of the lecturer, because we seem to be getting our money's worth out of his pictures.

In such a case the lecturer, perhaps a man

of real scientific attainment, has actually degraded himself to the level of a showman. He may even be content with the applause bestowed only upon his achievements as a photographer.

But the audience, too, has degraded itself, by its intellectually languid acceptance. It will eventually tire of even the best of slides, and be satisfied with nothing less exciting than motion pictures.

The effect of the average lantern lecture can be readily judged by any one who cares to hear the remarks of the departing audience: "What splendid photographs," "How beautifully colored." We have all repeatedly heard just these words. The talk is of the *show*, and the self-satisfied showman on the platform has merely cracked the whip and given the signals to the real performer—the stereopticon man.

Let us contrast such a performance in the darkened hall, before an audience of sight-seers awaiting the next flash of the lantern, with that of a lecturer addressing the mind of his audience. Imagine Mr. Roosevelt or Beecher or Ingersoll receiving such applause as they have received if they had stood in the dark explaining pictures that might have told their own story. Have not some of our lecturers practically arrived at the point where the automatic lantern, carrying labeled slides, could do the trick as well?

But assuming that we must use pictures, what shall we say of the well-informed lecturer who thoughtlessly turns his back to the audience, and addresses the changing panorama on the screen, so that his weak voice can be heard only by those who sit in the front rows?

What shall we say of the lecturer, who, depending upon his pictures, has not prepared himself to discuss with at least a show of animation what each picture presents, and who can do little more than industriously wield the pointer, and inform his benighted audience that a tree is a tree, and a wild Indian an Indian?

What shall we say of the well-known writer, who, having no gift for extemporaneous speaking, mars the good effect of excellent il-

illustrations by neglecting to use the manuscript that would make his discourse coherent!

Perhaps mere notes would save him from helpless verbal floundering.

What shall we say of that misguided person, who, having at least eighty pictures to illustrate his lecture on Alaska, or some other far-away place, throws in about forty more, to show how he got there? Half a dozen to get the ship away from the dock at Seattle, half a dozen shots at the city as he steams away, a few more at passing vessels, another half dozen at the members of his party (in which he is careful to show up in most of the groups himself), a few pictures of the captain, and about a dozen showing the Indian villages of the British Columbia islands, as he steams kodaking along, and all of which have been kodaked by a dozen tourists on every steamer, every week for the past twenty years.

I witnessed such a performance at the afore-mentioned meeting in Philadelphia. The exhibitor of slides held the platform for an hour and a half, until even the picture-bewitched ornithologists were audibly in revolt.

How shall we use the lantern slide? Is it not possible for the lecturer to first present his matter, so that it will appeal to the mind of his audience, and then follow his discourse with a limited number of illustrations selected for their fitness rather than their beauty? It would be quite useless to show pictures first. No audience will stay after the last picture. The unceremonious exit stampede begins at once, even if the distinguished president of the society has risen to make some concluding remarks.

And how about manuscript which is unfortunately often necessary? There is no need for a slavish use of manuscript, if the matter is good and delivered in a vigorous manner. Many speakers use it effectively. Ingersoll never spoke without it, and Roosevelt uses it for all lengthy discourses.

Our museum lecturer should unquestionably devote more time to preparation. He should make his address worth hearing with-

out illustrations at all. He should be able to get the same applause for his matter that he gets for his pictures. When he does that he will be on a dignified basis himself, and will pay a long-deferred compliment to the intelligence of the audience, that it will be likely to appreciate.

I should like to see some of our museum men doing their platform work without pictures, and I am sure that some of them are capable of doing it. Most of those who try it should write out their lectures in full, and thus get the benefit of the work of arranging their matter and becoming familiar with it.

There must, of course, be reference to the manuscript, but the audience will not mind that if the subject is of real interest and the speaker deals with it in a forcible manner, impressing his hearers with the fact that they are listening to a man filled with his subject and sure that it is a good one. Lack of earnestness means that the audience will get weary or begin to slip out. I am sure that a good lecture half an hour long, followed by half the usual number of illustrations, will be an improvement on the present method.

Should we not illustrate our lectures, and cease to lecture about our illustrations?

C. H. TOWNSEND

N. Y. AQUARIUM

RALPH STOCKMAN TARR

As Cornellians and former students of Professor Ralph Stockman Tarr we learn with sorrow of his death and extend to his family our heartfelt sympathy and condolence. We feel keenly the loss to the university of his unselfish service and forceful personality, and we regret that his brilliant contributions to geology and geography have been cut off at a time when they were most fruitful and convincing. Above all we deplore the loss of the personal influence which we have found so helpful and inspiring in his home, in the classroom and in the field. Those of us who have known him under the trying conditions of life in northern ice fields, where no hardship was too great to be cheerfully borne, can most fully

appreciate his devotion to the science he loved and the fineness and strength of his character.

CHARLES ROBERT SANGER

IN the untimely death of Professor Sanger, on February 25, 1912, the Faculty of Arts and Sciences of Harvard University lost a loyal and faithful member, the chemical laboratory of Harvard College an efficient director, and the class of 1881 a devoted secretary.

Charles Robert Sanger was born in Boston on August 31, 1860. He graduated from Harvard College in 1881, received the Harvard degree of Master of Arts in 1882, and attained that of Doctor of Philosophy in 1884. From 1881 to 1882 and again from 1884 to 1886, he was assistant in the chemical laboratory of Harvard College, but in 1886 he went to the United States Naval Academy at Annapolis, as professor of chemistry. Six years later he was called to Washington University, St. Louis, Mo., and remained there until 1899, when he came back to Harvard as assistant professor of chemistry. He was called here because his service as assistant in qualitative analysis fifteen years before had been so able that he was deemed the most suitable person to continue the instruction in this favorite course when Professor H. B. Hill was obliged by other duties to relinquish it. Professor Sanger's return to Harvard was appropriate; he had never lost interest in the varied phases of our university life even when duty called him elsewhere. No son of Harvard has ever worked, according to his opportunity, more loyally in her behalf.

When in 1903 Hill laid down his work for-

ever, Sanger was promoted to a full professorship, and on account of his marked executive ability and conscientious devotion, was the natural choice for the onerous directorship of the laboratory. Only those who have been privileged to work with him there can fully appreciate the extent to which he generously gave his time and thought in order to further the interests of all.

While first at Harvard as an assistant, he worked under Professor Hill on the constitution of pyromucic acid. In recent years he confined his work chiefly to the devising and perfecting of methods for the detection of minute quantities of arsenic, antimony and fluorine, as well as to the investigation of the chlorine derivatives of silicon and sulphur. Besides papers describing these researches, he wrote several laboratory manuals. His fine character was especially manifested in the great care he exercised in all his scientific work; he was determined that no untrue statement should ever escape his pen, and rigorous precautions and manifold repetitions of experiments doubtless prevented him from ranging over a wider field. As a teacher he tried to inculcate the same habits of methodical painstaking work which he possessed himself.

He was a Fellow of the American Academy of Arts and Sciences and a member of the American Chemical Society and the Deutsche Chemische Gesellschaft.

In 1886 he married Miss Almira Starkweather Horswell, who died in 1905, leaving three children. Five years later he married Miss Eleanor W. Davis, of Cambridge, who, with the children, survives him.

No one could watch his struggle against an insidious disease during these last years without a feeling of deep admiration for the courage with which he lectured and worked in spite of spasms of mortal pain and prostrating weakness; and the devotion and consideration of his classes was a striking testimony to the universal respect in which he was held.

SCIENTIFIC NOTES AND NEWS

SIR J. J. THOMSON has been appointed by King George V. a member of the order of merit. The other scientific men who are members of the order are Lord Rayleigh, Dr. A. R. Wallace and Sir William Crooks. The order has recently lost through death Sir Joseph Dalton Hooker and Lord Lister.

DR. GEORGE T. MOORE has been elected director of the Missouri Botanical Garden to fill the vacancy caused by the resignation of Dr. William Trelease.

It is expected that the Peter Bent Brigham Hospital, now under construction on land adjoining the Harvard Medical School, will be completed in October, 1912. Dr. Henry A. Christian, retiring dean of the Harvard Medical School, will be physician-in-chief, Dr. Harvey Cushing, of the Johns Hopkins Medical School, surgeon-in-chief, and Dr. H. B. Howard, superintendent.

PROFESSOR ARTHUR SEARLE, Phillips professor of astronomy at Harvard University, has presented his resignation after a teaching service at the university of forty-two years. He graduated from Harvard in 1856.

PROFESSOR JEAN GASTON DARBOUX and Professor Elias Metchnikoff have been elected honorary members of the Royal Irish Academy in the section of science.

DR. JUST LUCAS-CHAMPIONNIÈRE has been elected a member of the Paris Academy of Sciences in succession to the late Professor Lannelongue.

THE council of the British Iron and Steel Institute has awarded the Andrew Carnegie Gold Medal of the Institute to Dr. Paul Goehre, the metallurgist of Aachen.

DR. C. L. SHEAR, pathologist in the Bureau of Plant Industry, has sailed for Europe to spend several months in the investigation of fruit diseases.

DR. J. E. POGUE, assistant curator of mineralogy, U. S. National Museum, has returned to Washington after a three months' research and study trip in Europe.

DR. HERBERT M. EVANS, of the Johns Hopkins Medical School, has been granted leave of absence to go abroad to work in the laboratory of Professor Ehrlich, at Frankfort, during the coming summer.

DR. DOUGLASS WILSON JOHNSON, of Harvard University, who has recently been appointed associate professor of physiography at Columbia University, is spending a half year in Europe.

DR. FRANK BILLINGS, professor of medicine at the University of Chicago, has been appointed to provide the details of the program for the section of epilepsy of the State Conference of Charities and Corrections to be held in Chicago next October.

MR. E. J. MCCAUSTLAND, professor of municipal engineering in the State University of Washington, has been appointed a member of the State Board of Health. Professor McCaustland has for three years acted in the capacity of consulting sanitary engineer to the board.

IN the preliminary list of papers to be presented at the eighteenth international congress of Americanists to be held in London, beginning on May 27, there are titles from the United States by Dr. Franz Boas, of Columbia University; Dr. A. Hrdlicka, of the U. S. National Museum; Dr. Charles Peabody, of Harvard University; Mr. Stansbury Hagar, of New York.

PROFESSOR JOSEPH P. IDDINGS, of Washington, will deliver a course of lectures to the geological students of the Johns Hopkins University, on "The Problems of Petrographical Provinces." The lectures will be given during the last two weeks in April.

THE Rev. Caspar René Gregory, professor of theology in the University of Leipzig, has concluded a special course of lectures at Western Reserve University. The lectures included a series of six on the subject "Five Hundred Years of Science in Leipzig."

THE Society for Biological Research of the University of Pittsburgh held, on March 20, its second special meeting for the year 1911-12, at which time Dr. Robert Russell Bensley,

director of the Hull Anatomical Laboratories of the University of Chicago, gave an address on "The Structure of the Pancreas and its bearing on the Islet Theory of Diabetes."

THE twentieth "James Forrest" lecture will be delivered at the Institution of Civil Engineers on April 19, by Mr. H. R. Arnulph Mallock, F.R.S., his subject being "Aerial Flight."

SIR WILLIAM MACEWEN will give an address on Lord Lister at the meeting of the Royal Institution of Great Britain on Friday evening, June 7.

A PORTRAIT bust of the late Sir Joseph Hooker, from a sitting taken just before his death, has been completed by Mr. Pennachine.

THE funeral of Dr. Thomas H. Montgomery, Jr., professor of zoology in the University of Pennsylvania, was held on Friday, March 22, at St. Mary's Episcopal Church. The honorary pallbearers were: Provost Smith, of the University of Pennsylvania; ex-Provost Charles C. Harrison; Professor E. G. Conklin, of Princeton University; Professor G. H. Parker, of Harvard University; Professor J. P. Moore, of the University of Pennsylvania; Professor W. M. Wheeler, of Harvard University; Professor William R. Newbold, of the University of Pennsylvania; William S. Morris and Professor Philip P. Calvert, of the University of Pennsylvania.

DR. JAMES RUFUS TRYON, formerly medical director of the navy, retired with the relative rank of rear-admiral, has died at the age of eighty-two years.

THE late Lord Wandsworth has bequeathed over a million pounds to establish an orphanage and school; the will also contains a bequest of £10,000 for medical research.

MISS HELEN SWINDELLS, of Southport, has bequeathed £5,000 to the University of Manchester for cancer research, and £5,000 to the benevolent fund of the Institution of Civil Engineers.

THE John Hay Library at Brown University will be augmented by a collection of seven thousand volumes on engineering subjects,

the gift of Mr. Elmer L. Corthell, the hydraulic and waterways engineer. The gift of the Corthell Library, as it is to be known, carries with it an endowment fund of \$5,000.

A SERIES of prizes is offered by a member of the Torrey Botanical Club for the best popular article on some feature of the vegetation of the local flora range. The prizes will be as follows: (1) A first prize of \$25; (2) a second prize of \$15; (3) for the five next best articles, a year's subscription to *Torreyia*. (Offered by the club.) The competition is open to all amateurs, school teachers and others not on the staff of a botanic garden, college or university.

THE fifth session of the Graduate School of Agriculture will be held under the auspices of the Association of American Agricultural Colleges and Experiment Stations, at the Michigan Agricultural College, East Lansing, Mich., July 1-26, 1912. Director A. C. True, of the United States Office of Experiment Stations, will be dean of the school and the faculty, as usual, will consist of some of the leading scientific men from the United States Department of Agriculture, the American agricultural colleges and experiment stations, other American universities and European institutions. Two lecturers have been secured from England, Dr. A. D. Hall, of the Rothamsted Experiment Station, and Professor F. H. A. Marshall, Christ College, Cambridge University. This school is open only to college graduates who want to pursue advanced work in agriculture. Graduate courses will be given under the general head of soils and plant physiology, animal physiology, agronomy, horticulture, swine husbandry, poultry husbandry, beef and dairy cattle, rural engineering and rural economics. Among the more important topics that will be given consideration at this time are the part played by the soil solution in the nutrition of plants, the relation of the physiology of plants to the soil problem, colloids in relation to soil fertility and soil bacteriology, zootechnical problems in relation to the physiology of the cell, the physiology of reproduction and the biology of sex, plant production

problems in relation to plant breeding and adaptation, problems dealing with the transportation, handling and storing of fruit, rural sanitation, road making, rural social surveys and rural festivals as agencies for social contact.

THE department of electrical engineering of the Massachusetts Institute of Technology has under way an important investigation on the adaptability of electric vehicles for trucking purposes, more especially with reference to the conditions in Boston and its vicinity. Mr. H. F. Thomson, the research associate, in carrying on this work, is making substantial progress in the inquiry. The inquiry is directed along several particular lines, including cost of the service, convenience of the service, difficulties and expenses due to the delays in loading and unloading at freight houses and the like, delays caused by drivers, and corresponding matters. The railroads entering Boston are cooperating with the part of the investigation relating to time occupied in loading and unloading trucks at the freight houses, including the time occupied in getting to the loading platform. The freight house conditions are being investigated by students of the department under the direction of Mr. Thomson. An appropriation for this work was made to the institution by the Edison Electric Illuminating Company of Boston. The research was begun about the middle of the year 1911 and is expected to extend beyond the year. It is expected to result in a report or series of reports on the relative merits of electric vehicles, other mechanical vehicles and horse vehicles for city and suburban delivery, for trucking and for the other purposes for which vehicles are used in the city and its suburbs. The department has had erected in Brookline a 700 foot span of number two naught bare stranded wire to represent a transmission span on towers, and has had this span under observation during the severe weather of this winter. The object is to learn more exactly the effects of ice, sleet and wind loads, and of temperature effects on the stresses imposed upon the wire and its supports. This research is being carried on by two students under the

direction of Professor Harold Pender. There are now a larger number of candidates for advanced degrees in electrical engineering than the department has ever previously seen, and the various branches of research which are being carried on are being constantly enlarged. This is in addition to the extended undergraduate work for which the department is notable.

THE copper mines of the United States have produced more than fifteen and a quarter billion pounds of copper, and of this total twelve mining districts have produced in excess of 100,000,000 pounds each, according to the United States Geological Survey. These twelve districts, located in eight states, have yielded 94.89 per cent. of the total output of the country since 1845, when the total product of the United States was but little more than 200,000 pounds. These districts are Butte, Mont., which has yielded 5,215,000,000 pounds, or 34.75 per cent. of the total production; Lake Superior, Mich., which has yielded 4,756,000,000 pounds; Bisbee, Ariz., 1,285,000,000 pounds; Morenci-Metcalf, Ariz., 882,700,000 pounds; Jerome, Ariz., 570,000,000 pounds; Bingham, Utah, 465,000,000 pounds; Shasta County, Cal., 336,000,000 pounds; Globe, Ariz., 334,700,000 pounds; Ducktown, Tenn., 211,700,000 pounds; Ely, Nev., 125,000,000 pounds; the foothill belt, California, 104,000,000 pounds; and Santa Rita, N. Mex. (where mining is believed to have been begun as far back as 1800), 103,000,000 pounds. All other districts have produced 804,300,000 pounds. It is interesting to note that the first ten of these districts are also the first ten largest producers to-day, although the order is slightly changed. These ten districts yielded 93.84 per cent. of the production for 1910. The United States is by far the greatest copper-producing country, our smelter output of copper in 1910 being 56.75 per cent. of the total for the world. Nearly every one of the leading copper-producing districts of the United States, according to the Geological Survey, made a record output within the three years preceding 1910, and nearly every one of them could have done so in 1910 so far as the ability of the mines

to produce the ore was concerned. An indifferent copper market and metallurgical difficulties, however, resulted in a decrease in the output for 1910 for several districts. The Survey's estimate on January 2, 1912, indicates a copper output for 1911 greater than that of 1910 and nearly equal to the record production of 1909. It is further stated that most of the companies are now in a position to maintain or even increase their present output, so that, if the consumption of the metal will permit, the production of copper in the United States for 1912 may be expected to show a marked increase. It is noteworthy that not one of the leading copper districts of the United States, several of which have been active producers for 30 years or more, has been worked out or shown a decrease in its ability to produce copper.

UNIVERSITY AND EDUCATIONAL NEWS

An anonymous gift of £100,000 has been made toward enabling the University of London to acquire a site north of the British Museum. The university has also received £60,000 from the Draper's Company for a senate house and administrative offices.

An anonymous donor has undertaken to give £20,000 to the University of Cambridge, to establish a chair of genetics, to be called the Balfour professorship of genetics, in honor of Mr. A. J. Balfour.

The nomination is announced of Dr. Edward H. Bradford, A.B. (Harvard, '89), professor of orthopedic surgery, to be dean of the Harvard Medical School.

PROFESSOR GEO. M. REED, of the University of Missouri, will have charge of the botanical work in the New York University during the summer session of 1912.

PROFESSOR H. A. WADSWORTH, of the department of forestry, University of Idaho, has resigned to accept a commission in the United States army. Mr. Erwin W. Cook, B.S. (Washburn), M.F. (Michigan), has been appointed instructor in forestry at the university. He has been forest assistant on the Salmon (Idaho) National Forest for the past two years.

DISCUSSION AND CORRESPONDENCE

PRINCIPLES OF WATER-POWER DEVELOPMENT

TO THE EDITOR OF SCIENCE: In presenting "Another View of the Principles of Water-Power Development,"¹ Professor Aldrich illustrates his idea of individual ownership of water in part by the pronouncement, "A man owns the water in his well, we all believe." He utterly ignores the case (occurring with increasing frequency as population and industrial use of water advance) in which the sinking of a larger or deeper well in the neighborhood robs the earlier well of its supply; and he equally ignores all other of those physical facts and relations concerning water which are of growing consequence and complexity as the uses of this primary resource increase and multiply.

Professor Aldrich illustrates his view of equity in the use of water by reference to power development at Shoshone Falls and Twin Falls, and declares that the only "part of the people" of the United States equitably interested in this use are "simply those who live within the range of power transmission, and are not more accessible to another source of power." He utterly ignores the paramount uses of water for domestic supply and the production of food; he ignores the patent fact that each year and each decade more and more of the water of Snake River is removed for these paramount purposes, and the certainty that within a generation practically all the water of Snake River valley will be consumed for these paramount purposes, leaving only a sufficient flow for natural sewerage with incidental power development and navigation; and he equally ignores the broad fact that "the people of Cape Cod, or of Washington, D. C.," who consume bread and beet sugar and other products of Snake River valley, have a most real interest in such utilization of the waters of that river as will best promote normal production and industrial development—i. e., as will best contribute to the general welfare. Perhaps the clearest indication of Professor Aldrich's no-

¹ SCIENCE, March 1, 1912, pp. 338-340.

tion as to equities in water appears in the pronouncement that under common ownership "the general government should collect as a tax" on all users of water amounts which may be defined broadly as corresponding to the railway standard of "what the traffic will bear"; he ignores the fundamental economic principle that while common ownership implies the right to impose conditions of distribution and use, it involves primarily the obligation to minimize taxes or other costs of distribution in the common interest.

In pointing his views as to the finality of legal relations already developed in the west, Professor Aldrich declares, "Every western state has voluminous laws on the subject, and ten times more voluminous legal decisions on those laws." Were his familiarity and sympathy with the west still greater than he professes, he would realize that the Idaho water law is better than that of Wyoming after which it was modeled, that the later Oregon law is still better, and that the California water law enacted a few months ago is the best of all, since with each passing year growing knowledge as to physical facts and relations, increasing population and industries, and concurrently advancing standards of equity fall into closer accord—indeed he would realize that the very principles he criticizes are the outcome of experience in the west, where the natural water supply is so meager that it is necessarily measured and apportioned and utilized more carefully than in any humid land, and might even learn that the proposition *All the water belongs to all the People* was first crystallized and expressed through the National Irrigation Congress (an essentially western organization, made up of western men, dominated by western ideas) at a meeting in Spokane wherein the preponderating representation was from Washington, Idaho, Montana and Oregon.

To those unfamiliar with the situation it may be of interest to know that two opposing views concerning the administration of water and other resources have come up in the western states; the formerly prevalent but now minority view is that the resources shall

be exploited for the private profit of those who acquired possession before their value was realized; the later view, already held by the great majority, is that the resources shall be developed, conserved against needless destruction, and utilized in the common interest, under customs and laws established primarily by communities, secondarily, by states, and finally, as need arises, by the federal government. On these opposing views Professor Aldrich contributes polemics, which may be needful pending more specific knowledge; but it is to be regretted that he does not contribute a fact, a figure, a principle, or any other iota of that definite foundation on which alone scientific discussion may fitly rest, and on which sound legislation may eventually be erected—unless, indeed, he is right in his remarkable main contention that the western states, commonly considered the most actively-growing part of the country, are already so bound by statutes and decisions that further progress is impossible.

W J MCGEE

DR. RADOSAVLJEVICH'S "CRITIQUE" OF PROFESSOR BOAS

TO THE EDITOR OF SCIENCE: The number of the *American Anthropologist* just issued from the press (Vol. 13, 1911, No. 3) contains an article by Dr. Paul R. Radosavljevich entitled "Professor Boas's New Theory of the Form of the Head—a Critical Contribution to School Anthropology" (pp. 394-436). The admission of such an article into a respectable scientific journal seems to have resulted from a misapplication of the praiseworthy editorial principle that no student, however high his professional standing, shall be exempt from the most rigorous criticism on the part of the least of his fellow-workers. In the present instance, however, we have to deal not with a critique, but with a lampoon. The extraordinary character of Dr. Radosavljevich's paper requires an immediate reply, especially in view of Professor Boas's protracted stay in Mexico. Without desiring to forestall a fuller rejoinder by those more

competent to speak on the subjects under discussion, I regard it as necessary to illuminate in a preliminary way the nature of the "contribution" that seeks to brand one of the most critical scientific thinkers of the age as an irresponsible sensation-monger incapable of the most obvious precautions against errors of observation and interpretation. I will confine my attention to two points: (1) Dr. Radosavljevich's representation of Professor Boas's theory; (2) Radosavljevich's refutation of "Boas's first conclusion."

1. Dr. Radosavljevich writes (p. 405):

On page 32 of his [Boas's] report¹ he says that no evidence has been collected which would show an actual change in type due to the direct influence of environment, because the type of immigrants changes from year to year, owing to a selection which is dependent upon the economic conditions of our country, "far-reaching" changes in "type" which "can not be ascribed to selection or mixture." According to Boas the racial characteristics do not survive under the new social and climatic environment of America. We may therefore call Boas's theory the *environmental-economic* theory, the first theory of its kind; *environmental*, because it claims that the descendants of the European immigrants change their type "even in the first generation almost entirely." . . .

The theory may be called *economic*, because it claims that the panics of 1893 and 1907 caused a "sudden decrease in the general physical development of immigrants" and a "sudden" increase in the cephalic index.

A comparison of page 32 of Boas's report with the exposition just quoted at once absolves Dr. Radosavljevich from the charge of morbid devotion to accuracy of statement. On page 32 Professor Boas has nothing to say of the economic conditions of our country; nor is there a word on the causal connection between changes due to environment and the change in type of immigrants due to economic selection. In the first paragraph of page 32 Professor Boas states that the form of the body seems to be the most stable characteristic of any given race, but that Gould and Baxter,

¹"Changes in Bodily Form of Descendants of Immigrants," Washington, 1910.

Bowditch and others have found indications that under more favorable environment the physical development of a race may improve. Then follows the statement:

No evidence, however, has been collected which would show an actual change in type due to the influence of environment. Where changes of this kind seem to occur—as, for instance, in a comparison of the types of city population and country population in southern Germany and in Italy—the inclination of observers has been rather to attribute the difference either to the selective elimination of the weaker type or to the immigration of different types.

After a brief transitional sentence Boas then, in the final paragraph of the page, proceeds to characterize the contribution to knowledge made through his own investigation as compared with the contributions of his predecessors as previously summarized: while *they* had collected no evidence showing an actual change in type due to environment, but were inclined to ascribe changes to selection or mixture, *Boas* has demonstrated "a far-reaching change in the type—a change which can not be ascribed to selection or mixture, but which can only be explained as due directly to the influence of environment."

Our comparison makes it impossible to characterize Dr. Radosavljevich's exposition of page 32 in parliamentary language.

What, then, of Boas's "economic" theory? This, it may be well to mention, is a favorite butt of Radosavljevichian sarcasm (pp. 415, 420, 426). The fact of the matter is that, on page 28 of his "Report," Boas states that after the panic of 1893 a sudden decrease in the general development of immigrants occurred and persisted for several years; that a similar change *seems* to have occurred after the panic of 1907, and that his observations on this point have been confined to East European Hebrews. On page 30 we learn that among the questions not yet studied by Boas, is "the important problem of the selection which takes place during the period of immigration, and which is indicated by the change of type of immigrants after the panics of 1893 and 1907." On page 39 Boas again calls at-

tention to the drop of all absolute measurements of foreign-born Hebrews arriving in America after 1894.

An attempt to combine all the material, adult and children, for these years, brings out the sudden drop after 1893 even more clearly; and a similar phenomenon is repeated between the years 1907 and 1909: For this reason I am inclined to believe that the type of immigrants is directly affected by financial panics. This can be due only to a selection which takes place in Europe, and which may also be affected by the return emigration from the United States to Europe. The material, so far as it has been discussed, does not give a definite answer to this important question, the solution of which would require a series of parallel measurements taken in Europe.

Were there any possibility of misunderstanding the foregoing statements, it would be eliminated by the legend of Boas's Fig. 17:

The most striking feature of the diagram is the general decrease in all measurements in the period following the year 1894, which indicates that the arrivals during the period following the panic of 1893 were underdeveloped in every direction.

When Radosavljevich reproaches Boas for not studying the effect of American soil and financial panics on the *same* individuals during a period of time representing the age of his subjects (p. 420 f.), he shows that he has not the faintest notion of what Boas is discussing in connection with financial panics.

Unfortunately those who attended a meeting of the American Ethnological Society on March 27, 1911, will be unable to accept this relatively favorable view of Dr. Radosavljevich's attitude towards the "economic" theory. For at that meeting Dr. Radosavljevich, in the course of a lengthy paper, presented a temperate, and formally quite unexceptionable, criticism of what he conceived to be Boas's economic theory. In a discussion Professor Boas pointed out that the criticism rested on a misunderstanding, and Dr. Radosavljevich then—in the presence of Professor Farrand, Drs. Spinden, Goldenweiser and Fishberg, the present writer, and other anthropologists—publicly apologized for his misinterpretation with much profusion of courtesy.

This circumstance seems to have escaped Dr. Radosavljevich's memory.

2. Dr. Radosavljevich asserts that Boas's own observations do not support his theory of a change of type (pp. 406-411, 429). For, says he,

All Hebrews (born in America and in different countries of Europe) are of the same sub-brachycephalic type. Not one age, not one sex, not one individual of Hebrew nativity is represented either by dolichocephalic or by mesocephalic type. The same is true in its way of the Sicilians measured. They are of a high mesocephalic type, both in America and in Europe.

It would be difficult to find in the whole range of scientific literature a more naïve instance of conceptual realism. For Radosavljevich the conventional classificatory divisions of head forms obviously have an absolute biological value. Boas states that foreign-born Hebrews have an index of 84, American-born Hebrews an index of 81. That this difference is a *real* difference results, of course, not from a mere inspection of these two figures, but from the customary statistical treatment of the series involved. But Radosavljevich's mind is undebauched by statistical method. What matters a change of 3 units in the cephalic index so long as "the bulk of both American-born and foreign-born Hebrew boys and girls belong to the same brachycephalic (or rather to the sub-brachycephalic) type"? Sub-brachycephaly ranges from 80 to 86.9. Had Boas found that American-born Hebrews had an index of 79.9, then, we may presume, Dr. Radosavljevich would have hailed the result as the discovery of an actual change of type, provided only that foreign-born Hebrews had an index of 80.001!

As the subject of head forms has an esoteric tang, it may be well to illustrate the logical point at issue by statures. Suppose that we class men below 5 feet 8 in. as short, above 6 feet as tall, and between these limits as middle-sized. Assume further that a race which in Europe has an average height of 5 feet 3 in. adds three inches to its stature in America. Then, according to the classifica-

tory realism of Dr. Radosavljevich, we should not be justified in asserting that a difference in type had taken place, for both statures, 5 feet 3 in. and 5 feet 6 in. fall within our category of shortness. As a matter of fact, it depends entirely on the statistical comparison of foreign-born and American-born individuals (involving the numbers of cases and standard deviations) whether the difference is a real one. A difference of 1 cm. may constitute an actual difference of type in the statistical sense.² Dr. Radosavljevich's inability to grasp what Boas means by "a change of type" and in his insistence on dragging in the irrelevant conventional classification of head forms must be regarded as pathetic.

I believe I have sufficiently elucidated the nature of Dr. Radosavljevich's contribution. I should gladly have refrained from any comment, were it not for the regrettable fact that there are so few anthropologists in America who are able to form an intelligent opinion on the issues involved, and that the uninitiated are liable to be deceived by Dr. Radosavljevich's imposing array of bibliographic references.

ROBERT H. LOWIE

AMERICAN MUSEUM OF NATURAL HISTORY

REPORT OF THE SEAL COMMISSION

TO THE EDITOR OF SCIENCE: In a recent debate in the House of Representatives on the fur seal bill, Congressman N. E. Randall, of Iowa, made the following statement, as reported in the *Record*, p. 2158:

Dr. David Starr Jordan wrote a book. He appropriated this chart of Professor Elliott's and incorporated it into his book as his own. Dr. William T. Hornaday, of New York, subsequently wrote a book. He saw Dr. Jordan's book containing this Elliott chart, and Dr. Hornaday reproduced that chart in his book crediting it to Dr. Jordan. About that time Professor Elliott became alive to the situation and wrote a letter of protest to David Starr Jordan. Dr. Jordan was compelled to admit the plagiarism of the chart and that Dr. Elliott was the author of it and the discoverer of the facts it exhibits.

² Westergaard, "Die Grundsätze der Theorie der Statistik" (Jena, 1890), p. 187.

This charge of plagiarism is so specific and circumstantial that it demands an answer. The chart referred to is doubtless the one printed in the back of the first preliminary report of the Seal Commission of 1896-7, of which Dr. Jordan was chairman. As secretary of the commission I am familiar with the circumstances. When the manuscript of the report was submitted to the Treasury Department, Mr. Charles S. Hamlin, then assistant secretary, suggested the advisability of a chart or map giving the relative location of the Seal Islands and showing the general migration route of the herd. The commission had in process of preparation, under the direction of Mr. Charles H. Townsend, for its final report, an authentic chart of the herd's migration route to be platted from the log records of numerous sealing vessels, but this could not be got ready in time for the preliminary report, and Dr. Jordan was averse to publishing a merely conjectural chart. The assistant secretary held that such a chart, even if not strictly accurate, would be useful to the general reader and indicated how it could be readily compiled from the records of the department. Dr. Jordan acquiesced in this arrangement and left the entire matter of the preparation and printing of the map to the department. He did not see the chart until it appeared in the printed report. That the chart appears without legend as to authorship or source was explained by the fact that it was prepared by the department's own draftsmen and from its own data. Furthermore, the chart contains no information which was not at that time the common property of any one having a general knowledge of the subject. It consisted of a series of curved lines emanating from the passes of the Aleutian Islands, sweeping down through the North Pacific Ocean, veering toward the American coast and returning to the Aleutian passes and thence to the Pribilof Islands, the winter months being printed in the series of lines at points supposed to mark the progress of the herd. How completely this chart was superseded by Mr. Townsend's records platted from some 120 sealing logs will be seen by reference to his

chart published in volume 3, p. 234, of the final report of the commission. That any one should claim authorship for this discarded chart is remarkable. Certainly Dr. Jordan never has. When, after a number of years, Mr. Elliott laid claim to it, Dr. Jordan was assured by the Treasury Department that it was under no obligations to Mr. Elliott for the chart.

QUOTATIONS

LORD LISTER AND WESTMINSTER ABBEY

It is only by reason of Lord Lister's known wish that he is not buried in Westminster Abbey. Yesterday an impressive service was held there to give expression to feelings of gratitude and thankfulness, and in memory of what he has done for mankind. Posterity does not always confirm the opinion of contemporaries as to those meriting such honor. The Abbey has its monuments of the pseudo-great, statutes of justly forgotten worthies, inscriptions pretentious if not mendacious. If there were a centennial expurgation, much might be cast out. But of this we may be assured, that it would have been matter of enduring surprise and reproach if no place had been offered in the Abbey for the great healer who has passed away. It is crowded with memories or associations of strife and enmities, and heroism displayed therein. The world does not fight every day as of old, at all events with enemies of one's own race; and so, as time goes on, if the Abbey is to continue to be the place where the nation's chief worthies repose or where it bids them farewell, it must be associated more and more with the heroes and victims of peace. He who cured where death had been certain, who brought hope where there had been despair; he who found surgery, as some thought, little more than the art of killing quickly those who would have died slowly, and who transformed it into a wellnigh miraculously beneficent agency for the relief of human suffering—he, of all others, merits such honor. We are not under-

valuing the ceremony of yesterday—one of the most impressive ever held in the Abbey; one in which every one present was a sincere mourner—in saying that there will be many unseen and nameless tributes of gratitude which Lord Lister would have valued even more. In every hospital, the world over, must be some who, the subjects of operations successfully conducted by reason of his methods, will, on the news of his death, think of him with gratitude. The victories of war are fleeting; they may be over in a day or an hour; and some of the greatest of them are local in their effects. But those of the healing art, such as were due to Lister, are renewed everywhere and for all time.

There exists no means of measuring, even approximately, the amount of pain and suffering in the world at any given time. We can not doubt that it varies from age to age; and there is no certainty that it decreases with the growing complexity of our every-day life. While some primitive sources of suffering, such as famine, pestilence and war, may diminish, others may increase. The hurry and tear and wear incident to our civilization make more calls upon the nerves; they are always on the stretch; and it is not improbable that we are more susceptible to pain than were our rude ancestors. It is the drawback of so many discoveries and inventions that they take away from us almost as much as they give; they create unrest and multiply needs; they spread the limited capacity for pleasure over many objects, to the impairment in the end, it may be, of the total amount of enjoyment; and the greatest marvels of ingenuity may leave us no richer in essentials than before. The inventor who robs us of nothing, whose gifts are all pure gain, is the healer who has found secrets before unknown. In life the presence of pain is the mystery of mysteries. The moralist offers us his feeble explanations, and tells us that without sacrifice no permanent satisfaction or truly good results can be attained; that, to use a common and unconvincing expression, it is a masterful and wholesome discipline; that, to cite the words of one who in all sin-

cerity expounded this unsatisfying solution, by pain we are "driven ever onwards." Such consolations have stifled few cries or groans. The fact borne in upon all who were familiar with surgery in the pre-Lister days was that there was so much suffering to all appearance sheer waste; a heavy price was paid and nothing was gained; the way through discomfort and distress lay to more of both. And so we all instinctively place masters of the healing art, certainly those who have found new remedies and effective methods, among the great benefactors of men. They, and almost they alone, among inventors and discoverers have given much and taken from us nothing.

One further reflection must have been present to many in the Abbey yesterday. Lord Lister's discoveries and methods have opened up possibilities of still further advances, scarcely dreamed of before. The surgeon whom our ancestors regarded as the most highly paid of executioners is seen to be the possessor of an art the future of which is limitless. Lister and his coadjutors have shown what are the enemies to be guarded against and how they are to be encountered. He has opened a way which will be pursued, it may be confidently expected, with signal results. To use the words of the anthem yesterday, "His body is buried in peace, but his name liveth for evermore"; chiefly, no doubt, for his beneficent discoveries, but partly also by reason of the memory of his character, for all time the type of the faithful servant of science. Good as well as great, modest, genial, zealous in the interest of his patients, seeking truth unweariedly and calmly, he will, we do not doubt, be the model and example of men who will carry the art of healing far beyond the point which it has to-day reached.—The *London Times*.

SCIENTIFIC BOOKS

The Chemistry of the Radio-Elements. By FREDERICK SODDY. Longmans, Green and Co. 1911. Pp. 92.

There is probably no branch of modern science which has offered so great an attraction to the casual student as the subject of radio-

activity, and there is certainly none which has afforded a more unrestricted field to the ambitious author who, with but little firsthand information, has been eager to popularize the views of others or to support enthusiastically unsound doctrines based on a wholly insufficient knowledge of the fundamental principles or the value of experimental evidence. It is a pleasure therefore to be able to welcome the appearance of Mr. Soddy's book, written as it is by one who possesses so wide a knowledge of the topics treated and who has played so important and prominent a part in the development of the subject of radioactivity.

The book begins with a brief statement of the scope and objects of radio-chemistry. This is followed by a general discussion of the phenomena of radioactivity, the first discovery by Becquerel of the emission of characteristic radiations by uranium compounds, the general properties of these radiations, and the extension of our knowledge which resulted from the pioneer work of Madame and Monsieur Curie. To the novice in the subject, the text at this point is likely to lead to a somewhat exaggerated notion of the part played by the Curies in the development of the general theory, but difficulties of this sort are apt to arise in any attempt at a condensed treatment of so complex a subject, and the author has succeeded in preparing a distinctly instructive outline in which the more important facts are presented in a clear and orderly fashion. The characteristic differences in the relative permanence or stability of the different radio-elements are mentioned, the production by certain of these of gaseous radioactive elements or emanations is described, and the properties of the emanations themselves are briefly considered. Then follows a discussion of the interesting experiments on the radioactivity of thorium salts, which led to the formulation of the disintegration theory, and an outline is given of this theory in its more important phases.

The next topic treated is the general nature of the three types of radiation, the alpha, the beta and the gamma rays. The characteristic

properties of each of these are considered at some length and the evidence pointing to the identity of the alpha particles with charged helium atoms is clearly presented.

The second chapter is devoted to the radioactive constants and periods of average life of the radio-elements. Here, as elsewhere in the pages which follow, Mr. Soddy has shown a preference for denoting the relative stabilities of the different radio-elements by their so-called "average life" periods rather than by their "half-value" periods adopted and used by nearly (if not quite) all the other writers on the subject. To the reviewer the "average life" of a radio-element is merely the reciprocal of the constant of radioactive change, an occasionally convenient mathematical expression having little or no objective significance. Mr. Soddy defines it as "the sum of the separate periods of future existence of all the individual atoms divided by the number in existence at the starting point." The "half-value" period, on the other hand, is the time required for exactly one half of any given quantity of a radioactive substance to disintegrate or be transformed into other types of matter.

A very interesting and suggestive section on radioactive equilibrium completes the second chapter.

The title of the third chapter is the "Classification and Nomenclature of the Radio-elements.—Analogies Between the Three Disintegration Series," but the subjects covered are much more comprehensive than this heading would imply and include many topics of extreme interest and importance. In the opinion of the reviewer this chapter is the most valuable and illuminating portion of the entire book and the one to be most profitably extended and developed in future editions. It contains the essence of a new branch of science, radiochemistry, and Mr. Soddy has succeeded in collecting together and presenting in a relatively small space, and in a very impressive and convincing manner, much that has previously been accessible only in scattered scientific publications of his own and of other workers in this field of scientific in-

quiry. Thus, for example, the conditions determining the possibility of separating and isolating any given radio-element in a state of comparative purity are briefly but comprehensively considered, the general methods of obtaining the so-called "active deposits"—the solid radioactive products resulting from the disintegration of the gaseous emanations—are outlined, and the inferences to be drawn as to the true chemical nature of the different radio-elements from a knowledge of the behavior of these when mixed with large proportions of their apparent chemical analogues are discussed in some detail.

This general introductory matter occupies in all only thirty pages and one can not avoid a feeling of regret that it was not found practical to extend it still further. It is followed by a systematic presentation of the more important physical and chemical properties of the thirty-odd radio-elements thus far identified arranged in an orderly fashion under the separate headings, "Uranium," "Uranium X," "Ionium," "Radium," etc.

Mr. Soddy has provided us with a very valuable book of its kind, unique in respect to the field which it covers. It need scarcely be added that no one who desires to work intelligently in this modern branch of chemistry can well afford to be without it.

B. B. BOLTWOOD

Stability in Aviation: an Introduction to Dynamical Stability as Applied to the Motion of Aeroplanes. By Professor G. H. BRYAN, Sc.D., F.R.S. Macmillan and Co. 1911. Pp. xi + 192. Price, \$2.00.

Any one seriously at work on the theory or the art of aviation would profit by reading what he can of this book, though precious few will have both the time and the ability wholly to master it and probably none, not even the author of it himself, fully to solve all the difficult problems it sets.

The first chapter gives, in 18 pages of concise non-mathematical language, a summary of existing knowledge on aeroplane stability, and incidentally forms a good mental appetizer for the very solid intellectual courses that fol-

low. But the busy man and the man without mathematical training must take the statements of the next 8 chapters, or 146 pages, on faith. The essential equations in the greatest abundance are there and their meanings explained, but checking them all up would be no easy task.

The general conclusions all this mathematical work leads to are given in a short chapter of only 6 pages, and in another place 20 separate theses are proposed that should set many young men at work on problems that are both new and useful in applied mathematics.

But, the "practical" man will say, what's the use of all this theory and all these mathematical equations? The answer in this case as in all similar cases is: To tell the practical man what to practise, what experiments are needed and what are not, what general type of machine is likely to succeed and what is certain to fail; to save him from needless blundering and to assure him of results and how to obtain them that he never did and never would even dream of.

Professor Bryan's book is especially adapted to the needs of advanced students in physics, applied mathematics and certain branches of engineering, and richly deserves a place in both mathematical and physical libraries.

W. J. HUMPHREYS

Non-Marine Mollusca of Patagonia. By HENRY A. PILSBRY. Reports Princeton University Expeditions to Patagonia, Vol. III., Part V.

This important work was issued in 1911, but there is nothing about the separate issue to indicate the date. It deals with the non-marine molluscs of Tierra del Fuego and Patagonia as far north as the thirty-ninth parallel, and is most beautifully illustrated by colored and uncolored plates. Of certain families, all the South American forms are listed. At the end is given a most interesting discussion of the characteristics and origin of the South American Mollusca.

The poverty of the Patagonian fauna in land snails is remarkable. Seven Endodon-

tidae and the two Zonitidae have been described, all small. Their precise affinities are uncertain, from lack of knowledge of the internal anatomy. A small slug has been reported, perhaps introduced. *Succinea* is represented by several species, one of them abundant. No doubt other species will be discovered, but certainly no other part of the world, in a similar latitude, has such a meager representation of land shells. With the fresh-water snails it is somewhat different, the fauna not only containing a number of species of the families familiar in the northern hemisphere, but also a rich representation of the Chiliniidae, a family confined to the temperate and cold zones of South America. All the Chiliniids east of the Andes are discussed, with four fine plates. Six colored plates are devoted to the Amnicolid genus *Potamolithus*, of which a complete revision is given. There is a complete list of the South American Sphæriidae, with descriptions of several species. Thus the work, while ostensibly a report on the Princeton collections, is in reality much more extensive and important than the title would suggest.

All zoologists will be interested in the general discussion of the fauna. Dr. Pilsbry recognizes a Cœnogæic or northern group of families, and an Eogæic or southern group, the latter having "occupied chiefly the Gondwana continent, including a large part of South America, tropical and South Africa, and stretching in a great arch, possibly at no time perfect, to peninsular India and Australia." It is in this second group that he would place the Mutelidae, Ampullariidae, Acavidæ, Bulimulidae, Achatinidae, Streptaxidae, etc. With regard to Antarctica, it is shown that the non-marine molluscs, taken by themselves, indicate that: (1) "There is no evidence that Antarctica was ever an evolution or radiation center for non-marine mollusks, though there is some evidence showing that it served as a highway for migration." (2) "There is some evidence of migration from South America to Australia, but at present no evidence of a counter movement to South America." (3) "Nothing in the dis-

tribution of mollusks would lead to the hypothesis that South Africa has ever been connected with Antarctica and thereby indirectly with southern South America." It is finally concluded that "the South American molluscan fauna is traceable to two sources: an ancient southern continent lying across the south Atlantic and enduring from at least Palæozoic to near the end of Cretaceous time, and to Miocene and Pliocene to recent connections with the middle American area." Since the appearance of Dr. Pilsbry's work, Dr. Ortmann has published the anatomy of the Australian fresh-water mussel *Hyridella*, showing that it is indeed allied to the South American *Diplodon*, further suggesting communication between these areas. All these matters no doubt deserve fuller discussion. According to Dr. Schuchert's recent map, North America was rather broadly continuous with South in the late Comanchic period, and remained so during the Cretaceous. During the early and middle Tertiary this connection was interrupted; but with the coming of the Pliocene, according to Dr. H. F. Osborn, it was renewed, and has continued to the present day. There should be, therefore, two elements in the neotropical fauna, both derived from the north, one of Mesozoic age, the other late Tertiary. The latter is recognized by Dr. Pilsbry, but where is the former? Is it not, at least in part, the "Eogæic" group of families? Is there anything in the Molluscan fauna which really supports the idea of a gigantic Gondwana continent, or any other body of land crossing the Atlantic or Pacific? It is true that molluscs are likely to travel slowly, the pace of the snail is proverbial; but they are ancient and have had time enough. *Cochlicopa lubrica*, assuredly a member of a Palæarctic group, has contrived to crawl all the way from the old world to New Mexico within the lifetime of its specific type, the animal being quite the same in Europe as in America. There is surely nothing in the distribution of snails which might not be explained by migrations from the north, and as to the negative evidence based on northern palæontology, it is clearly not worth much. As Dr. Pilsbry truly says, "the rarity of land and

fresh-water shells as fossils, and the great antiquity of the family groups, renders the question very intricate." On the other side, there is the fact that the Chiliniæ, certainly of no recent origin, have apparently never left South America. There are reasons for thinking that in Palæozoic times the Antarctic land mass supported a more or less luxuriant flora, with a corresponding fauna, which doubtless eventually spread in part to other regions of the earth.¹ It is even possible that the Chiliniæ came from this source; but we can hardly expect to find much, if any, clue to the components of this antarctic biota in the present distribution of life, for the simple reason that there has been abundant time for it to spread over the whole earth, wherever the conditions permitted.

With regard to the northern route from South America to Africa or Australia, or *vice versa*, it should be clearly understood that it is not necessary for a whole fauna to migrate, to account for such faunal resemblances as exist. Thus the Characinid fishes are to-day abundantly represented in the Ethiopian and Neotropical regions, but do not exist elsewhere except that one or two species enter the southwestern part of the nearctic. No fossil Characinids have been found in the north. The naïve conception of a transatlantic bridge on which the Characinids freely traveled appeals to the imagination, but it is found on examination that only one part of the African Characinid fauna is really at all close to the South American, while the latter has very important elements totally diverse from the African series. The indications are that the Characinids arose in the neotropical, and at some very remote period reached Africa, where they developed a type (Ichthyoborinæ + Distichodontinæ, probably to be regarded as a distinct family Distichodontidæ) entirely unique in some of its characters. At a much later time the Hydrocyonine Characinids appear to have arrived in Africa, the immigrants consisting perhaps of not more than one or two species, which during a relatively brief period overran the northern hemisphere, leav-

¹ See, for instance, Seward, *Quarterly Journal Geological Society*, August, 1897, pp. 335-338.

ing perhaps no fossil remains which will ever be detected.*

SPECIAL ARTICLES

NOTE ON THE UPPER EOCENE TITANOTHEROID
TELMATHERIUM (?) INCISIVUM DOUG-
GLASS FROM THE UINTA BASIN

IN describing the type of this species (a skull, No. 2,398 Carnegie Museum Catalogue of Vertebrate Fossils) Mr. Douglass¹ said:

I think that this skull represents a different genus from *Telmatherium*, but I prefer to place it provisionally here rather than establish another genus.

Through the courtesy of Mr. Douglass, Director Holland and Professor Osborn, the present writer has been enabled to compare this type with the extensive Eocene Titanotherid material in the American Museum of Natural History. With the approval of these gentlemen the species *Telmatherium* (?) *incisivum* Douglass is hereby made the type of a new genus or subgenus *Sthenodectes*.² This genus is distinguished from *Telmatherium ultimum* Osborn by the following assemblage of characters: (1) The incisors are far larger and more advanced in evolution, i¹ being closely appressed to its fellow in the median line, with anterior face elongate, anterointernal tip blunt, median basin large, posterior wall or cingulum very massive; i², i³ extremely large with low recurved tips and very heavy posterior cingula. (2) The postcanine diastema is reduced or absent. (3) Superior premolars 2, 3, 4 are much more advanced than in *T. ultimum*, having very heavy internal cingula, pronounced external cingula, high slender internal cusps (deuterocones); p¹ especially is in a relatively advanced stage, as compared with *T. ultimum*. (4) The least

* The Cichlidae, with a very similar distribution, have left us beautifully preserved fossils of Eocene age in Wyoming, but not elsewhere.

¹ *Ann. Carnegie Mus.*, Vol. VI., No. 2, 1909, p. 305.

² *σθένος*, strength, *δενκτής*, a biter, in allusion to the great power and development of the incisors and canines.

transverse diameters of p⁴ and of the anterior lobe of m¹, are greater, that of m¹ much less, than in *T. ultimum*. (5) The basicranial region differs in many details, such as the apparent junction of the post-glenoid and post-tympanic processes below the auditory meatus. (6) The occiput is low with a sharp, long, sagittal crest. (7) The forehead is relatively wide. (8) The nasals taper distally.

From *Manteoceras* (especially *M. uintensis*) the genus under consideration is distinguished by: (1) The form and size of the incisors and canines, (2) the much more advanced stage of evolution of the premolars, (3) the shorter anteroposterior diameter of m¹, (4) the reduction of the post-canine diastema, (5) the arched and spreading zygomatics; etc.

From *Dolichorhinus* and *Mesatirhinus* it is separated by the shortness and relative breadth of the skull, the great size of the incisors, the relatively heavy zygomatics and many other details.

The genus or subgenus *Sthenodectes* is apparently allied to *Metarhinus* and may well be related to *Metarhinus earlei* Osborn from the Upper Washakie, which it resembles in important characters of the premolars and molars, form of the basis cranii and occiput, marked constriction of the face in front of the orbits as seen from above. The narrow tapering nasals and other characters also suggest affinity with *Metarhinus diploconus*. The type skull of *Sthenodectes incisivum* differs from all known *Metarhinus* material in the form and in the very large size of the incisors and canines, in the much stronger internal cingula on the premolars, stout zygomatics, junction of the post-glenoid and post-tympanic processes below the auditory meatus. The forms of the premaxillary and of the subnasal incisure also differ from those of *Metarhinus*. The supposed vacuities in the lachrymal region, although indicated on both sides, may be artifact.

WILLIAM K. GREGORY

OIL CONCENTRATION ABOUT SALT DOMES

IN several national, state and private publications the writer has called attention to the remarkable concretionary growth and bodily

movement upwards of huge masses of rock salt in Cenozoic deposits along the Gulf border. The bearing of the structures produced in the neighboring beds by such growths and movements on oil concentration was duly set forth in Bulletin 429 of the United States Geological Survey. Recently he has had the opportunity of testing the value of his "dome theory" for locating oil "pools" in a region far away from any known oil occurrences. Reference is here made to Pine Prairie, south central Louisiana, where the Myles Mineral Co. has had the courage to try out the theory and has discovered by the means a new oil field. The director writes "I consider this a most remarkable vindication of a theory originated by you, and we attribute a large measure of our success thus far to your advice."

Space should not be taken here to discuss the probable exact location of oil in connection with these domes; that is a matter depending largely on the approach of the salt dome to the surface, size, location, etc. These matters have been outlined at least in the U. S. Geological Survey Bulletin already referred to. But the location of oil by means of a theory unheard of ten years ago does seem worthy of record at this time. Another fact that should be impressed upon the mind of the public now is the absolute worthlessness of stock in companies putting down wells "near" the discovery well. This matter has, however, been discussed in Bulletin 429.

CORNELL UNIVERSITY

THE AMERICAN ASSOCIATION FOR THE
ADVANCEMENT OF SCIENCE
SECTION D

DR. J. A. HOLMES, director of the Bureau of Mines, was elected vice-president of the association and chairman of Section D for the next meeting, at Cleveland. Professor O. P. Hood was elected a member of the council for the Cleveland meeting and Major W. W. Crosby a member of the sectional committee for five years, *vice* Professor J. E. Boyd, whose term expired. Mr. W. Bowie represented the section in the general committee.

The meetings of the section were presided over by Vice-president C. S. Howe, of Cleveland. The section held its first session on Wednesday morning, December 27, at Georgetown Law School. Two sessions were held on Thursday at the same place. On Friday morning and afternoon the section met in the Institute for Industrial Research. On Saturday, visits of inspection, under the direction of Professor A. H. Blanchard, were made to the office of good roads and to the sites of actual road construction in the vicinity of Washington and Baltimore.

On Thursday afternoon, following the address of retiring Vice-president A. L. Rotch, the following resolutions were adopted:

WHEREAS, the new and important art of navigating the air requires for its proper development exclusive investigations in aerodynamics, and thorough comparative tests of practical aerial machines, and

WHEREAS, the Aero Club of America proposes to secure the endowment of a laboratory for such investigations and comparative tests, therefore be it

Resolved, That the Engineering Section of the American Association for the Advancement of Science expresses to the Aero Club of America its appreciation of the urgent need for such a laboratory, and heartily commends its efforts to secure an adequate endowment, and be it further

Resolved, That a copy of these resolutions be sent to the Aero Club of America, with best wishes for the success of its efforts.

On Friday afternoon, resolutions were adopted extending the thanks and appreciation of the section to Dr. A. S. Cushman, director of the Institute for Industrial Research, for the use of the laboratory for the meetings on that day. The secretary takes this occasion to express his appreciation of the valuable assistance of Dr. C. S. Howe and Professor A. H. Blanchard in securing papers for the program and to the members and non-members who contributed.

The Washington meeting of Section D was successful beyond expectations, the papers being valuable and interesting and the attendance at the sessions encouraging as to numbers and interest manifested.

Abstracts and titles are listed below by groups.

MISCELLANEOUS PAPERS AND TITLES

Analysis of the Deflections and Stresses in Reinforced Concrete Floor Slabs Constructed on

the Turner Mushroom System: H. T. EDDY, University of Minnesota.

Owing to the apparently irregular distribution of the reinforcement employed in this system and to the uncertainty as to the value of Poisson's ratio or lateral contraction for reinforced concrete, engineers have differed widely in their estimates of the strength and stiffness of this form of construction, and have distrusted the results of tests made to determine deflections. The author has in this paper given a complete rational analysis of this form of construction and derived simplified but closely approximate practical formulæ for the resistance and deflection of this slab, showing how the various constants depend upon the properties of the materials composing the slab and how their arrangement affects its strength and rigidity. Of these several constants Poisson's ratio is the most important. It is shown in the paper that the value of Poisson's ratio obtained from experiments upon ordinary test specimens of square or round cross section is necessarily much too small for material circumstances as is the reinforcement in a slab. The experimental results obtained from the deflection of mushroom slabs makes it probable that the proper value of Poisson's ratio for the reinforcement is nearly twice that obtained from ordinary test specimens. On this basis the theoretical results arrived at in the paper agree in a very striking and remarkable manner with the empirical formulæ which have been proposed to express the results of the numerous tests heretofore made on such slabs.

The Primary Triangulation System of the United States; its Extent and Uses: WILLIAM BOWIE, U. S. Coast and Geodetic Survey.

This paper shows that extended areas can not be accurately controlled by a number of disconnected local trigonometric surveys, owing to the deflection of the vertical (or the station error) at the astronomic stations which control the positions of the several schemes of triangulation. The primary triangulation, on the other hand, is continuous and no discrepancies will be shown between detailed surveys based upon it. The positions of objects shown on maps, charts and surveys based on the U. S. Standard datum will probably never be changed. Examples are cited of the use of trigonometric surveys by the United States and Canada Boundary Survey, by the state of Maryland in its oyster survey, by the Isthmian Canal Commission, by the city of New York and by the

Clinchfield Coal Corporation in Tennessee. It is planned to extend the primary triangulation into new areas as readily as possible, and it is hoped that, eventually, no place in the United States will be more than 150 miles from some primary station.

Curved Line Vernier Method: H. E. WETHERILL, Philadelphia. Read by title.

Differentiation of Saturated Vapor Engines: J. E. SIEBEL, Chicago. Read by title.

PAPERS ON THE WORK OF THE BUREAU OF MINES
In Relation to Gas Producers and Internal Combustion Engines: R. H. FERNALD, Case School of Applied Science.

The investigations show that practically every shipment of fuel tested in the gas producers, including coals as high as 44 per cent. ash, and lignites and peats high in moisture, has been successfully converted into producer gas which has been used in operating gas engines. It has been estimated that on an average there was developed from each coal tested in the gas producer plant two and a half times the power developed when used in the ordinary steam-boiler plant, and that such relative efficiencies will probably hold good for the average plant of moderate power capacity, though this ratio may be reduced in large steam plants of the most modern type. It was found that the low-grade lignite of North Dakota developed as much power when converted into producer gas as did the best West Virginia bituminous coals when utilized under the steam boiler; and in this way lignite beds underlying from 20,000,000 to 30,000,000 acres of public lands, supposed to have little or no commercial value, through these investigations have been shown to have a large value for power development and the money value of the government's own property has been increased to the extent of probably \$300,000,000 or more. The investigations into the waste of coal in mining have shown the enormous extent of this waste, aggregating from probably 200,000,000 to 300,000,000 tons yearly, of which at least one half might be saved. It is being demonstrated that the low-grade coals high in sulphur and ash now being left underground can be used economically in the gas producer for power and light and should, therefore, be mined at the same time that the high-grade coal is being removed. The use of these low-grade fuels, which have previously been regarded as of little or no value, increases our fuel resources approximately (on the basis of present marketable grades): low-grade bituminous and anthracite, 75-100 per cent.; sub-bituminous, lig-

nite and peat, 60 per cent; or roughly, total increase of 150 per cent. over our present supply of marketable grades of fuel. The logical conclusion from a careful study of the producer gas power situation is that the time is not distant when financial interests in power production will be directed toward the centralization of the producer-gas power plant at the mines and the distribution of the energy developed either by high-voltage long-distance electrical transmission or by pipe systems for conveying the gas.

Investigations in Relation to Fuels and Fuel Efficiencies: O. P. HOOD and S. B. FLAGG, Bureau of Mines.

The Bureau of Mines is engaged in investigating the general problem of the conservation of our mineral fuels by careful study of the problems of preventing waste in mining transportation and storage and of increasing the efficiency with which the fuel is finally used for heat, power, etc., and also the problem of utilization of inferior fuels not now generally used, owing to ignorance as to their value and the means of making that value available. The study of the problem of combustion for steam and for gas engines was inaugurated on a large scale in 1904, and is still in progress. At present the combustion of fuel for steam purposes is being examined in a specially constructed furnace permitting of the determination of temperatures and chemical composition at short intervals between the fire and the stack, and the values of refuse collecting at mines and in yards, and of lignite, peat and miscellaneous wastes from various industries, as fuels for the producer gas engine are being carefully investigated. Also the advantages of briquetting for rapidly deteriorating fuels, the best methods of transportation and storage, the prevention of mine explosions, spontaneous combustion and smoke are receiving careful attention. The purchase of fuel on the basis of specifications covering heat value and composition with penalty and premium provisions has been materially advanced by the bureau. The investigations of the bureau have been favorably received and the results in application by fuel producers and users have been gratifying and encouraging to further work.

With Special Relation to Safety in Mining, Quarrying and Metallurgical Operations: J. A. HOLMES, Director, Bureau of Mines.

The main purpose of the bureau is to increase health and safety in the mineral industries. It is endeavoring to collect statistics relating to acci-

dents and health conditions in and about mines, quarries and metallurgical plants, and is investigating the causes of accidents and the conditions inimical to health and safety. One of the most important investigations is that of the cause of mine explosions, which involves a study of mine gases and coal dust and the conditions under which inflammable gases and dusts may be ignited. A related investigation, that of explosives used in coal mining, was undertaken to determine what explosives are least likely to ignite gases or coal dust. Another investigation deals with the prevention of accidents from electrical equipment in mines. The miscellaneous accidents in mines, including falls of roof, are also being investigated. These miscellaneous accidents, though individually small, each year kill more miners than the great explosions. The mine-rescue and first-aid work of the bureau has attracted more attention than its investigations. The bureau now has six mine-rescue stations and seven mine-rescue or mine-safety cars in the more important coal fields of the country. The work of these stations and cars is largely educational, training miners in mine-rescue and first-aid methods and demonstrating equipment and appliances. More cars and more equipment are needed. It is expected that within a few years the bureau will have trained 20,000 miners, who will be organized into local mine-rescue and first-aid corps, to be supported without aid from the federal government. The success of the bureau's work in behalf of safety will depend on how far this work receives the cooperation of mine owners and miners. The federal government can conduct investigations, the states can embody the results of these investigations in laws, but the cooperation of mine owner and miner are essential to success. The progress in lessening accidents is slow and there is serious need for extending the work of the bureau. Its investigations hitherto largely confined to the health and safety problems about coal mines, should cover similar problems at metal mines, quarries and metallurgical plants.

PAPERS ON AERONAUTICS AND AERIAL ENGINEERING

Holes in the Air: W. J. HUMPHREYS, U. S. Weather Bureau.

Aeronauts have adopted the picturesque phrase, "holes in the air," to describe that condition of the atmosphere that makes uniform horizontal flight impossible, and causes great danger to the aviator. Among the atmospheric conditions that may cause a greater or less drop of the aeroplane

are (a) horizontal strata moving with different velocities, (b) columns of air with different vertical components. The boundary between such strata and columns often is quite narrow, and hence the aviator may pass with disconcerting abruptness from one to the other. On certain conditions the downward acceleration may be even in excess of that due to gravitation and thus the aviator thrown out of his seat.

Aeronautical Screw Propellers: SPENCER HEATH, Washington.

The author discussed the propeller as a transmitter of power, the losses of efficiency due to slip and skin friction. He explained the design of the propeller on the principle that each section is an aerofoil traversing a helical path and deduced the formulae for slip, pitch, thrust, speed and lost power, with applications to two specific cases. The paper was illustrated with numerous diagrams and full-size propeller blades.

Revolving Cylinder Aerial Motor: EMIL BERLINER, Washington.

Under this title, the speaker described the principle of design and construction of a new type of gasoline engine for propelling aircraft. This is made in two sizes and so designed and built as to give considerable power and good running balance.

Work of the Signal Corps in Aeronautics: G. O. SQUIER, Signal Corps, U. S. A.

The speaker gave a description of the work which has been done by the signal corps of the U. S. Army in the study of the prospects of the aeroplane for reconnaissance and dispatch work. A training school for members of the signal corps is established and a number of recruits are enrolled.

Endowment, Organisation and Equipment of Aerodynamic Laboratories: A. F. ZAHM, Washington.

Definition, functions, scope of aeronautic and aerodynamic laboratories. Bearing on the development of aeronautic science, art and industry. Endowment, organization and equipment of the Institut Aerodynamique de Koutchino, of the Aerodynamical Laboratory of the University of Göttingen, the Institute Perotechnique de St. Cyr, Eiffel's Aerodynamic Laboratory, etc. Methods of experimentation and results obtained in various laboratories. Aero Club of America's movement to secure the endowment of a national aeronautic laboratory.

Aerial Engineering: A. LAWRENCE ROTCH, Blue Hill Observatory.

Vice-presidential address, published *verbatim* in SCIENCE, January 12, 1912.

PAPERS ON ROAD AND HIGHWAY ENGINEERING
History of Washington Bituminous Concrete Pavements: MARTIN BROOKE, Washington.

Bituminous concrete pavement was first laid in Washington in 1871, since which date over a million square yards have been laid. Eight hundred thousand square yards are still in existence, less than two hundred thousand yards of which are in the original form. Between 1871 and 1878 half a dozen different types of patented bituminous concrete pavements were laid, a considerable portion of which were unsatisfactory and required resurfacing within a few years. The best of them, however, were fairly durable and economical, and some have continued in use to this day. These pavements were characterized by their thickness and density and by the quality and amount of the tar and tar-asphalt binder used. Bituminous concrete was abandoned in 1878 for sheet asphalt on hydraulic cement base, until 1888, when the inability to obtain bids for the latter type within the legal limit of two dollars per square yard set by Congress compelled the reintroduction of bituminous concrete. The pavements of this character laid between 1888 and 1893 under District of Columbia specifications were cheaper pavements than the old type, and the tar distillate binder used was decidedly inferior to the old tar. Since 1909, a bituminous macadam has been laid in suburban streets, which is very similar to the bituminous concrete pavement laid in the seventies.
History of Tar Concrete Pavements in Ontario: W. A. McLEAN, Toronto.

The first tar-concrete pavement in Ontario (Canada) was laid in Hamilton in 1880, a part of which is still in use. During the years 1889-1906 numerous tar-macadam pavements were laid in seven cities of the province, aggregating about 25 miles. Except in the city of Guelph, the use of commercial coal tar has been displaced by refined tar or other proprietary bitumens. The general experience was that for the first three years the surface has been satisfactory; in five years the surface coat, if not renewed, was worn away in spots; at the end of ten years the surface was generally rough and disintegrated, but still protected the foundation. In Hamilton and Toronto the tar macadam after five or ten years has been protected by a wearing surface of sheet asphalt, from one to two inches in thickness. Experience has indicated that tar of uniform quality and of composition within certain range of proportions, while susceptible to extremes of temperature, is not debarred by climatic or other conditions, as

a useful road material; that best results require a dense mixture, preferably proportioning the aggregate for maximum density; that some doubt may be attached to the complete durability of bituminous surfaces made by the penetration process, and suggesting that the grading of stone in this method, rather than having a uniform size, is desirable; that a moderately coarse aggregate should be brought to the surface, to overcome slipperiness and take up wear; that tar-concrete is less durable under concentrated wear than is sheet asphalt; that broken stone will provide a more stable structure than will water-rounded gravel when bonded by tar; that a paint and grit coat is necessary as a preservative as frequently as signs of surface wear or oxidation appear.

Surface Treatment of Park Roads: SPENCER CROSBY, Washington.

In building and rebuilding park roads in Washington in the last few years a heavy oil or tar binder, applied by the penetration method, has been used with most satisfactory results. For the surface treatment of existing macadam roads, emulsions, waste sulphite liquors, coal gas and water gas tars, and asphaltic oils have been experimented with and last have been found to give best results. One application per year is sufficient to keep the surface in excellent condition. During the last fiscal year 166,000 square yards of park roads were given surface application of oil or tar at an average cost of 2½ cents per square yard, not including cost of screenings. This compares with an average cost of 3.2 cents per square yard for watering in previous years.

Oyster Shell Roads: W. W. CROSBY, Johns Hopkins University.

General remarks on arguments for and limits to use of shells for road purposes. Descriptions of results in Maryland. Particular points to be observed in construction and specifications recommended. Use of bituminous material in connection with shells. Costs of construction and of treatment with bitumen. (Six photographs showing shell roads treated and untreated.)

Changes in Pitch under Exposure and Traffic: W. W. CROSBY.

Description of construction and analysis of tar used. Description of traffic conditions and record of traffic census. Description of results apparent. Analysis of tar surface after three years of use and of tar extracted from samples of this surface. Conclusions as to changes in tar that have apparently occurred.

The Chemistry of Modern Highway Engineering: PREVOST HUBBARD, Institute for Industrial Research.

The necessity of chemical training for modern highway engineers is discussed at some length, and an outline is given of what the author believes to be the essentials of such training. Columbia University has already made the chemistry of road materials a part of its new post-graduate course in highway engineering. It is believed that this training will establish closer relations between the highway engineer and the chemist. Modern conditions demand the work of specialists in highway construction as in many other branches of engineering, and it is not reasonable to expect that the man whose training has been primarily developed along engineering lines can satisfactorily apply the principles of other highly specialized subjects to his work without the assistance of those who have specialized in such subjects. Therefore, the highway engineer should not attempt the chemical testing of road materials, but should cooperate with the chemist in this matter.

A Review of the Use of Bituminous Materials in the Construction and Maintenance of American Highways during 1911: A. H. BLANCHARD, Columbia University.

The following table shows the characteristic developments in the use of bituminous materials during the years 1908, 1909, 1910 and 1911 under the supervision of the highway departments of Maine, New Hampshire, Massachusetts, Rhode Island, New York, New Jersey, Pennsylvania and Maryland. The quantities are square yards.

SURFACE TREATMENT OF ROADS

Tars and Tar-Asphalt Compounds	Fluxed Native Asphalts Oil Asphalts and Residual Asphaltic and Semi-asphaltic Oils	Light Oils
1908. 57,700	1908. 239,500	1908.
1909. 95,500	1909. 910,600	1909. 4,125,900
1910. 123,400	1910. 2,434,200	1910. 9,890,400
1911. 433,000	1911. 7,980,000	1911. 3,765,000

BITUMINOUS PAVEMENTS CONSTRUCTED BY PENETRATION METHODS

Tars and Tar-Asphalt Compounds	Fluxed Native Asphalts Oil Asphalts and Residual Asphaltic and Semi-asphaltic Oils	Light Oils
1908. . 37,800	1908. . 25,200	1908.
1909. 170,200	1909. 2,077,400	1909.
1910. 339,300	1910. 4,840,200	1910. 26,500
1911. 122,000	1911. 8,600,000	1911.

**BITUMINOUS PAVEMENTS CONSTRUCTED BY
MIXING METHODS**

Tars and Tar-Asphalt Compounds	Fluxed Native Asphalts Oil Asphalts and Residual Asphaltic and Semi-asphaltic Oils	Light Oils
1908.. 52,100	1908.. 4,400	1908.....
1909..136,000	1909..219,500	1909.....
1910..158,000	1910..432,600	1910.....
1911.. 24,350	1911..508,100	1911.....

The most important developments during 1911 were as follows: the increased use of the mixing method of constructing bituminous concrete pavements due to the introduction of economical and efficient mixing plants and less fear of injunction and law suits brought by patentees; the manufacture of many types of gravity and pressure distributors for use in the construction and maintenance of bituminous surfaces and bituminous pavements built by penetration methods; the demand by many engineers for bituminous materials for bituminous surfaces which will set up in from 24 to 48 hours; increase in recording scientific data such as recommended by the special committee on the Use of Bituminous Materials of the American Society of Civil Engineers.

Organisation of a Highways Maintenance Bureau of a Municipality: W. H. CONNELL, New York City.

It is, in the writer's opinion, desirable in the organization of a Highways-Maintenance Bureau to follow the theory of centralization of control. First comes the planning of an organization adapted to the needs of the municipality, then the proper control of the same, which can only be accomplished through the appointment of men especially qualified to supervise the work of the various branches of the organization. The responsibility of course should be centered in one man, and he should be familiar with the social conditions of the municipality and keep in close touch with the activities of the divisions under his control. All work should be initiated through job orders and unit cost records kept of the same. All street repairs, etc., should be done by the highways-maintenance force. All repairs to pavements between railway tracks over corporation cuts, etc., should be done through and under the supervision of the Highways-Maintenance Bureau. This procedure centralizes the responsibility and control of work coming under the jurisdiction of said bureau.

Utilisation of Motor Truck Trains in the Maintenance of Truck Highways: L. W. PAGE, Office of Public Roads.

The object to be accomplished is the development of an automobile equipment which will include all the apparatus and facilities necessary to efficiently employ a repair gang of eight men in the maintenance of road surface over one hundred miles of roadway or more as the working conditions will permit. This purpose as set forth has three significant implications: First, that the cost of the equipment should be kept consistently low or within the range of customary expenditures in this direction; second, novel or especially manufactured apparatus should be avoided so that the equivalent apparatus can be secured in any locality, and, further, that existing investment in similar details of equipment can be made use of; third, that the outfit should be so flexible in its makeup as to readily serve a variety of utility or lend itself to peculiar requirements under varying conditions. In performing service in road repairing, the machine should incorporate as many of the requirements of a portable power plant as possible, such as hoisting, pumping, and, where necessary, air compression and power-shaft driving. The automobile chassis selected for recommendation is the 5-ton gas-electric type manufactured by the Couple-Gear Freight Wheel Company, Grand Rapids, Michigan. This chassis is fitted with a Sprague electric hoist, which can be used for a variety of purposes. The motor of this hoist is directly connected to a rotary pump which can be used to furnish bituminous material from a tank carried on the machine through a distributing device permanently attached to the rear of the chassis. An electric air compressor and a power sweeper could also be attached to the machine. The chassis can be fitted with a removable platform body, with or without stakes or side racks; and it may also be fitted with a steel dumping body, the forward half of this body to be fitted with removable partitions to provide spaces of one or two cubic yards capacity for carrying different sizes of road material. The rear half of the body may be used for carrying the bituminous heating tank. Seats for four men and spaces for tools are provided between the dumping body and the driver's seat. The latter is made wide enough to carry three men beside the driver. It would be impossible to use standard wagons as trailers for carrying material, and a sprinkling wagon or bituminous tank mounted on its own wheels could also be carried behind the tractor. It would prob-

ably be necessary to establish supply stations at intervals along the road to be maintained with this equipment.

Underground Pipe Construction in Streets: C. E. BOLLING, Richmond, Va.

Much money could be saved in street construction and maintenance if pipe systems, such as for water, gas, sewer, etc., were laid before the surface of the roadway was constructed. All main pipes should be placed and connecting pipes laid to each lot, whether the latter are occupied or vacant. The estimated annual cost on such connections, assuming a 4 per cent. interest on the outlay, is 96 cents. The rapid rate of growth of communities so improved is marked. The increased value of abutting property, due to the conveniences obtained, creates tax receipts generally in excess of this annual interest. The cost of making pipe connections through improved roadways is at least 60 per cent. greater than through unimproved ones, and the cost of restoring and maintaining the pavement is doubled.

Impact Testing Machine for Pitch: W. H. FULWEILER, Philadelphia.

This apparatus was designed to determine the relative binding qualities of bituminous materials used in road construction and maintenance. The material to be tested is enclosed as a thin film between two steel dies. The dies are designed to avoid the effect of suction. An excessive breaking load is applied by the impact of a falling weight, and the resistance to rupture of the film is recorded by a spring balance provided with a maximum indication hand. This form of apparatus may be used to compare the binding qualities of any grade of material. In a modification of this apparatus a pendulum in falling separates the dies, and automatically records the energy absorbed. The results obtained have not yet been completely analyzed, but apparently they will serve to differentiate classes of materials and indicate the most effective viscosity of any material for road use.

Centrifugal Method for the Determination of Free Carbon: W. H. FULWEILER.

This method was designed to afford rapid and reasonably accurate results to obviate the danger of handling carbon bisulphide in the laboratory. The material is weighed with a stoppered Goetz phosphorus tube dissolved in CS_2 with shaking and centrifuged until the precipitate ceases to contract. The percentage may then be read off directly. The tubes are calibrated for the particular class of material to be tested by reference to standard

samples. Care must be taken to keep the tubes scrupulously clean. The lower the percentage of free carbon the closer this method checks with the ordinary gravimetric method. In this method the carbon bisulphide is not exposed to the air and considerably smaller quantities are required.

Cost of Road Building with Convict Labor: J. H. PRATT, Chapel Hill, N. C.

The author has not submitted abstract.

The following papers in this group were read by title in the absence of authors and manuscripts:

Street Asphalt Paving Mixtures, and Value of Blown Asphalts and their Manipulation: H. B. PULLAR, Chicago.

Organisation of the Engineering Department of Coleman du Pont Road, Inc.: F. M. WILLIAMS, Delaware.

Organisation of Convict Labor on the Virginia State Highways: P. ST. J. WILSON, Richmond, Va.

Some Limitations of Distributing Machines: H. B. DROWNE, Columbia University

Voids in the Aggregates of Bituminous Concrete Pavements: A. H. BLANCHARD, E. R. DONLE and C. M. HATHAWAY, Columbia University.

It is expected that the papers of this group will be published in book form at an early date.

G. W. BISSELL,
Secretary

SOCIETIES AND ACADEMIES

THE HELMINTHOLOGICAL SOCIETY OF WASHINGTON

THE seventh regular meeting of the society was held at Dr. Ransom's residence on December 19, 1911, Dr. Ransom acting as host and Mr. Crawley as chairman.

Dr. Pfender presented a brief note on the desirability of zoologists and medical men using *Treponema* rather than *Spirochæta* for the organism causing syphilis.

Mr. Foster presented the following note:

Analysis of the Results of 87 Fecal Examinations of Sheep Dogs for Evidences of Parasitism.

Order No. 176 of the Bureau of Animal Industry requires that all collie or sheep dogs imported to this country shall be held in quarantine pending the result of a fecal examination to determine the presence or absence of the gid tapeworm. As it is difficult to distinguish the eggs of the gid tapeworm from those of other less injurious species, all dogs found infested with tapeworms are given a suitable tæniacide.

Since November 25, 1910, when this order went

into effect, the feces of 87 dogs have been examined. Of these, 50 dogs, or about 57 per cent., were infested with parasitic worms. Of the 50 dogs thus parasitized, 28 were infested with nematodes only, while 22, or about one fourth of the dogs examined, were infested with tapeworms, either of one species only, of two or more species, or of tapeworms and nematodes.

Of the 22 dogs infested with tapeworms, there were

- 7 infestations with *Tænia hydatigena*,
- 8 infestations with *Tænia pisiformis*,
- 4 infestations with *Dipylidium caninum*,
- 2 infestations with *Multiceps serialis*,
- 8 infestations with unidentified *Tænia*.

This is a total of 29 infestations with tapeworms, representing four recognized species. The number of infestations is of course greater than the number of dogs infested, since in several cases one dog proved to be the host of two or more species.

The heaviest infestation recorded, from 14 to 19 specimens of tapeworms, representing three species, was as follows:

	Specimens
<i>Tænia hydatigena</i>	6
<i>Tænia pisiformis</i>	3
<i>Dipylidium caninum</i>	5-10

It will be seen from the foregoing that *T. hydatigena* is the tapeworm which was most frequently found. Out of 37 identified specimens, this species occurred 13 times, 35 per cent. of the specimens identified being of this species. *D. caninum*, although found in but 4 infestations, comes next in number of specimens found, i. e., 12. There were 8 infestations with *T. pisiformis*, with a total of 10 specimens, while only 2 specimens of *M. serialis* were found and in both cases the identification is uncertain.

Of the 87 dogs examined,

- 9.2% were infested with unidentified tapeworms,
- 9.2% were infested with *Tænia pisiformis*,
- 8.1% were infested with *Tænia hydatigena*,
- 4.5% were infested with *Dipylidium caninum*,
- 2.8% were infested with *Multiceps serialis*.

It is interesting to note what a small per cent. were infested with *D. caninum*, which is usually considered the commonest dog tapeworm. In all the species considered in this paper, the percentage of infestation is far lower than the average given in the comparative table of Stiles, 1898 ("Inspection of Meat for Animal Parasites," p. 105). The writer is inclined to think that the small percentage shown in the examination of imported dogs

is the result of the greater care bestowed on valuable animals such as these are.

Mr. Leonard read a paper entitled "Some Abstracts from Investigations on Parasitic Diseases Carried on at the Marine Hospital, Wilmington, N. C." The paper showed the percentage of infection of man with various intestinal parasites as determined by 688 microscopic examinations.

Mr. Hall presented the following note:

Notes on the Parasite Fauna of Colorado.

The writer has recently compiled a list of the parasites of animals in the state of Colorado, the list covering published records, material in the collections of the Bureau of Animal Industry, the National Museum, the Hygienic Laboratory, the Naval Medical School, and some records furnished by workers in various colleges. Most of the Bureau of Animal Industry specimens from Colorado were collected by the writer during the past summer.

Using the word *identified* to indicate at least a generic identification, the list includes at present a total of 251 identified and 27 unidentified species of protozoan, trematode, cestode, nematode, crustacean, mallophagan, hemipterous, dipterous, siphonapteran, arachnid and annelid parasites.

Among the interesting and apparently new species collected by the writer during 1911 may be mentioned a *Rictularia* and a *Tænia* resembling *T. pisiformis* from *Canis nebracensis*, and a *Chabertia* from *Thomomys fessor*.

One case of hookworm found by Dr. Webb, of Colorado Springs, in a patient from the south is of interest in that it suggests that with carriers of hookworms entering the state, the disease is likely to get a foothold, especially in southern Colorado. In fact, it is likely that an examination of the Mexican miners in southern Colorado, where the climate and the mode of life in the Mexican section of some mining towns is favorable to hookworm development, would be repaid by positive findings.

The collection of a species of *Anopheles* by G. P. Weldon in Delta County is of interest, as this is the first record of this genus from Colorado, according to Professor Gillette, who furnished the writer with the record. In his opinion, we have here the explanation of an outbreak of malaria on the western slope of Colorado.

The occurrence of what Stiles calls *Dermacentor andersoni* and Banks calls *D. venustus* has been reported from ten counties in Colorado by Hunter and Bishopp (1911). It was first reported from Colorado by Banks (1895), under the name of

Dermacentor americanus. As the carrier of Rocky Mountain spotted fever, this tick is of especial interest at present.

Dr. Ransom presented some figures illustrating the life history of *Habronema muscae* and showing stages in the fly and in the horse. A note on this life history has already been published in SCIENCE.

Dr. Ransom presented the following note:

The Occurrence of Cheilospirocha hamulosa in the United States.

The nematode *Cheilospirocha hamulosa* is parasitic in the gizzard of the chicken. A record of the occurrence of this species in the United States has apparently not been published heretofore. The helminthological collection of the Bureau of Animal Industry contains specimens collected in Kansas in 1897, identified by Stiles and Hassall; in New Jersey in 1903, identified by Ransom; in Hawaii in 1907, identified by Hall and Hassall; in the District of Columbia in 1908 and 1909, identified by Hall; in Ohio in 1911, identified by Graybill, and in Indiana in 1911, identified by Ransom.

Dr. Pfender presented the following note:

Symptoms Accompanying an Infection with Taenia saginata.

Recently one of the writer's patients, a woman 54 years old, presented herself for treatment and complained of the following symptoms: itching all over the body, skin eruptions, recent trouble with cold feet, twitching of lower limbs, nausea, no desire for food, excessive bloating, flatulency, occasional dizziness and excessive leucorrhoea. She complained that pieces of worm, from 3 to 30 at a time, were being constantly passed. On treatment with oleoresin of male fern the worm was passed. Since then the nervous and digestive symptoms have entirely disappeared and the general health is improving.

THE eighth regular meeting of the society was held in the rooms of the Zoology Division of the Marine Hospital Service, January 11, 1912, Dr. Stiles acting as host and Mr. Foster as chairman.

Dr. Garrison exhibited a specimen of pancreas sent in by Assistant Surgeon Kerr, U.S.N., from Guam. The pancreas had a specimen of *Ascaris lumbricoides* in the duct of Wirsung, extending from the intestinal termination of the duct clear across the pancreas, the head being near the periphery. He also showed two appendices, containing 2 and 3 specimens of the same worm, sent in by Dr. Kerr from the same place.

Dr. Ransom presented pictures of a worm sent

in by Dr. Darling from the Canal Zone and said to have been collected from the urine of man. The worm is a specimen of *Mononchus*, a free-living genus, and the case is therefore one of pseudo-parasitism. The tooth in the buccal capsule would suggest a true parasite to most observers.

Dr. Ransom noted that numerous cases of *Cysticercus bovis* had recently been detected in abattoir inspection, 15 cases having been found in two days at Omaha. The parasite has also been rather common at Chicago, Kansas City, Milwaukee, Buffalo, etc. Up to a year ago, more specimens of *Cysticercus cellulosae* had been found than of *C. bovis*, due probably to the fact that the former were more carefully looked for.

Dr. Stiles noted that Dr. Francis had recently sent him several cases of *C. cellulosae* from Texas with the statement that this parasite was not uncommon in Texas.

Dr. Stiles presented a note on the preliminary survey of Texas for hookworm. He spent one month there, working at the state university, the normal school and the schools for the blind and the deaf and dumb, and in the open country. He demonstrated hookworm by microscopic findings in 45 counties and saw undoubted physical cases in another county. The disease occurs chiefly in the eastern portion of the state, and is probably unimportant in the northwest portion. In the rural eastern part, some places show about one third of the people infected. There are some severe cases, but none as bad as the worst cases in Alabama and Mississippi. A preliminary survey of the coal-mining part of West Virginia was interrupted after the hookworm had been microscopically determined in nine localities.

The rest of the evening was devoted to a talk by Dr. Stiles on "Foreign Parasitologists and Their Work."

THE ninth regular meeting of the society was held in the rooms of the Zoology Division of the Marine Hospital Service, 25th and E Streets, N.W., February 16, 1912, the president, Dr. Stiles, acting as host and chairman.

Dr. Stiles presented a number of generic names of parasites of man for consideration by the society. The society agreed to recommend to the International Committee on Nomenclature and to the Committee on Medical Zoology for adoption according to the plan agreed upon at the last Zoological Convention at Gratz, the following names:

Cestoda: *Davainea*, *Diplogonoporus*, *Dipylidium*, *Echinococcus*, *Tenia*.

Nematoda: *Ancylostoma*, *Ascaris*, *Draconculus*, *Gnathostoma*, *Necator*, *Strongyloides*, *Trichostrongylus*.

Acanthecephala: *Gigantorhynchus*.

Gordiacae: *Gordius*, *Paragordius*.

Dr. Stiles presented a report on the work of the Rockefeller Hookworm Commission, and in this connection noted the compilation of the nomenclature used throughout the world in connection with hookworm disease. He also noted that the name *Necator africanus* given by Looss to a hookworm from the chimpanzee was preoccupied and that he had written to Looss asking him to change it.

Dr. Stiles also presented the outline of a symposium on amebiasis, which is to be part of the program at the coming International Congress of Hygiene and Demography.

Mr. Hall presented the following note:

A Second Case of Multiceps multiceps in the Coyote.

At the meeting of the society in April, 1911, the writer presented a note on a case of *Multiceps multiceps* in the coyote, *Canis nebrascensis*. This was a case of infection by artificial feeding with *œnurus*, the coyote dying six days later of septicæmia. Fifty-two heads of *M. multiceps* were recovered from the intestine. I wish to record a similar case from a coyote in the same litter, fed at the same time. Death occurred 14 days after feeding, and in the writer's absence the post-mortem was made by Dr. Graybill, who found 4 heads of *M. multiceps* in the intestine. A comparison of these heads with the 52 recovered from the first coyote shows that apparently they had not developed any more in 14 days than in 6 days. In this connection may be mentioned a note presented before the society at the meeting in January, 1911, in which a case was noted where a dog fed *œnurus* 82 days previously was found on postmortem to have 5 tapeworms, the largest having eggs with undeveloped onchospheres and the smallest being less than one half inch in length.

These data indicate that this worm may at times develop very slowly. Leuckart (1886) has noted that of three dogs fed *œnurus*, one was found to have over 100 completely developed tapeworms in about ten days; another had only heads of tapeworms after three weeks, with bands of segments an inch long attached to them in a few cases only, while the third failed to develop any tapeworms.

The remainder of the evening was devoted to a

discussion of the nomenclature of parasitic diseases.

MAURICE C. HALL,
Secretary

THE ACADEMY OF SCIENCE OF ST. LOUIS

THE meeting of the Academy of Science of St. Louis was held at the Academy Building, Monday, February 19, 1912, at 8 P.M., President Engler in the chair.

Dr. Charles H. Turner presented a paper on "Experimental Study of Color Vision and Pattern Vision of Bees." The conclusion reached by experiments was that bees can distinguish, not only between colors, but also between color-patterns, and that this behavior is of value to them in recognizing plants that contain an abundant supply of honey. Hence, since bees can distinguish colors and the fine details of color-pattern, there is nothing about the visual powers of bees that militates against the theory that the colors and the color-patterns of flowers are adaptations to insect visitors. The bees respond to these colors, not because they prefer one color to another; but, because, under certain conditions the color or color-pattern selected has acquired a utilitarian meaning—has come to be the sign of something worth a response.

Although Plateau's conclusions do not harmonize with the above statement, yet the actual facts observed by him are in perfect accord.

Dr. H. M. Welpley spoke on "Miniature Indian Baskets" and exhibited two specimens made by the Pomo Indians which were viewed by means of simple microscopes. The foundation of the baskets is from the white leaf willow (*Salix argyrophylla*) and is sewed with California sedge (*Carex barbara*). The baskets are made in pattern black and white, the black being from the root of the California sedge. The larger basket is .18 × .10 inch, with the opening .06 inch across, and weighs one fourth grain. The smaller basket is .10 × .04 inch, with an opening .04 of an inch across, and weighs one twentieth grain. Both baskets are woven in the same manner as large baskets and carefully patterned. The Pomo Indians, located in northern central California, are noted for their basketry, which is unrivaled in North America, for workmanship, beauty and variety of designs. The women are the weavers, but the smaller basket was made by a man who is one of the few men weavers among the Pomo Indians.

THE PRESENT EDUCATIONAL SYSTEM AND THE TRAINING OF ECONOMIC ENTOMOLOGISTS¹

AT the beginning, I wish to call your attention to the fact that this paper deals with a system and its relation to the preparation of a class of men to meet certain insistent economic conditions brought about by a twentieth-century civilization. I do not wish to place the instructor in any other position than that of a more or less willing or unwilling agent of this system, or the university graduate in any other light than that of the inevitable result of the workings of that system.

The world of to-day demands the carrying out of certain undertakings, the doing of certain difficult things, which, in turn, demands certain qualifications in the men who are to do them, and demands them as never before in the world's history. These men must be taken as lads and so trained as to meet these imperative demands. Where can the American boy get this preparation that these existing conditions demand? Who has the ability, willingness and the freedom to train him therefor? If I were the only one asking these questions, or were the science of entomology alone involved, there would be grounds for suspecting that there was something wrong with the entomologists. But this is not the situation.

Several years ago Mr. F. W. Taylor, who is not only not a man with a grouch, but one of the foremost engineers in the country, stated that he had long ago made up

¹ Read before the Washington, D. C., meeting of the Entomological Society of America, December 27, 1911.

his mind not to employ another college graduate unless the latter had either worked outside in a shop for two years or else had been forced out of school and into practical work. Not only this, but Mr. Taylor goes on to say that the overwhelming majority of employers of this country want nothing to do with college graduates, if they can help themselves, until after they have been tried out, so to speak, outside the university.

More recently Mr. R. T. Crane,² a Chicago manufacturer, of nearly sixty years' experience with, as he tells us, all classes of men, is even more dissatisfied with the output of our colleges and universities and is much inclined to, unjustly, throw overboard all technical training, although evidently fully recognizing the importance of the practical application of science.

The self-educated or self-made man must, almost of necessity, possess an iron will, preferring to override obstacles that obstruct his way, rather than to evade them. He is, on the whole, more liable to become dogmatic, thus going to extremes, and to permit prejudices to obscure reason, than is his fellow with a technical training.

Railway people who are on the watch for men of action tell me that they like the university man with the technical training, provided he will have devoted his vacations to their temporary employment, thus carrying the theoretical and practical features along together.

The foremost electrical concern in this country, the Westinghouse, also likes to get college and university men, but is mighty careful not to let them get where they can do any damage, until they have given them a training in their own practical school.

Now it is not to be supposed that the instructor in entomology will be given advantage over his colleague, the instructor

in engineering, or that his students will be allowed to follow a special educational system of his own. Indeed, he is lucky if he is able to secure even equal privileges and facilities for carrying on his work. It can not, therefore, be supposed that graduates in entomology will be any better qualified than those in other courses, and I am sorry to say they are not.

During the last twenty years, including the present, I have had with me between forty and fifty assistants, nearly all college and university graduates, and I tell you candidly I would not take another one fresh from school and with no further training, were I not obliged to do so. Indeed this is true in general. All like college and university trained men, but after they have been made over elsewhere. Now, what is the matter?

The most of those who gave university instruction to the men who afterwards worked under me are here before me, and I fully believe that, had I been placed in your position, I probably could not have done better, perhaps not as well. Besides, the university graduate is not suffering from too little instruction, but from too much of it. He has had anywhere from fourteen to eighteen years of continuous, miscellaneous instruction and instead of his mind being clear and penetrating, it is more apt to be clouded and befuddled. As Bacon puts it, "The education of the senses neglected, all after education partakes of a drowsiness, a haziness, an insufficiency which it is impossible to cure." The man fresh from the university classroom is overloaded, not with what he needs but with that which he does not require; he is afflicted with dyspepsia of the brain, or mental indigestion, and until he gets rid of these ailments he is of little use. This is why there is so much aversion to employing them in practical work or investigations.

² Lately deceased.

It requires, as Mr. Taylor has stated, two years of actual outside work before they can be at all profitably employed.

Now, I do not believe that such conditions as these are necessary to a college or university education, but that the cause therefor will be found in the methods employed. If we go back to medieval times and for a considerable period thereafter, we find but scant literature, and that little accessible only to the few. Therefore instruction was of necessity oral and knowledge obtained only at great cost was retained only by committing to memory with the utmost exactness. Thus was an educational system born of necessity and fitted to the conditions existing at that time. A pupil must not only receive instruction exactly as imparted, but must be able to show by examination that he could repeat what he had heard with the same minute exactness, otherwise what he had obtained would be erroneous and, therefore, of no value.

Let us now come back from medieval times to the twentieth century. To an age when ships disabled at sea may make their situation and location known a thousand miles away and receive aid from other vessels within reach, though not within sight; to an age when you can, within a few hours, communicate with your friend, whether he happens to be in Tasmania, Alaska, Capetown or Hong Kong; to an age when, if a married man, you can, seated in your hotel here in Washington, bid your wife good-night, whether she be in Boston, Chicago, St. Louis or New Orleans; when you can board a floating palace in New York and within five days step out of it in England; and when you enter a railway coach in Chicago and in three or four days step out of it in either Portland, Oregon, San Francisco or Los Angeles; or, you can leave Chicago in the same way and in

eighteen hours walk the streets of New York City.

From a time when a serious question arose in the minds of men as to whether or not insects were the results of spontaneous generation, to a time when insects from all quarters of the earth are being transported about from one country to another and reared up in myriads to destroy other insects. Within the memory of some of us, the entomologists of America could be told off on the fingers of one hand, and these were engaged in describing genera and species in a way that to-day is in many instances practically unintelligible. Some years ago, I tried to get, from a man who had grown up from boyhood with Dr. Asa Fitch, some information regarding this one of the fathers of economic entomology. What I did succeed in learning was this: "Fitch was a queer fellow, always prying into things that the Almighty never intended us to know."

Thirty years ago a state entomologist in the middle west resigned his office, telling his friends in confidence that economic entomology had reached its limit, and, so far as he could discern, there would soon be nothing for the entomologist to do. At the close of A.D. 1911 the question is to get men properly trained to carry on the work that state and nation demands to be done. There is hardly a civilized people on the face of the earth among whom there are not to be found officials who are entomologists. Not a year passes by during which some of these may not be seen here in Washington, studying our methods of work, our collections, especially the former. One of America's foremost philanthropists is sufficiently aware of the importance of this to supply the necessary funds to enable these men from other countries to come and see for themselves how the science of entomology is being profitably applied in this

country. Now, these gentlemen from abroad have access to all of our publications; can read of what we do and how we do it. They could probably read up and go before an examiner and get an excellent grading on their replies, yet it is significant that a practical business man should think this insufficient, so much so that he willingly pays the expenses of such men to enable them to get into closer touch and see for themselves how investigations are carried on, the facilities required and the methods employed in their use.

There is another phase of our present-day entomology that, in passing, I wish to note, and that is the great desire among systematists for the examination of types, the desire to see and handle the precise insect that Say, Harris, LeConte, Grote and others, both at home and abroad, had before them when they described a species and gave it a technical name. Men will travel hundreds of miles, and visit foreign lands in order to do this. Now, all of the descriptions of these are in print, all can be committed to memory and a man with ordinary intelligence could go into a classroom and pass a most excellent if not indeed a perfect examination, all that you could possibly require of a student. Does not this of itself show clearly that, whether it be a university student of twenty or thereabout, or an independent student, official or amateur, of thrice that age, he must study the things themselves? You can not make up-to-date entomologists within the walls of a classroom.

Dropping, for the time being, the subject of present conditions in the matter of progress, let us take up the educational system under which the men who are yet to come into action are to be educated.

Coming from an era when oral instruction and memorizing were imperative, through an era when the educated were the

priest, the astrologer, the alchemist and the philosopher, with a few of the nobility, the remainder being illiterate and therefore ignorant and brutal, when that now powerful educator, the public press, was as yet unknown, and the almost equally powerful educator, the public library, was inaccessible to all but the few, this system has come down to our radically different twentieth-century civilization, unfortunately, deplorably intact. Indeed, what was once a necessity has now become sadly perverted. Once, the student must of necessity listen and memorize with exactness what was told him, and pass a most rigid examination. Now, however, the object appears to be to get the student to remember long enough to pass his examination. It is of such that Huxley says: "They work to pass, not to know; and outraged science takes her revenge. They do pass, and they *don't* know." Count Leo Tolstoi years ago wrote that he had become convinced that written or verbal examinations were a relic of medieval scholastic superstition, and that in the present order of things, they are decidedly impossible and only harmful. And, again, Huxley says, in his twenty years' experience as an examiner, from boys and girls of elementary schools to candidates for honors and fellowships, that it was a clear case of familiarity breeding contempt, and his admiration did not wax warmer as he saw more and more of its workings. In his opinion, examination is a good servant but a bad master, and he expressed the fear that it would sooner or later come to be the master.

But, you will ask, what has all of this to do with the entomologist, whom you have hardly mentioned? Practically nothing, gentlemen, for the reason that from the age of six years, when he entered the primary school, until he is eighteen or twenty,

or half way through his university course, he is not supposed to have any idea of what his future is to be—what he is to do in this busy world. And his education has been given with no reference to whether he is to be a doctor, lawyer, engineer or entomologist. He has simply drifted with and been one in the procession. But between his senior year in high school and his entering into the university he must pass an examination. I have just shown the value of this and all other similar examinations in forming an estimate of what he really knows. In Washington, and possibly, though rarely, elsewhere, a pupil is allowed to specialize in the high school. Here in the city we have a technical high school and a business high school which, although they may not be all that is to be desired among even those most responsible for their existence, constitute a movement in the right direction and should be encouraged both here and elsewhere.

When, therefore, on coming from the high school and presenting himself before the university for admission, where for the first time he is offered separate courses from among which he must make a selection, he naturally expects that his efforts will, or ought, to be directed along a line with what is to be his future occupation; what he is to do in future. But he soon finds that while he may select his course, about the same job lot of instruction will be administered as before.

If he has come to the university of his own accord, as is probably the case, he is like a vessel with steam up, ready to put out to sea. It does not need additional force, what it requires is direction—a pilot with a firm hand and who understands his business. Instead of this, however, the applicant will in most, though not all, cases find himself at once placed in a mental strait jacket, and if it does not fit him

the screws will be applied until he fits the jacket. Incisions will be made in his brain and a heterogeneous mass of instruction forced in. If he can stand the strait jacket and hold the instruction in long enough to pass his examinations, he will be allowed to continue and finally be graduated with much ado and a great flourish of trumpets. If he can not withstand this treatment he is sent home in disgrace.

Mr. Taylor tells us that after he had given up all hope of being able to use as engineers the men who had graduated and gone out from the university, but had been obliged to throw them all overboard until they had spent a couple of years outside in practical work, he found that there was a class going out from these institutions that it paid to look over with a view of securing material for successful engineers; and this was the class that honestly flunked and went back home to work. This, to use a western mining expression, was found to be "pay dirt."

As a matter of fact the embryo entomologist, on his first admission into the freshman class, or as soon as he has decided upon such a course, should be informed that he is there to work; to himself do things and that while there will be examinations he is there to study the science of entomology and not the science of passing examinations. In order to enable him to meet these requirements he should be given first that for which there is the greatest need, and thereafter he should be provided with what he needs, when, and not before, his progress requires it, precisely as with any other tool or instrument.

His first requisites will be honesty and good judgment. If he does not already possess these, he had best stay out of entomology, or any other science, for that matter. His mission, if he succeeds, will be to penetrate the unknown and tell his col-

leagues and the world precisely what he has seen. If he can not do this with strict honesty and good judgment his efforts will be worse than useless. Just the extent to which the present system of recitations and examinations tends to develop honesty and common sense I, for one, have never been able to clearly determine.

Having gained admission and taken up his freshman work, his first need will be that of language. As an investigator he will be required to penetrate the unknown and tell in clear unmistakable language what he saw there. In my own division of the Bureau of Entomology there are, or have been, over twenty-five individuals, engaged in certain investigations, whose field notes, including name of observer, locality and date, are finally copied on library cards and filed in the office under the name of the insect to which they refer. No one can tell when the information contained in these records may be required for use, who will make use of it, or where the original observer will be at that time. He may be one, two or three thousand miles away, even in another part of the world. Therefore, his records must be clear, concise, including every detail, but excluding every superfluous word, in order that any other of the division may be able to understand precisely what the observer intended to state. While the capacity for doing all of this should be attained in the freshman year, as a matter of fact if you find more than one out of every ten or fifteen university graduates who can do this you may consider that you have found an exceptional group. This seems to be one of the requisites, not obtainable in a university course, but which must be secured later.

If the student has not already had a couple of years of Latin in the high school he might take it up at once, for the reason that it contains the key to nearly one half

of the English language, while German holds the key to almost all of the other half. Both German and French are especially rich in scientific literature to which he must have easy and intelligent access. In his case, it is not a classical but a practical working knowledge of these languages that is demanded, and if any of these languages are eliminated it should be Latin. With him it is not a text-book, but a business acquaintance with languages, that he requires. He will very early become aware that the German and French scientific literature with which he will come in contact and which he must read in the original and comprehend, is quite different from that of the classroom. He will be obliged to purchase dictionaries and do a lot of self-education that will not be recognized in ordinary examinations. This need not discourage him, however, as, probably, his instructor would have to do the same thing. A professor of Greek in a theological university once told me, on returning from a summer's sojourn in Greece, that he got on very well after he had become familiar with the language. Also, at the outset the student should have elementary entomology, but it should come in the way of elementary zoology with especial reference to insects. Just what text-book is to be used here I shall leave to the instructor in entomology. Those who write text-books in zoology usually know little of insects, and it is perhaps as well that they do not give more about them. The student will need to refer to considerable literature any way, and the library is the best place to be found for keeping text-books; the more they are kept and used there the better. Entomology should be studied during the warm seasons of the year when insects are alive and active, but somehow it happens that when insects are alive the student who should study them in that condition is too

deeply engrossed in the study of dead languages. This leaves only short periods in fall and spring during which it is possible to observe living insects in the woods and fields. These brief periods should be employed to the best advantage and the student should be told, at the end of the first week of the opening term, that a large quantity of material will be required for laboratory work during winter; that the institution does not regularly supply this except for reference purposes; that it is to be found in plenty in fields and woods, where he must himself procure and preserve it for future use. He should be informed that, right then and there, the system of grading, of merits and demerits, that will be in vogue during his university career will be put into operation, and he should be marked on the quantity, condition and proper preservation of this material. The instructor should by all means be able to spend one or two afternoons each week during good weather in the fields and woods with his students. This will encourage and develop their habits of observation and enable them not only to see things, but learn where and how to find insects and properly preserve them. This last faculty appears to be another factor in the education of an entomologist that frequently there has not, in his four years' training, been time to look after. Probably any one who saw the condition of material sent to the bureau or National Museum for determination would get the same impression. As a matter of fact, all of this should be required in the freshman year and the student marked on the quality of his work precisely as if done in the laboratory. He will and indeed must learn by experience that imperfect, dirty and improperly preserved insects are unsatisfactory subjects for study. It is said that an entomological instructor, in a fit of desperation, sent an

unusually dull student to the college collection to find out the number of legs an insect possessed. The poor fellow, after being out for a considerable time, returned and reported that most of them were possessed of from one to five legs, but occasionally one was found with as many as six legs.

Laboratory work means so much and is so far reaching that it is impossible to overdo it. It is here that the instructor gets the closest to his students and all work together almost like colleagues, thus giving him the opportunity of his life to study his pupils and correct their individual defects. Then, there are so many things that enter into laboratory work, on which the instructor can grade students with absolute justice, developing the traits that we who are to use them later on are so anxious to see in them. I would rather have a few days with a man in the laboratory or field than copies of any number or all of his examination papers.

He should be required to make full notes which may be graded both from an entomological and a literary point of view; he should make drawings, both free-hand and otherwise, dissections and descriptions. Besides an endless variety of rearings, breedings and interbreedings can be carried out.

The aim throughout the entire university course should be to eliminate teaching or instruction just as much as possible, and substitute therefor direction, encouragement with insistence upon accuracy and completeness. The only help given a student should be that which affords the greatest aid in enabling him to help himself. Make him work and do it properly. You who are training entomologists are already doing altogether too much teaching. Fully one third of the energy of the university instructor is being thrown away on account

of being misdirected. Not only does the student fail to profit by this, but it is detrimental instead of beneficial.

Just here I wish to interject an innovation which, if carried out, would mean a great deal, not only for the student himself, but for the one into whose hands he will fall after graduation.

Let the student spend all or as much as possible of his vacations in actual field work under competent entomologists. This work should count in credits for graduation and should be based upon efficiency and quality of work done. At present, he must report for duty at his own expense, often long distances away, which, with the limited compensation he could command, would not be profitable. But if his work counted for credits in the university, he might well afford the expense involved.

In his sophomore and junior years the student will require a knowledge of botany, sufficient to enable him to recognize plants and assign them to their proper family, or genera if common. Beyond this, an entomologist had better consult a botanist. He will need some knowledge of chemistry, geology, climatology, physics, comparative zoology, comparative anatomy, morphology and physiology. He must have some training in histology. He need waste no time on higher mathematics. He can get a working knowledge of mensuration, should it become necessary to apply it. He is already being trained in a science having no superior in developing exactness, acumen, and what a knowledge of higher mathematics does not always presuppose, good judgment. Incidentally, let him read Sherlock Holmes carefully and intelligently.

A few years ago a university that could hardly be convicted of underestimating its own greatness, graduated a student in entomology. By dint of hard, practical work

outside during vacation, and in the laboratory, he was fortunately better equipped in entomology than are most graduates; it was not so much a case of graduating first and completing his education afterwards. His trigonometry, however, proved almost too much for him and remained hovering over his head, like the raven of Poe, until the very last, and, even then came very nearly preventing his graduation. He is making good since leaving the university, and has succeeded in forgetting his trigonometry, which cost him so much in both time and energy, but for which he has no more use than he has for navigation; but is still handicapped for the training in histology for which, while in school, he had begged, but was prohibited from obtaining.

In languages, classroom language may well end here, probably with the freshman year, but his training in the contact, absorption, every-day-use kind, will never end. I might say here that the lazy or don't-care fellow has probably found the work uncongenial and dropped out, also during the freshman year. All of the time continue to give laboratory work whenever possible, and outside work, too, if it can possibly be arranged.

At the beginning of the senior year give your student one or more pieces of original work, no matter what so it involves and brings into action all that he has previously acquired; and include embryology, parthenogenesis, polyembryony, or any others belonging to the most advanced entomological work being carried on elsewhere. Direct him, advise him, encourage him, but make him work out his own salvation and learn to take care of himself under any condition or situation. This sort of a man will need no petting or unusual advantages. He wants only a fair chance and a square deal. He will possess a certain species of solid independence that is quite the reverse

of snobbishness. He will be completely educated before graduation instead of only in part, the remainder to come afterwards. His mind will be clear and active like the spring rushing out of the rock, clear as a crystal, unlike that of a mud puddle just after a summer's thunder storm.

Instead of taking such a man as an experiment, at \$1,000 per year salary, without much of an idea of what I am really getting, I would be only too glad to recommend his appointment at \$1,500. In the first instance, if sent perhaps a thousand miles or so away, he will expect to be told just what to do and how to do it. In the second case, he will keep both mail and wires busy piling up letters and telegrams telling me what he is doing and how he does it. The one must be bolstered up, the other can not be kept down. Your senior needs no teaching or instruction. He does require judicious, kindly but firm direction and you have almost made his future.

Some things are, however, amusing, even in serious matters. Quite possibly in case of the \$1,000 man, his college paper may contain something like this: "Mr. A. B. C., '10, has just accepted a responsible position with the United States Department of Agriculture at Washington. University of X. Y. Z. men are much in demand by this great nation, and this demand appears to exceed the supply." When similar information is allowed escape from the president's office, even with an eye to increased appropriations, the effect is doubly demoralizing.

Now, as I have already explained, the amount of teaching and instruction required will be vastly reduced, but the effectiveness will be correspondingly increased. You will say, however, that I am dealing with only one phase of the problem, that of training the investigator, and

have lost sight of the systematist and teacher.

Relative to the first, let me tell you that the systematist must in future become more and more of an investigator, and, moreover, of precisely the sort I am urging you to develop. Our present system of insect classification is all well enough if you put it away and keep it in Schmitt boxes. The moment you remove it and attempt to build a biological structure upon it, it breaks down. It is too frail and loosely put together. Let me illustrate. Some years ago we had a parasite of a very destructive aphid down in our books as *Lysiphlebus tritici*. In carrying out our investigation it became necessary to find out whether this parasite had more than a single host insect, and whether it could develop in more than one species of aphid. To this end, recently emerged males and females were allowed to pair, after which the female oviposited in several species of aphids. Both parents were then killed and preserved and all of their progeny not used in further experiments were also preserved, and thus entire broods or families were kept together. In this way females were reared out of one host species and allowed to oviposit in others until often after several hosts had been employed it would be bred back into the species whence it first originated. In all cases the host was reared from the moment of birth, while with the parasite both parents and offspring were preserved and kept together. The result of this little fragment of work was to send two genera and fourteen species to the cemetery—you may call it Mt. Synonym Cemetery if you choose—while the insect involved is now *Aphidius testaceipes*. The systematist who studies only dried corpses will soon be out of date.

Now as to the teacher: there has of late grown up among universities and colleges

a traffic, of which you will find no record in commercial literature—the training of teachers and exchanging with each other—a commerce that is indicated in university and scientific publications. This is a kind of intellectual in-and-in breeding. Among animals and plants this is only practised where the intention is to establish a fixed type that will not change but remain stable. Hence it is that your type of teacher and teaching is so fixed and to a certain degree inflexible. A teacher instructs as he was himself taught to do—taught that it was the one and only way. If he departs therefrom to the extent of substituting direction for instruction he feels as though he was a discordant note, and has somehow done something not just right.

This is not intended so much as a criticism as pointing out the fact that it simplifies correction. The matter is one that the pedagogue can change and correct, because the old method has become antiquated. The time was when the pedagogue could and did decide the sort of training necessary, and perhaps it was, at that time, best that he did so, but times have changed since then. Up to not so many years ago when instruction was even more functional than now it was hard to find a university-trained man in the employ of industrial firms or corporations. Now there are many. There must, however, be still further modifications to meet the still more exacting demands at present made upon university-trained men. The business man succeeds by being the first to see a demand as well as the first to supply it. If you will allow me to put it in a homely way, the pedagogue must get down from his antiquated pedestal that is badly affected both by dry rot and *Lyctidæ* and get on to another, more substantial, of concrete and steel perhaps.

You can not suppose, for a moment, that

we can carry on investigations that, ten years ago, we would not have dared to touch, with men trained just as they were ten or twenty years ago. This is far from being a personal matter. It is our irresistible, progressive civilization, the pride of every American, that calls for improvement, and it must come. Slowly, perhaps, but surely.

It has not been my aim in this paper to unduly criticize the progressive instructor, or the institution that is doing its best to break away from the old régime, but to encourage and if possible aid both in their laudable efforts.

If I have been able to put into the hands of those who are to train our entomologists for us in future facts or arguments that will aid them to push for a more rational, natural and therefore easier, though none the less thorough and severe, university training, I shall have certainly accomplished all that was intended.

F. M. WEBSTER

U. S. DEPARTMENT OF AGRICULTURE

ON THE IMPROVEMENT OF MEDICAL TEACHING¹

THE watchword of the present is conservation. Especially in the industrial world it has been shown that great improvement is possible by the elimination of needless waste of time and energy. Though not yet so clearly recognized, this is equally true in the field of education. Teachers, especially those in the higher institutions of learning, are notoriously neglectful of the principles and technique of their profession. Unquestionably this results in great losses due to inefficient methods of teaching. These losses, in medical education, may be conservatively estimated at twenty to twenty-five per cent. In other words, the adoption of more efficient methods of teaching would probably enable

¹ Read at the twenty-second annual meeting of the Association of American Medical Colleges, Chicago, February 28, 1912.

us to gain the equivalent of a whole year within the time now devoted to the four years' curriculum. Is not the possibility of such a tremendous saving well worth our serious consideration?

At the outset, it should be clearly understood that *uniform* methods of teaching are neither necessary nor desirable. The methods in detail must be determined by the individual teacher to meet best the varying local conditions. But equally true is the important fact that all efficient methods of teaching must be based upon well-known and well-established principles of pedagogy. Efficient teaching requires three essential conditions: (1) Complete mastery of the subject-matter on the part of the teacher; (2) a clear notion of the aim of the teaching, and (3) well-chosen methods of accomplishing the aim. The first and most essential condition, that the teacher must be a master of his subject, is everywhere clearly recognized, and will not be discussed in the present paper. The second and third conditions are those oftentimes overlooked, and it is therefore necessary to emphasize certain fundamental principles of aim and methods, the neglect of which is largely responsible for inefficient teaching.

In the first place, let us therefore consider the aim of medical education. In this all will probably agree that the *primary* aim of medical education should be to train efficient practitioners.¹ And it may furthermore be taken for granted that an efficient practitioner is one who is able to observe accurately, to think clearly and to act wisely in his medical practise.

Keeping in view this primary aim and ultimate purpose of medical education, to train efficient practitioners, we may next consider the methods, the ways and means, whereby this aim is to be accomplished. If the end is to be reached most directly, if the student is to be trained most economically for the great-

¹In addition to the education of practitioners, the medical school has other important functions, such as the advancement of medical science through original investigation, but these are not within the scope of the present paper.

est efficiency, it is evident that the instruction must be adapted to his nature and learning capacity. How shall this be done? Let us see whether there is any rational principle to guide us in adapting our methods to the nature of the student. Upon this question an important light is thrown by the history of education.

A century ago, practically all teaching was based upon the doctrine of authority. It was the function of the teacher to *tell* the student what he should know and do. It was the duty of the student to be a passive recipient, to follow faithfully the precepts of the teacher. This doctrine of authority, however, was found inefficient and has long since been abandoned in rational education. It is now generally recognized that all education really worth while is based upon *self-activity*. This principle, advanced by Froebel, is now so thoroughly established in education that it may almost be taken as self-evident. Self-activity is the keynote of modern pedagogy. And yet, while recognized in theory, this fundamental principle is often almost totally neglected in practise. In the light of this principle of education by self-activity let us review briefly certain phases of methods in medical teaching.

In developing the self-activity of the student, it is evident that the methods first of all must arouse his interest and attention. Interest we know to be most intense in things which satisfy conscious needs. Now the medical student wants above all to be a good practitioner. If he knows that a certain thing will help him to accomplish this, he is intensely interested, and will exert an active effort to secure it. "The mind interprets impressions from without, not according to their intrinsic nature, but accordingly to their relation to the needs of the organism" (Bagley). Common sense and good pedagogy therefore agree that in teaching any subject in the medical curriculum, the teacher should make sure that the student realizes its bearing upon his later work.

Some may conclude from the foregoing that, since time is limited, only the so-called

"practical" facts, those that are of obvious utility in the practise of medicine, should be taught, and that no time should be wasted on "theoretical" aspects. While this argument may appear plausible at first glance, its fallacy is apparent on closer examination. In the first place, it is impossible in any given subject to select out only those facts which may later be needed. Moreover, even if such facts could be selected, it would be impossible to teach them as bare, empirical facts, in such a way that the student could understand, remember and utilize them, without a comprehension of the science of which they form a part. The "theoretical," as Bagley states, contributes to the coherence of the various facts and principles as *knowledge*. Its value can not be disputed, for any attempt to "cut out" the "impractical" parts invariably results in the inefficient functioning of the remainder. Short courses that give only the essentials, fifth-rate colleges and normal schools that educate you while you wait, are sufficiently damned by their own products.

There is, it must be acknowledged, some truth in both the "practical" and the "theoretical" points of view. The best methods of teaching will, therefore, utilize both. While each subject should be taught from the theoretical, scientific point of view, at the same time its practical application should be kept constantly in mind. In selecting material to develop the essential principles, those facts should be chosen which will also probably be of greatest intrinsic value for later work. Anatomy, for example, should be taught, not as a mass of empirical facts, but as a special branch of biological science. But in selecting from the huge mass of available data the facts necessary to illustrate the science of anatomy, so far as possible those facts should be chosen that are also of direct, intrinsic value in physiology, pathology and clinical medicine.

If this plan were consistently followed out, and everything excluded excepting facts, especially those of intrinsic value, necessary to develop a scientific basis, a "working-knowledge," for each branch of study, the amount of subject-matter presented in each could be

greatly reduced. We all recognize that the curriculum is now overloaded. It is impossible to teach so much and teach it well. "What men need" (according to Huxley) "is as much knowledge as they can assimilate and organize into a train for action."

To develop in accordance with the foregoing plan the most effective methods of teaching, it is evident that each teacher must understand the curriculum as a whole. The laboratory man must be familiar with the clinical work. But this is not all. Since good teaching must take into account that which has gone before as well as that which is to follow, it is equally evident that the clinical man must be familiar with laboratory subjects and methods. We can not expect the best results in medical education until there is a better understanding and more cooperation between teachers of the various subjects all along the line. As medicine progresses, all phases appear more clearly as varied manifestations of the same underlying biological science, and only when this is realized will the clinical and laboratory work be more closely knitted together.

We have seen that to interest the student and arouse him to self-activity, he should be made to realize that each subject contributes an essential part in training him for the desired end. We may next inquire as to *how* he must be self-active. Since efficiency in practise consists in accurate observation and reasoning, resulting in wise action in dealing with medical problems, his training should develop self-activity in these very lines. He must observe, think and act for himself. For this purpose almost ideal facilities exist in our laboratories and clinics. Unfortunately, however, we are far from utilizing these facilities to their fullest extent. Our methods fail to make the student self-active, especially in observation and reasoning.

First we may consider observation. This can be cultivated only by actual observation of medical phenomena on the part of the student. It is, however, a surprising fact that in many laboratories and clinics there is no opportunity for the student to make an *orig-*

inal observation. Why? Simply because through a pernicious lecture system he has already been told all about what he is to see, before he has ever had a chance to observe it for himself.

It is furthermore a fundamental law of learning (technically the doctrine of apprehension) that we can not comprehend new facts except upon the basis and in terms of previous concrete experience. Hence the dictum: "In teaching, always proceed from the concrete to the abstract; from the particulars to the general; from the known to the unknown." It is therefore evident that to give lectures preceding practical objective study not only prevents the exercise of original observation but also inverts the normal procedure in the process of learning.

Much time and energy is sometimes thus wasted in trying to teach by lectures what would be quickly and easily comprehended after the fundamental data had been acquired by objective study. In some schools, for example, the junior year is largely given over to lectures and other didactic work which is supposed to prepare the students for the actual clinical work, the latter being chiefly concentrated in the senior year. This, it seems to me, is a fundamental mistake. If there were only one alternative, it would be better to reverse this order, giving the clinics first, and the lectures later. In actual practise, however, they are best intermingled and closely correlated, care being taken always to provide the objective basis before the more abstract generalizations are considered.

Even when the practical work is placed first, however, it by no means follows that adequate training in observation will result. In both laboratories and clinics it is a common practise as a preliminary step to *tell* the student (either orally or by printed guides) what he is to see. The student thus is not required, and indeed has no opportunity, to observe for himself. Practically all there is left for him to do is to verify what he has already been told. However valuable this may be, it does *not* develop power of original observation. It is, of course, desirable to precede all

practical work with a brief introduction which will enable the student to proceed intelligently with his work. Such an introduction, however, should be merely for the purpose of explaining technical procedure and of raising questions the answer to which the student should seek by original observation.

The ideal plan is thus for the student to work out everything for himself by the method of discovery. This applies not only to the original observations, but also to the later process of reasoning, whereby we proceed from particular data to general conclusions, and thence to rational action. The method of self-activity may therefore be expressed in a negative way by the following practical rules: Never tell a student anything he can observe for himself; never draw a conclusion or solve a problem which he can be led to reason out for himself; and never do anything for him that he can do for himself.

Unfortunately, however, there are limitations to the application of this method. It is difficult to apply successfully, requiring skill and experienced judgment on the part of the teacher. Lack of time would moreover prevent the student from repeating the history of the race by the method of discovery. But though difficult and slow at first, by working out for himself at least the fundamental data, a solid basis is laid which makes possible more rapid progress later. Time lost at the beginning is thus time gained in the end. We should therefore insist that *so far as practicable* this ideal method be applied for the purpose of training the student to self-activity, in developing his ability in observation, reasoning and action.

As supplementary to the foregoing, it is usually necessary to adopt easier though less effective methods of instruction. Thus where necessary data can not be secured by original observation, they may be supplied by the usual type of laboratory or clinical demonstrations, which the student can verify. Next in value below this as a means of imparting knowledge comes the informal lecture or recitation, illustrated by demonstrations, models, pictures, etc. Next comes the

text-book, and lowest of all in the scale is the formal lecture. Curiously enough, the lecture is also the *easiest* method, by which *apparently* the greatest amount of information is gained with the least expenditure of energy, at least on the part of the student. But this is a delusion. The knowledge thus gained is unreal and transient. It is "in at one ear, and out at the other." As we should naturally expect from the principle of self-activity, the ease of the method is apt to be inversely proportional to the efficiency of the instruction. In order therefore to train our students most efficiently in self-activity, we should use the maximum amount of the more difficult but more effective methods and the minimum of those easier but relatively inefficient.

This will perhaps be made clearer by a brief illustration from personal experience. To learn, for example, the normal histology of any given organ by means of a stained and mounted section, this should first be studied by *original observation*. The students observe the structure with naked eye, low power and high power of the microscope, and without previous description by teacher, book or laboratory outline. They record their observations by sketches and brief notes. The aid of the teacher at this stage should be restricted to questioning the individual students so as to recall related facts previously studied and prevent the student from going too far astray. At first, students are apt to be utterly helpless when thus thrown largely upon their own resources, but they soon develop surprising powers of observation. This "investigation" occupies the first part of the laboratory period. The teacher then informs the class regarding the section they have studied, and discusses briefly their mistakes of observation. He directs them in restudying the section, and in correcting their mistakes. The students now extend their knowledge by verifying the statements found in their text-books. Demonstrations are made to furnish additional data and elucidate the more difficult points. Drawings are finally made by the students, to fix the corrected impressions upon their

minds. At a later class-conference, the students are led to review the facts learned, to correlate and interpret them and to reason out general conclusions or laws of structure. These laws they utilize and apply in the subsequent work. Brief written reviews are also frequently held. Occasional lectures by the teacher elucidate the more difficult phases, and indicate the relations of histology to physiology, pathology and clinical medicine. The results are satisfactory as shown by final examination, both written and practical, and by the extent to which the students are able to retain and utilize their knowledge in later work.

The foregoing method illustrates how students may be trained to self-activity in observation and reasoning, and to a certain extent in application. The application of the generalizations reached by observation plus reasoning, while essential in every subject, is especially characteristic of the clinical work. That the student should be self-active in his clinical work, that to acquire skill in the practical application of his previous knowledge he must "learn by doing," is universally recognized. It is therefore unnecessary to dwell upon this phase of the subject. It may be worth while, however, to remember that, above all, in the clinics, "the main business of the teacher is to render his services unnecessary" (Strayer).

To summarize the foregoing: it has been maintained that in medical education there is great need of more effective methods of teaching. Efficient teaching requires a clear view of the ultimate aim, which in medicine is to train efficient practitioners. To accomplish this aim, rational methods of teaching should develop in the student self-activity in observation, reasoning and action. While some may be unable to accept fully the ideas here presented, all will surely agree that great improvement would result if medical teachers would study more carefully their educational methods. The younger teachers who are so fortunately located could greatly improve their efficiency by taking work in the schools of education connected with the various uni-

versities. Those unable to do this should at least study the principles of pedagogy, which are available in numerous books. Although pedagogical literature deals chiefly with elementary, rather than advanced or professional education, it is nevertheless of great service, for the same fundamental principles extend throughout, from the kindergarten to the university. Among those books which may be recommended as helpful are the following: Spencer, "Essays on Education" (a recent edition, with introduction by ex-President Eliot, in the "Everyman's Library" series); James, "Talks to Teachers on Psychology," etc. (Holt); Charters, "Methods of Teaching Developed from a Functional Standpoint" (Row, Peterson & Co.); Bagley, "The Educative Process" (Macmillan); Thorndike, "The Principles of Teaching Based on Psychology" (Seiler). And in conclusion, permit me to suggest that a more thorough discussion of educational methods and principles in our association meetings, and also in the faculty meetings of our various medical schools, would result in greater efficiency in our teaching.

C. M. JACKSON

UNIVERSITY OF MISSOURI

SCIENTIFIC NOTES AND NEWS

PROFESSOR ABBOTT LAWRENCE ROTCH, founder and director of the Blue Hill Meteorological Observatory and professor of meteorology at Harvard University, died on April 7, aged fifty-one years.

DR. JOHN H. MUSSER, professor of clinical medicine in the University of Pennsylvania and one of the most eminent physicians of Philadelphia, died on April 3, in his fifty-seventh year.

THE second annual award of the Willard-Gibbs Medal, founded by Mr. William A. Converse, will be made by the Chicago Section of the American Chemical Society on May 17, to Professor Theodore W. Richards, of Harvard University. It may be remembered that the initial award of this medal was made last May to Professor Svante Ar-

rhénus. Professor Richards has chosen for the subject of his address "Atomic Weights." An invitation is extended to all members of the American Chemical Society, who desire to be present on the occasion of this award.

SIR J. J. THOMSON has been elected a foreign member of the Naples Academy of Sciences.

THE clay model for a bust of Commander R. E. Peary has been executed by Mr. William Couper and is now on its way to Florence to be cut in Carrara marble. The bust is a gift to the American Museum of Natural History from Mrs. Morris K. Jesup and will take its place among the other marble busts in the niches in memorial hall.

THE Paris Geographical Society will present Dr. Charcot with its gold medal for the work achieved in South Polar exploration by the *Pourquoi Pas* expedition.

THE council of the New Zealand Institute, at its annual meeting held in Christchurch at the end of January, decided to award the Sir James Hector memorial medal and prize to Dr. L. Cockayne as the investigator, working in New Zealand, who has done most to advance botanical science.

THE Academy of Science, the medical faculty of the University of Havana and several other scientific societies and institutions have passed a joint resolution in which the names of Dr. Carlos J. Finlay and Dr. Aristides Agramonte are presented to the Nobel Prize Commission as candidates for the prize to be awarded in 1912. The resolution points out that Dr. Finlay was the first to claim that yellow fever is transmitted by the mosquito, while Dr. Agramonte is the sole survivor of the United States Army Board composed of Drs. Reed, Carroll, Lazear and himself, which demonstrated the correctness of this theory.

THE magazine *Good Housekeeping* announces that Dr. Harvey W. Wiley, formerly chief chemist of the United States Department of Agriculture, became contributing editor of that magazine on April 1. The magazine has established at Washington a "Bu-

reau of Foods, Sanitation and Health," of which Dr. Wilay will be director.

INSTRUCTORS and students of the forestry department of the University of Michigan entertained Professor Filibert Roth recently at a farewell dinner. Professor Roth's resignation from the University of Michigan will take effect in June, and he will become the head of the forestry department of the College of Agriculture at Cornell University next fall.

DR. J. C. WILLIS has retired from the directorship of the Royal Botanic Gardens, Peradeniya, Ceylon, to become director of the Botanic Gardens at Rio de Janeiro.

DR. EUGEN KUEHNEMANN, professor of philosophy at the University of Breslau, Germany, and recently German exchange professor at Harvard University, has been appointed as the first German university professor to occupy the Carl Schurz memorial professorship established last year in the University of Wisconsin by German-American citizens of Wisconsin and friends of the university.

DR. SEVERANCE BURRAGE has resigned as professor of sanitary science in Purdue University, Lafayette, and will spend several months in Europe, after which he will take charge of the biologic and serum department for an Indianapolis drug house.

PROFESSOR F. W. CARPENTER, of the University of Illinois, department of zoology, has been appointed American reviewer for *Zentralblatt für Normale Anatomie und Mikrotechnik*.

PROFESSOR JOHN T. STEWART, of the University of Minnesota, has been authorized by the regents to attend the National Drainage Congress in New Orleans this month at an expense not to exceed \$100.

MR. DONALD F. MACDONALD, geologist to the Isthmian Canal Commission, has been granted three months leave of absence from his duties with the Commission to make a geological study of the disputed territory between the republics of Panama and Costa

Rica. Mr. MacDonald sailed from Colon for Bocas del Toro, near the Costa Rican border, on April 1. From there he will proceed by small boat and by native porters to the region to be examined.

ACCORDING to a cablegram to the New York Times the Austrian Red Cross Society will be represented at the International Conference of Red Cross Societies, which meets in Washington on May 7 to 17, by Dr. Maurice Victor Silbermark and Dr. Yetta Silbermark Reising, who sail by the *Auguste Victoria* on April 16.

MR. ARTHUR S. WATTS was elected president and Edward Orton, Jr., secretary of the American Ceramic Society at the recent Chicago meeting.

PROFESSOR GEORGE GRANT MACCURDY will be the delegate from Yale University to the International Congress of Anthropology and Prehistoric Archeology to be held in Geneva, Switzerland, during the first week of September, 1912.

THE following delegates have been appointed to represent the American Philosophical Society on the following occasions: Vice-president William B. Scott, of Princeton, to represent the society at the two hundred and fiftieth anniversary of the foundation of the Royal Society in July next; Professors Paul Haupt, of Baltimore, E. Washburn Hopkins, of New Haven, Morris Jastrow Jr., of Philadelphia, and A. V. Williams Jackson, of New York, as delegates to the eleventh International Congress of Orientalists, to be held at Athens on April 7 to 14; Dr. Franz Boas, of New York, a delegate to the eighteenth International Congress of Americanists, to be held in London from May 27 to June 1. At the centenary of the Academy of Natural Sciences on March 19 to 21 the society was officially represented by Professor Henry F. Osborn, of New York, Dr. Charles D. Walcott, of Washington, Mr. Samuel Vauclain, of Philadelphia, Professor Wm. Bullock Clark, of Baltimore, and Dr. Henry H. Donaldson, of Philadelphia.

THE tenth annual meeting of the South African Association for the Advancement of Science will be held in Port Elizabeth from July 1 to 6, under the presidency of Dr. A. Theiler. The sections and their presidents are as follows: A, astronomy, mathematics, physics, meteorology, geodesy, surveying, engineering, architecture and irrigation, Mr. H. J. Holder; B, chemistry, geology, metallurgy, mineralogy and geography, Professor B. de St. J. van der Riet; C, bacteriology, botany, zoology, agriculture, forestry, physiology, hygiene and sanitary science, Mr. F. W. FitzSimons; D, anthropology, ethnology, education, history, mental science, philology, political economy, sociology and statistics, Mr. W. A. Way.

THE fifth of the Weir Mitchell lectures of the College of Physicians, Philadelphia, was delivered on March 29 in Mitchell Hall, by Dr. William H. Howell, of the Johns Hopkins University, on "The Factors concerned in the Coagulation of Blood and their Variations under Pathologic Conditions."

UNIVERSITY AND EDUCATIONAL NEWS

THE board of directors of the Knights of Columbus announces that \$385,000 of a \$500,000 endowment fund for the Catholic University in Washington already is in hand. The income from this fund, the remaining \$115,000 of which has been subscribed, will be used to provide scholarships for fifty students.

THE Berlin correspondent of the *Journal* of the American Medical Association writes that according to the official estimate of the expenses of the Prussian universities, for the fiscal year 1912, they will amount to \$5,016,389 (20,065,556 Marks). Of this amount \$2,202,058 is to be spent for institutes, collections and the university religious services. For salaries, remuneration and other personal expenses of the professors, instructors, officers, assistants and employees \$2,059,466 are allowed and for lodging allowance \$288,687. For the expenses of the academic management \$93,266 are appropriated, for the building expenses \$200,275 and for taxes \$9,868. For contingent expenses \$110,970 are provided,

and \$51,195 are appropriated for relief and stipends. The entire expenses are distributed among the individual universities as follows: Berlin, \$1,184,515; Breslau, \$541,311; Halle, \$546,982; Bonn \$485,146; Kiel, \$482,741; Göttingen, \$463,215; Königsberg, \$411,621; Greifswald, \$366,475; Marburg, \$348,326; Münster, \$168,158, and Braunsberg, \$17,395. The expenses are to be met by the following income: from the state fund, \$3,636,801; from endowments and other funds, \$178,928; interest from capital and the income from real estate, \$119,619, and from their own earnings, \$1,081,039.

PLANS are well under way for the new building for the department of clinical medicine at the University of Wisconsin. The department exists for the purpose of looking after the health of the students in the university. There is a corps of five doctors and four trained nurses who are kept busy ministering to sick students or taking precautionary measures in the case of those exposed to disease. The new building will have ten offices on the first floor for the treatment of common ailments, and in the basement will be a sterilization room and special treatment rooms, fitted up with X-ray machines, baking machines and other special equipment. The value of having a department to look after the health of students is shown by the fact that there have been no epidemic diseases among the students that were not controlled as soon as the first cases appeared, since the establishment of the department. Previous to its establishment, there were a number of bad epidemics among students, the most serious of which was an outbreak of typhoid fever in 1907 which resulted in the death of several students.

THE *Journal* of the American Medical Association states that the professors of the University of Dijon have unanimously passed a resolution calling for a university congress to organize the French universities more closely and to extend their influence abroad. There has been founded under the auspices of the France-Amérique committee a league to foster French interests in America, which

has for one of its objects to make known to the public of the two Americas the value of French general culture and practical instruction.

DR. CHARLES E. MARSHALL, professor of bacteriology and hygiene in the Michigan Agricultural College, has accepted an appointment as director of the graduate school and professor of microbiology, at the Massachusetts Agricultural College. He will begin his new duties on September 1. The Graduate School of the Massachusetts Agricultural College is an outgrowth of graduate work started under the direction of Professor Charles H. Fernald nearly eleven years ago. Four years ago the school was organized with Professor Fernald as director, and since his retirement Dr. Henry T. Fernald has been acting director. During the existence of the school fifteen men have been given the degree of master of science, and seven, the degree of doctor of philosophy. At the present time sixteen men are enrolled as graduate students. It is the intention of the trustees to develop the activities of the school.

DR. RAYMOND A. PEARSON, recently Commissioner of Agriculture for the state of New York, has accepted the presidency of the Iowa State College of Agriculture at Ames. Dr. Pearson has been granted leave of absence for the summer and will visit agricultural colleges in Europe.

DR. THOMAS McCRAE, A.B., M.D., Toronto, associate professor of medicine at the Johns Hopkins University, has been appointed professor of medicine in Jefferson Medical College, Philadelphia, to fill the chair vacant by the resignation of Professor James C. Wilson.

At the University of London Professor F. G. Donnan, F.R.S., has been appointed to the chair of general chemistry at University College, in succession to Sir William Ramsay. Dr. L. N. G. Filon, F.R.S., has been appointed to the Goldsmid chair of applied mathematics and mechanics to succeed Professor Karl Pearson, who resigned this chair on his appointment to the Galton chair of eugenics.

DISCUSSION AND CORRESPONDENCE

ARE HORNS IN SHEEP A SEX-LIMITED CHARACTER?

ARKELL and Davenport in *SCIENCE* for March 8, 1912, answer this question in the affirmative on the basis of certain crosses which they have made between horned and hornless races. In doing so they call in question the authenticity of a statement made by me in a recent publication as follows:

In merino sheep the male has well-developed horns, but the female is hornless; yet if the male is castrated early in life no horns are formed.

They comment thus:

He gives no references for the last statement; and in view of the variability of the horned condition in the males of the "merinos" the conditions of the experiments would have to be carefully considered before such a result could be accepted as settling the question of the dependence of horns in heterozygous males upon a secretion from the testis.

In reply to this criticism, I beg to say that I gave no authority for the statement in question because I can myself vouch for it. I grew up on a farm where Merino sheep were kept in considerable numbers. From my earliest recollection until I was 21 years old I saw the operation of castration practised each year on 50 or more ram lambs and its effects were perfectly familiar to me. The result is exactly that stated. If the male is castrated early in life, say within a month after birth, no horns develop. If castration has been delayed for two or three months, the horns begin to grow, but castration then promptly arrests their growth. I can recall but one exceptional case in the hundreds that came under my observation. In that case the horns continued to grow for some weeks. When this case was observed, the animal was caught and found to have been imperfectly castrated. A second operation caused cessation of the horn development. My father used registered Atwood Merino rams, and his ewes were pure bred. The ewes were regularly hornless as they are typically in this breed. See figures in Robert Wallace's (1907) "Farm Live Stock of Great Britain," p. 592. The males were as regularly horned, if not castrated. We usually

raised several of these (uncastrated) males each year and they were remarkably uniform in horn development. Compare again Wallace's figures, which are accurate, being photographs. Arkell and Davenport's statement concerning the "variability of the horned condition in the males of the Merinos" leads me to think they must refer to *grade* Merinos, certainly not to the pure bred ones.

To my mind the evidence is clear that in pure Merino sheep castration does prevent development of the horns, and I have no doubt that in other breeds also castration has similar though perhaps less conspicuous effects. In breeds which are horned in both sexes the males regularly have *better developed* horns than the females, and castrated males have smaller horns than uncastrated ones. See figures in Wallace.

If castration has the effect stated, the assumed nuclear *inhibiting* factor of Arkell and Davenport is quite superfluous. Their experimental results are fully in accord with those of Wood and are fully covered by the simple statement of Bateson that the horned character is "*dominant in males and recessive in females.*" Why this is so I have attempted to point out. Presence of the testicle is necessary for full horn development, in some breeds it is necessary for *any* horn development. Reasoning from the experimental results obtained in poultry it seems probable that injections of testicle extract into the female would cause increased horn development similar to that of the male. It would be interesting to know whether the testicle of all breeds would behave alike in this experiment. Whether the female sex gland acts as an inhibitor of horn development would be a wholly different question, yet one capable also of experimental solution.

To assume, as Arkell and Davenport do, that inhibiting factors present in X-chromosomes affect the horn development seems to me unwarranted, for the simple reason that neither inhibitors nor X-chromosomes are known to exist in sheep. That Guyer has recognized the existence of an X-chromosome in man has no very direct bearing on the

question, but even Guyer's result is unconfirmed by Guthertz, who has reinvestigated the spermatogenesis of man upon exceptionally favorable material.

Arkell and Davenport reason thus:

The results of the table [of crosses] accord very closely with expectation, so that we are justified in concluding that an explanation of the results like that we offer is the correct one.

But Bateson's explanation accords also; wherein lies the superiority of the new one offered? To establish the probable correctness of a hypothesis it must be shown that no other hypothesis accords with observed facts equally well. Has this been shown in the case before us?

Consider how one unproved hypothesis has been added to another. First it is assumed that in hornless animals a gene for horns has either been lost or is inhibited. It is equally probable that no gene has been lost and that nothing is inhibited. Secondly, it is assumed that one inhibitor is inferior to one horn-gene in power, but that two inhibitors surpass one horn-gene, yet two inhibitors are themselves overpowered by two horn-genes; without all three of these ungrounded assumptions of the relative valency of imaginary genes the explanation fails altogether. Further, it is assumed that the female is capable of carrying two inhibitors, but the male only one. And finally when this colossal structure of hypothesis encounters one well-known physiological fact, the result of castration, that fact is calmly brushed aside. Is this a desirable extension of Mendelian interpretation?

THE MOTH OF THE COTTON WORM (ALABAMA ARGILLACEA HUBN.)

TO THE EDITOR OF SCIENCE: In connection with the notices appearing in SCIENCE (October 16, November 10 and December 29), concerning the moth of the cotton worm and the destructive work of the caterpillar on cotton, a note from Missouri may be of interest.

During the fall this moth was present in great numbers in various parts of the state.

The northward migration seems to have been quite general. They made their first appearance in the vicinity of Kansas City early in September, and by September 26-30 were present in countless swarms at Kansas City and Holden. They reached Macon in north Missouri September 24, and were very abundant and troublesome until frost. Here at Columbia they were especially abundant the last two weeks of September and early October; while later in October the moth of the army worm (*Leucania unipunctata*) was far more abundant, collecting about cider mills and injured and decaying fruit. With conditions favorable next year, we may expect considerable injury from the army worm in this state.

One point with reference to the moth of the cotton worm which the other notes have not brought out, is the injury which they do to ripening fruit in the orchard and where fruit is exposed in the market. This has been especially emphasized in all the letters received at this office this fall. As is well known, this moth has rudimentary mandibles by means of which it can break the skin of fruit and then with its proboscis it sucks out the juices. Late peaches, especially Heath Clings, are reported as having been severely injured this year. In some cases a dozen or more at a time collect on a single peach and eventually all the juice is consumed, leaving only the skin, pulp and pit. Grapes and even bananas in the market are attacked. In the orchard, after the peaches were picked, the moths turned to the apples. Their attack on the apple is similar to that on the peach except that the juice is drawn out in patches which turn brown and become mellow like bruises. The affected patches vary from the size of a pea to that of a dime or a quarter. The most of the fruit so attacked decays.

The strange northward migration of this moth which has always been of considerable interest to the entomologist has proved to be of special interest to many of the Missouri fruit growers this year.

CRYSTALLOGRAPHIC TABLES

TO THE EDITOR OF SCIENCE: As a teacher of crystallography I have found that students rarely appreciate the full significance of the fundamental laws of the science until, by actual measurement and calculation, they have found concrete evidence. With large crystals of quartz, calcite, tourmaline, zircon, rutile, barite, staurolite and a number of others, satisfactory results may be obtained by use of the Penfield hand goniometer. The advantage of such crystal measurement is twofold; it illustrates the laws which govern the arrangement of crystal planes, and it teaches the value of the science as a means of mineral determination.

Regarding the latter phase of the study, students are taught the methods of measurement and calculation necessary in each system for the determination of axial ratios. To bring out clearly the real value of such calculations as a means of practical mineral determination some sort of reference table of axial ratios seems desirable. Such tables have been compiled in a somewhat imperfect form, and it is to these that attention is directed.

The axial ratios of common tetragonal and hexagonal minerals are arranged in ascending values of c , the mineral names being placed in a parallel column. In practise the chart is placed before a class with the mineral names covered. After careful measurement and calculation the student refers to the column of ratios, and the fact that he can, in many cases, determine the mineral properly by this means alone, makes it a most illuminating and interesting exercise.

The orthorhombic system presents considerable difficulty in compiling a table of ratios since there are three possible ways in which the values of a , b and c may be arranged and still be in accord with the convention that b must be greater than a . Having determined the axial ratios, one is in doubt as to the proper arrangement. The three possible values of a , which may occur, b being unity, are the value of a when (1) c is greater than a and also greater than b ; (2) c is greater than a and less than b ; (3) c is less than a

and less than b . The most useful table, one which precludes the necessity of rearrangement or recalculation, is one which includes all three of these possible values. For the most common orthorhombic minerals such a table has been arranged with the values of a in increasing order of magnitude, the corresponding values of c and the mineral names being placed in parallel columns. Thus each mineral appears three times, and the value of a accepted by convention is underlined. The corresponding value of c in the parallel column is a very useful check in tracing the unknown mineral.

If a monoclinic mineral is held with the greatest possible number of faces vertical, the most probable mistake in orientation is the interchange of a and c axes. Hence the table is made to include both a and c as possible values of a , *i. e.*, each mineral appearing twice in the table.

Would such tables, enlarged to include all minerals for which axial ratios have been determined, be useful accessories in the work of crystallographic mineral determination with the reflecting goniometer? Would tables further enlarged to include artificial crystals be of use to the chemical crystallographer?

Before undertaking such a task one wishes to know if it is worth while, and for this reason the questions are presented. Suggestions, and the utmost freedom of criticism by teachers of crystallography, are invited.

HOUSE AIR

TO THE EDITOR OF SCIENCE: I had occasion recently to consult the issue of SCIENCE for September 29, 1911, and read for the first time the letter on "House Air" from Professor J. Y. Bergen, of Cambridge.

He makes this statement regarding the ventilation obtained from a hot air register:

The ventilation . . . is much better than can be obtained in summer by opening a single window to its full height.

It is doubtless known to him and should be

more widely known that it is better to pull the window down a couple of inches from the top and up from the bottom when ventilation is required than to open either half only. The truth of this statement can easily be tested by holding a lighted candle at the window openings.

QUOTATIONS

MOST RECENT INVESTIGATIONS ON THE DETERMINATION, PRESERVATIVE ACTION AND ADMISSIBILITY OF THE USE OF BENZOIC ACID¹

PART II²

I NOW come to the most important part of my work—a critical summary of the three detailed investigations on the effect of benzoic acid and of benzoates on man which have been carried out during the last four years and which now furnish us that broad basis, which I have always desired, necessary for the formation of an intelligent opinion. First, there are two great works from the American Department of Agriculture; one carried out by H. W. Wiley,³ in 1908, the other by a commission, under the chairmanship of the distinguished chemist, Ira Remsen, consisting of the three well-known American scientists, Professor Russell H. Chittenden, of Yale University; Professor John H. Long, of Northwestern University, and Professor Christian A. Herter, of Columbia University, New York. It seems strange that a great government should publish two books, one right after the other, dealing with the same subject-matter; and we seek in vain, in the second large volume of 761 pages, for a word of explanation of this surprising fact. Wiley's work is simply ig-

¹ Translated from the *Chemiker-Zeitung*, Cöthen, November 28, 1911, pp. 1314-17.

² Part I. (*Chem. Ztg.*, 1911, pp. 1297-99) is a summary of the articles dealing with the isolation, qualitative and quantitative determination, natural occurrence in plants, preservative action, use and toxic effects of benzoic acid.

³ *J. Soc. Chem. Ind.*, 28, 67 (1909).

nored in the publication of Chittenden, Long and Herter, as if it had never existed! From this it may be concluded at once that the results or conclusions of Wiley did not seem, to the second commission, worth discussing. This is so much the more surprising in that Wiley, under the authority of the Department of Agriculture, has, for years, been publishing similar investigations on boric acid, salicylic acid, etc. Under these circumstances I had at first thought of leaving Wiley's work entirely out of consideration, but since Dr. V. Gerlach, of Wiesbaden, in the third^d of the detailed publications mentioned above, expresses his regret that he had access to only a short abstract of Wiley's investigation, a discussion of the original, which now lies before me, will be appropriate, especially as the work will become even more difficultly accessible in the future.

Wiley studied the effect of benzoic acid on six persons and that of sodium benzoate on six others. In each case a 10-day period without the preservative was followed by a 5-day period with 1 gram, then by periods of equal length with 1.5, 2.0 and 2.5 grams, each, of the preservative, and finally by another 10-day period without the preservative; *i. e.*, 40 days, in 20 of which benzoic acid was administered. Above all, it is to be regretted that the preparations were given in capsules and that the small quantities (0.25–0.5 gram) which, in practise, are most important were not administered, as the minimal dose was 1 gram; and finally, that the experiments were extended only over a relatively short time. As far as concerns the results, I cling to the good custom of not doubting an investigator's facts and analytical data; only the basis and logic of the conclusions are here discussed. From the experiments, which are reported carefully and in considerable detail in 250 pages, Wiley concludes some very disadvantageous things for benzoic acid. He finds:

It is evident that the use of benzoic acid, either as such or in the form of sodium benzoate, is

highly objectionable and that it produces grave disturbances of the metabolism and health (irritation of the stomach, nausea, headache and, in a few cases, vomiting). So much the more importance is placed on these symptoms as they were observed in healthy men, well and carefully fed. All the test persons showed a distinct loss in weight and all the more or less marked changes in metabolism shown by investigation of the urine and feces were always of such a nature that they could never be regarded as a favorable change.

In my opinion, this sentence might just as well read: Careful investigation of the urine, feces and metabolism did not show a single symptom from which a disturbance due to the partaking of benzoic acid might be deduced! That the normal condition could not be improved by benzoic acid, as Wiley seems to require, is not surprising. As Wiley is thus far the only investigator who, supported by comprehensive experiments, has formed a condemnatory opinion of benzoic acid on toxicological grounds, I have taken the trouble to criticize his work somewhat more closely and to examine the value of his arguments. The very thorough examination of the urine, which is reported in many tables, showed nothing special. Who could lay much value on the fact that in the benzoic-acid periods the amount of solid substances in the urine increases 2.3 grams, *i. e.*, from 55.5 to 57.8, when, in the first place, the diet is not strictly fixed and, secondly, the addition of 1–2 grams of benzoic acid per day almost completely covers the increase. The relation of sulphur to nitrogen, sulphuric acid to nitrogen and phosphoric acid to nitrogen remained entirely unchanged; with the arbitrary diet the variations of 1–3 per cent., either way, of the values are unavoidable. The alkylsulphuric acids remained perfectly constant, the absolute amount of urinary sulphur changed only to an insignificant degree explainable by the method of procedure; a decrease of neutral sulphur from 14 to 12.4 per cent. in the benzoic acid period and to 11.1 per cent. in the after period seems to be proved, while on the other hand the total sulphur shows an increase from 85.9 to 87.7 and 88.9 per cent. But any one wanting to

“*Physiologische Wirkungen der Benzoesäure und des benzoesauren Natrons*,” Verlag von H. Städt, Wiesbaden, 1909.

draw any conclusions from this might just as well, instead of supposing, like Wiley, an increase of oxidation, infer that the oxidizing power of the body is distinctly increased a little by rather large doses of benzoic acid and increases still more after the excretion of the benzoic acid, a sign of an especially powerful cell activity. It is an interesting fact that the separation of benzoic acid as hippuric acid does not take place very quickly but that an after period following a rather prolonged benzoic acid diet still shows increased hippuric acid. The microscopic investigation of the urine—the method is not described in detail—was made six times in all for each of the twelve persons studied—once each in the fore and after periods and four times in the benzoic acid periods. The results are represented by numbers: 0=nothing, 1=very little, 2=little, 3=considerable, 4=much, 5=very much. The following substances were sought for: crystals of uric acid, oxalates and phosphates, amorphous phosphates, epithelial cells and leucocytes, hyaline cylinders, finely granulated and coarsely granulated cylinders, mucous cylinders, mucous fibers. The numbers were added for the twelve persons and divided by twelve, and the values so obtained compared in percentages! According to the mean values most of the organized elements are increased somewhat; leaving out the crystals, the leucocytes and the finely and coarsely granulated cylinders are somewhat increased, the hyaline cylinders somewhat diminished and the mucous fibers hardly appreciably increased. Considering how strongly a 2 influences the 1's and 0's which are found in greater number, it is preferable to consider more closely each individual constituent of the six series. When this is done it is found that, excepting the mucous cylinders (increase of 50 per cent.), nothing at all remains of all the construed increases. But as the mucous fibers do not markedly increase, I set no importance on the increase of the mucous cylinders. Wiley, however, concludes that there is a slight tendency towards an increase of renal activity during the benzoic acid periods. This "slight tendency" to

cause everything that is possibly bad is construed everywhere that Wiley can say nothing definite. In the feces nothing remarkable was found. On an average, in the experiments with benzoic acid the feces were a trifle drier, in the benzoate experiments somewhat damper, during and after the administration of the preservative than before it was given.

That the majority of Wiley's twelve persons should have lost 0.5–2.0 kilograms on a freely chosen diet is very remarkable, and we should much like to learn more as to the principles on which the amount of food was measured. The amounts of dry substance, fat, nitrogen and calories daily taken in the individual periods vary not inconsiderably—with a "faint tendency" in most cases to decrease in the course of the forty days—which alone explains the slight decreases in weight. We do not learn why a greater regularity in the taking of food was not striven for. I reproduce some particulars concerning one person: Test Person 1 (C. W. N.) had nothing particular to complain of against benzoic acid, but found that his strength decreased markedly, so that he could hardly do his work. At the same time, however, it is stated that this person was often very hungry, that the abundant and varied food with 4,000 calories was not sufficient for him. On the other hand, it is seen from page 1090 that during the fore period this person partook of 606 grams of dry food, on the average during the total benzoic acid periods, of 590 grams, and in the after period, of only 567 grams. Why more food was not given him remains incomprehensible, as he had already decreased 0.5 kilogram in weight in the second 5-day fore period and 0.3 kilogram in the first 5-day benzoic acid period and was hungry! In this record I see nothing but decreased body weight and consequent feeling of weakness, probably increased by suggestion, resulting from a somewhat too limited consumption of food. To other persons was given 1 per cent. of the body weight in dry substance, to No. 1 only 0.87 per cent. On page 1166 we learn, to our surprise, that Person 1, who daily took about 13–14 grams of nitrogen, daily gained

(in spite of decrease in weight) 0.53 gram nitrogen in the fore period, 0.39 gram in the benzoic acid period and 1.41 grams in the after period, and therefore apparently became poorer in fat and richer in albumin. And we learn further that Person 1 did not at all stand alone in this respect. In spite of decreases in weight and disturbances of metabolism of subjective nature, five of the twelve persons increased, seven decreased, in nitrogen; in the average of all twelve experiments there was even, in all the periods and sub-periods of the 40-day test, a daily increase of 1.2-1.5 grams of nitrogen. The nitrogen was used to the best advantage; on an average for all the test persons, 7.28 per cent. was excreted in the feces in the fore period, 7.44 in the benzoic acid period and 8.16 in the after period. The phosphoric acid metabolism was hardly influenced, but it is true, as Wiley brings out, that during the benzoic acid period the phosphoric acid increases a trifle (about 3 per cent.) in the feces and decreases by about the same amount in the urine; in the after period the increase in the feces and the decrease in the urine were somewhat more marked. Wiley draws no conclusions from this. This might be considered as a poorer utilization of the phosphorus of the food, but greater guarantee as to the amount and nature of combination of the phosphorus compounds given would be necessary. That the number of blood corpuscles would also show variations was clear. Their number was greatly raised, as compared with the fore period, after 2 administrations of benzoic acid; considerably decreased, as compared with the fore period, after 3 administrations; was about the same as in the fore period after 1 administration; increased after 3 doses of sodium benzoate; decreased after 2 doses; not determined after 1 dose.

The general average for all twelve persons was as follows:

	Red Corpuscles	White Corpuscles	Hemo- globin Per Cent.
Fore period	5,082,273	7,433	96
Benzoic acid period	5,099,583	7,331	96
After period	5,355,000	6,644	97

No conclusion, therefore, for or against benzoic acid can be drawn from these data, yet Wiley speaks of a "tendency" to diminish the red corpuscles which benzoic acid seems to have!

In my honest opinion, Wiley's publication is lacking in every proof, every objective proof, of the harmfulness of benzoic acid, and from the voluminous metabolism investigations which Wiley has so pitilessly used against benzoic acid exactly the opposite conclusion may be drawn, that, at most, each and every entirely subordinate fact (I have carefully reproduced them all above from Wiley's publication) remains somewhat doubtful in its significance. From Wiley's report on subjective symptoms of digestive disturbances by 1-2 gram quantities of benzoic acid in wafers, no conclusions can be drawn; even with this method of procedure, so ill-adapted to our problem, the data stand too isolated in the literature. They give the impression that suggestion played a considerable part in them, for there is no doubt that in Wiley's laboratory preservatives are considered with extreme mistrust and antipathy and that the test persons should imbibe some of this antipathy is easily conceivable. I surmise that this was also the general impression of the American authorities and that new investigations by Chittenden, Long and Herter were instituted to critically test Wiley's results, which were contrary to all observations so far made in the laboratory and in practise.

Although the volume of analyses and observations reported by Wiley and their evident cost are considerable, the extent of the work of the other investigators is surprising. This voluminousness of the work, especially the numberless tables, makes it difficult to enter very much into the details of it. Moreover, it is really a question of three independent pieces of work. The three gentlemen, entirely independently of each other but following a carefully preconcerted plan, each subjected 6, 6 and 4 young physicians and chemists, respectively, to metabolism investi-

gations lasting not less than four months. There were thus $16 \times 120 = 1,920$ test days. On 40 of the 120 days, *i. e.*, on 640 days, exact urinary analyses were made. The benzoic acid was given in the following manner: In a fore period of 10 days no benzoic acid was given, then for two months 0.3 gram was given daily, then none for 5 days, 0.6 gram for 7 days, 1 gram for 7 days, 2 grams for 7 days, 4, 6 and 10 grams, respectively, for 7 days, and finally for 10 days no benzoic acid was given (the individual experimenters worked a little differently); the benzoic acid was mixed with the food and given as sodium benzoate. It must also be pointed out that the test persons were not exclusively of especially robust health; in fact, some of rather moderate constitution were taken.

In the first pages of the work is given, briefly, clearly and concisely, what interests us most, the conclusions of the three investigators.

Sodium benzoate in small doses, less than 0.5 gram mixed with the food, is without toxic effect and does not disturb health. Sodium benzoate in large doses, up to 4 grams mixed with the food, showed, upon investigation, no harmful effect in the general sense of the word. In some directions were observed small changes in certain physiological processes, the exact significance of which changes is not known.

According to the investigations, the mixing of sodium benzoate in smaller or larger doses has no unfavorable or deteriorating influence on the value of such food. In this series of experiments, also, the test persons were not in exact nitrogen equilibrium. They were allowed to enjoy at will, within certain limits, quite complicated, extremely varied and dainty foods, the food being merely weighed and analyzed. The daily consumption of food, which, in Germany in such experiments, we keep as nearly as possible uniform in nature and equal in amount, varied not inconsiderably, even though it must be confessed that the daily consumption of food by this method was relatively uniform. We can, therefore, without more evidence, just as easily draw favorable conclusions for

benzoic acid from the slight increases in weight which almost all of these well-fed test persons showed as unfavorable ones from the opposite facts in the Wiley experiments. It only shows that benzoic acid is not grossly harmful. Exact metabolism observations in the absolute sense are, also, impossible; only relative values can be discussed exactly, and here, too, the so widely varying nutrition is a somewhat disturbing factor.

The utilization of dry substance, fat and albumin, as we are accustomed to observe it in Germany, is not ascertained here. But I have convinced myself, from a series of values which I have calculated, that no influences on the utilization are to be observed. The corpuscular elements in the urine were not, contrary to the observations of Wiley, increased. No general symptoms were noted, either with the smaller or the larger doses. Of the numberless details of the three investigations we can safely say that, like Wiley's, they show that in almost all special cases nothing essential is changed by the administration of benzoic acid; I may therefore confine myself to picking out a few points. Chittenden expresses, at the end, his extraordinarily favorable opinion that sodium benzoate, up to a dose of 4 grams daily, is no more disturbing or harmful to the human organism than the same quantities of salt. * He makes no reservation in any direction, draws no suspicious conclusions from his observations, not even from the establishment, by Wiley's results, that the excretion of benzoic acid as hippuric acid in the urine is somewhat retarded. Long obtains very favorable results; he did, indeed, observe in his uneducated test persons (institute help, etc.) a slight disturbance at times (headache, vomiting, disturbance of sight, excitement) but always found a plausible explanation for it and never feels forced to ascribe it to benzoic acid. Herter noticed, especially with large doses, a slight increase of indican in the urine, but no change in the alkylsulphuric acid, a decrease of the fecal bacteria which evolve gases and an increase of the cocci as compared with other bacteria in

the feces. All these facts find a natural explanation in a somewhat decreased carbohydrate fermentation in the feces and somewhat increased scission of albumen, owing to certain bacteria or bacterial functions being favored by the benzoic acid at the expense of others; no one will interpret this as being hygienically dubious. Herter's values (p. 747) show very prettily the smooth transformation of benzoic acid into hippuric acid; according to his experiments, there is no appreciable retardation. A striking fact in all four of Herter's test persons was the increase of free hydrochloric acid in the expressed gastric juice during large benzoate doses, which could easily be considered as a symptom of irritation of the stomach, but is also capable of other explanations. Gerlach's experiments (see below) showed nothing of this in man or animal. There are many other details in this voluminous book, but they are hardly of significance for the problem and I have tried to bring out anything that might be disadvantageous for benzoic acid.

Most perspicuous to us Germans is the investigation carried out by Dr. Gerlach, of Wiesbaden, by German physiologico-pharmaceutical methods and which, though far behind the American works in scope and extent, can be the more easily surveyed as a whole. Small, medium and large doses were tested on animals and men. I shall not enter into the details of the experiments with rabbits, which were able to take very large doses of benzoic acid without any effects. One gram of benzoic acid was borne subcutaneously by a rabbit for 12 days without harm; a dog was fed with 7.5 grams of sodium benzoate in one dose without disturbing effects; in experiments on the investigator himself, 10 grams of benzoic acid, taken within 3 hours, had no influence on the pulse, respiration, body temperature, digestion and general well-being. (Not every stomach can stand such a dose!—Abstractor.) Two persons daily took 0.5 and 1 gram of benzoic acid and sodium benzoate, respectively, for 80–90 days without any effect. The most careful observation showed

no special disturbances of the respiration, pulse or body temperature after taking 1 and 2 grams of benzoic acid and sodium benzoate, respectively. The action of the digestive ferments, gastric juice, trypsin and the diastatic ferments was not influenced by benzoic acid and sodium benzoate. Three and five grams of benzoic acid and sodium benzoate had no influence on the quantity, acid content and digestive power of the gastric juice of a dog subjected to the Pawlow operation. Half a gram and one gram of benzoic acid and sodium benzoate, respectively, taken by the experimenter at a test breakfast, exerted no influence on the free hydrochloric acid, total acidity and digestive power of the gastric juice, collected one hour after the breakfast. In metabolism experiments on men, it was found that 1 gram benzoic acid or 1.5 grams sodium benzoate (each taken 6 successive days) had no effect whatever on the stock of albumin in the body nor on the utilization of the nitrogenous substance and fat in the food. Eighty-two doses of 1 gram each of benzoic acid, taken within 86 days, and 88 doses, taken within 92 days, showed no unfavorable effects on the general well-being, body weight, etc. At the end of the experiments, it was found that the benzoic acid, whether mixed foods or chiefly vegetables were eaten, was completely transformed into hippuric acid. Gerlach collects from the literature a large number of cases, not all of which are contained in my earlier review, and which show that large doses of benzoic acid can be taken by healthy and by sick people without harm, and he concludes with the words:

Neither the observations made in medical practice and reported in the literature nor the large number of experiments which have been carried out for the purpose seem to justify the assertion that benzoic acid and sodium benzoate in small quantities, such as they are eaten in preserved foods, are able to produce any harm whatever. The attempt to prohibit the use of benzoic acid and benzoates as a preservative would therefore not be warranted by the very copious scientific material at hand.

While the American investigators and Gerlach thus reach conclusions which could not be more favorable to those who espouse the cause of benzoic acid, the question as to the admissibility of its use is not yet wholly cleared up in Europe, especially in Germany, and an unfriendly disposition predominates. France summarily prohibited the use of benzoic acid as early as 1888, long, therefore, before its thorough investigation; in Austria, also, it was excluded from use by a decision of the chief of the Board of Health on the 16th of December, 1899, and recently again he has refused his sanction.⁵ The Landesmedizinalkollegium of Saxony has likewise refused to authorize its use.⁶

In Germany the law takes no firm stand against benzoic acid. The acquittal of dealers who introduced margarine preserved with benzoic acid into the trade in Saxony is interesting. The produce dealer Gertrud Eberlein, née Herber, who had been fined 2 Marks for dealing in margarine with 0.05 per cent. benzoic acid, had started a long trial in three courts which, however, had ended with her acquittal in the assessors's, district and provincial courts. Injury to health by such doses of benzoic acid no one could maintain; the opponents of benzoic acid among the judges asserted that benzoic acid is really a preservative, that the addition of benzoic acid makes it possible to store margarine, but that the public demands fresh margarine and that the stored product is not as good as the fresh margarine. The arguments frequently made by the judges in favor of acquittal were the following: Benzoic acid has thus far not been prohibited in Germany; it occurs in cowberries in considerable quantities; in the amounts in question it is harmless; the nutritive value, wholesomeness and usefulness of the margarine is not changed; it is therefore a preservative which, where applicable, offers great advantages long sought for, without any disadvantages. The following judicial verdicts concerning benzoic acid in margarine have come to my knowledge:

- Professor Frerichs, Bonn.

Recently the Prussian Committee on Medical Affairs has expressed itself, in a decidedly surprising manner, in favor of the prohibition of benzoic acid as a preservative for human foodstuffs and luxuries. The referees, Privy Councillors Heffer and Abel,¹⁹ frankly acknowledge, indeed, the conclusiveness of the

proof afforded by the investigations of Chittenden, Long and Herter that small amounts up to 0.5 gram are harmless to the human body, but they continue:

Whether larger amounts (quantities of several grams) could, in the long run, be borne equally without effect by everybody can not as yet be answered with certainty. The experiments of the American scientists in this connection are of too limited extent and suffer from certain limitations so that they can not be considered as proof of universal harmlessness.

With these carefully worded sentences we can, on the whole, agree without, however, drawing the conclusion therefrom that benzoic acid as a preservative is to be prohibited. For, first of all, we must consider that there are many food constituents which, under such a system, we might mistrust and likewise prohibit. I might mention hops in beer, sugar in preserves and salt in salt meat. There are, beyond doubt, many of whom it can be said with certainty that not only the repeated consumption of such things, but even a single meal off of them, is prejudicial to their health. Those suffering from urethral diseases can not stand hops, diabetes patients and persons with stomach troubles can not stand preserves, kidney sufferers can not stand salt, yet such sufferers are continually eating these things, consciously or unconsciously, without any one prohibiting them to the world. Secondly, from what has been said above it is evident that benzoic acid, considering its preservative action on acid substances poor in albumin (for others it does not come into consideration), is remarkably harmless to the healthy and the sick—with no other preservative have such daring experiments been performed on sick persons without harm. If a healthy or a sick person were given just once ten times the amount of tobacco, alcohol or even of sugar that is usually taken rationally, the results would be far worse than when, instead of 0.1 to 0.5 gram benzoic acid, 1–5 grams are given. I offered this same argument, with equal justification, many years ago to those who persisted in considering saccharin as a poison.

Thirdly, no one has thus far asked more

than that it be considered whether certain special food products might not, under proper declaration, be treated with small quantities of benzoic acid. No one, except perhaps a few manufacturers, has ever dreamed simply of a permission to add benzoic acid to foods. On the contrary, there can not be much doubt that for meat and meat preparations benzoic acid and benzoates should be prohibited; they have little preservative power and when mixed with other substances (phosphates) they help to preserve a fresh color, while the decomposition goes on; like the sulphites, therefore, they give a deceptive appearance of better condition, and according to the Heffter-Abel decision even a slight odor of putrefaction of minced meat is masked or removed by the admixture of 0.25 per cent. of benzoic acid or benzoates. No one will demand the free use of benzoic acid for tinned vegetable preserves; in these cases nothing but heat is necessary. The question is whether its use for preserving egg yolks, tomatoes, lemon juice and similar preparations, as well as margarine (and this is at present the most important), can be permitted. The first-named preparations, egg yolks, tomatoes, lemon juice, are of subordinate interest as regards public nutrition and can be passed without further discussion; even the most timid would not need to fear gravely for the public health if benzoic acid in such preparations were allowed, a statement as to the amount used being required. Personally, I am unconditionally in its favor when it is proved that these products can be prepared in a non-perishable form and kept without preservatives only with great difficulty or not at all.

The question as to allowing the use of benzoic acid in margarine, which has become a real public foodstuff, demands special treatment. One hundred and fifty million kilograms of margarine are said to be produced annually in Germany and a considerable part of it used in this country.¹² It would be very difficult today, especially for those living in cities, to protect themselves against margarine in their food. Any one in a hotel or purchasing fatty

¹² *Z. Marg.-Ind.*, 1910, 134.

confectionery or bakery wares will at once make the acquaintance of margarine; only the preparation of all food in one's own house insures safety. Margarine has won this position in spite of all compulsory declarations, in spite of the foreign-sounding name, because it fills the need of the people for a cheap fat. Leaving out one recent case where the criminal negligence of a firm in carelessly selling a poisonous foreign fat caused many cases of illness and some deaths, so far there has not been much with which margarine can be reproached.

SCIENTIFIC BOOKS

Planktonkunde. Von DR. ADOLF STEUER. Leipzig und Berlin, Teubner. 1910. Pp. xv + 728. Mit 365 Abbildungen im Text und 1 Tafel.

Leitfaden der Planktonkunde. Von DR. ADOLF STEUER. Leipzig und Berlin, Teubner. Pp. 382. Mit 279 Abbildungen im Text und 1 Tafel. M. 7. Geb. M. 8.

Many additions have been made to our knowledge of the floating life of the sea and its counterpart in fresh water, the plankton, since Haeckel published his highly theoretical "Plankton-Studien" with its elaborate but never generally adopted nomenclature and classification of this domain of life. The work of the Kiel school and its Plankton Expedition and Henson's Danaid task of taking a census of the sea, the *Valdivia* expedition with its superbly illustrated reports, the various expeditions of the Prince of Monaco, of the U. S. Steamer *Albatross* under the direction of the late Alexander Agassiz, the work of the International Commission for the Investigation of the Sea and the investigations of the fresh-water stations in Denmark, Germany, Switzerland and the United States have resulted in the perfection of instruments and methods and the accumulation of a mass of results. Steuer's treatise on planktology thus finds the time opportune for appearance and fittingly forms a volume in the

Teubner series ("Naturwissenschaft und Technik in Lehre und Forschung") under the editorship of Professors Doflein and Fischer, of Munich.

The first work is comprehensive in plan, covering all phases of the varied content of the subject of the life of the sea and of fresh water. The first chapter of the work deals with water, its distribution on the earth, chemical constituents, temperature changes, its relations to light and pressure, its color and odor, and its movements under meteorological influences. Other chapters treat of methods, quantitative, qualitative and statistical, of plankton investigations, of the adaptations of the plankton to flotation with special reference to viscosity in relation to temperature and season, of adaptations in color, and of phosphorescence.

It appears that the data cited by Steuer are quite inadequate to establish his thesis that the organisms of the plankton as compared with those of the bottom and shore are characterized by a relatively low rate of reproduction. It is not the pelagic nature of the organism which is the cause of the low rate of reproduction often observed in plankton-poor lakes but rather a poverty stricken habitat. The herring fisheries, the chalk beds of past ages, the abundant and rapidly fluctuating plankton of enriched rivers, the occasional sudden outbursts of the "mare sporco," all bear indisputable evidence of the capacity of pelagic life to respond to opportunities for rapid multiplication. This erroneous idea that the plankton has a relatively slight capacity for reproduction is correlated with another all too widely applied idea, namely, that the tropical seas are relatively barren. The facts are that fresh waters and the sea vary greatly in different regions and at different seasons in the amount of life they contain. In warm waters the chemical processes of life are so accelerated that life cycles are shortened and decay is hastened, while in colder waters growth and decay are slower and individuals accumulate though the total product in the two regions in a given time may be the same. Food supply and temperature affect

the rate and amount of reproduction in water as they do upon land.

The question of the biological stratification of the haliplankton is treated at length. Investigation has shown that the marine phytoplankton is mainly limited to a relatively thin superficial region about 200 m. in thickness and that it ceases to grow below 400 m. The zooplankton on the other hand descends, in the opinion of many investigators, to greater depths, feeding upon the debris of the phytoplankton and upon cadavers, descending from the more densely populated zone above. The *Valdivia*, which made but few hauls at great distances from continental influence or away from great currents, found evidence in closing net catches of animal life extending to great depths.

Steuer's presentation of Agassiz's results and conclusions in this contested matter is far from adequate. He designates the Pacific as "sehr planktonarme" and "wenig günstig" for the examination of this question of the extent of life below 400 fathoms. The plankton of the Pacific is certainly as rich in large areas and probably no poorer in others than that of other oceans, while the oceanic conditions it presents for investigation could hardly be more typical or more favorable for the determination of this question. Nor is Steuer's statement that Agassiz's admission of the existence of a true bathybiic plankton is to be accepted as placing him in accord with his opponents, to be regarded as either adequate or critical, for Agassiz limited this bathybiic plankton to regions of continental influence and to territories below richly laden currents. Furthermore, to characterize Agassiz's discoveries of so-called deep sea animals, such as *Pelagotheria* and fishes as "gelegentliche Auftretungen" of the bathybiic fauna in the upper levels of the sea is to dismiss a mass of evidence with a wave of the hand.

The horizontal divisions and the geographical and seasonal distribution of the plankton are discussed at length and its relation to the economy of nature and to man are analyzed. Under the latter caption attention is called to the relation of those occasional outbursts of

species resulting in discolored seas and disturbances in the balance of nature, to plankton as a source of food for man and for fishes, to pond culture, to purification of polluted streams, to fish culture, to plankton as an index of productive capacity of water, and to the relations of plankton organisms to education, research and the fine arts.

A compiled work of this sort, the first in its field, is necessarily incomplete and imperfect. Noticeable omissions in both works are the Lucas sounding machine, Whipple's thermophone, Nathanson's discussion of the relation of vertical circulation to the problem of maintenance of fertility of the sea, Pettersen's, Ekman's and Nansen's contributions to facts and theories of oceanic circulation, Bauer's work on vertical migrations, and, in general, an occasional lack of perspective in dealing with the results of Scandinavian, English, French and American literature of the subject—defects easily remedied in a new edition. Dr. Steuer has done a great service in putting in so concise and compact a form the most striking and many noteworthy achievements in the field of planktology. The illustrations are numerous, usually good and well-executed. Exception may be taken to inverted figures of *Ceratium* (p. 476) and to an inverted figure from Okamura of a crushed Peridinian labelled *Gonyaulax polygramma*. Much better figures of this species have long been available.

The second work is an abridgment of the first, omitting some of the illustrations, the extensive bibliographies and some of the more technical treatment of the chemistry and physics of water and some of the details of the discussion of the seasonal distribution of the plankton.

CHARLES ATWOOD KOFOID

UNIVERSITY OF CALIFORNIA

The Realm of Ends or Pluralism and Theism: The Gifford Lectures Delivered in the University of St. Andrews in the Years 1907-1910. By JAMES WARD, Sc.D. (Camb.), etc., Fellow of the British Academy and of the New York Academy of Sciences, Professor

of Mental Philosophy, Cambridge. New York, G. P. Putnam's Sons. 1911. 8vo. Pp. xv + 490. Price, \$3.00 net.

It was inevitable that the Gifford foundation for "natural theology" in the four Scots universities should produce some notable books, one or two bad books, and non-significant books not a few. Professor Ward's Aberdeen lectures of 1896-98, published under the title, "Naturalism and Agnosticism," have taken rank in the first class long since, as three editions attest. They embody a criticism of the Spencerian type of thinking, so astute and resourceful that, possibly, the assault need never be undertaken again. The present lectures are no less important, but, unlike their predecessors, they travel far from the beaten track of the "positive" sciences. It is the more necessary, then, to describe their contents fairly for readers of SCIENCE.

In the decade that has elapsed between the two courses, the fortunes of the "mechanical theory" have tended to sink lower and lower, so much so, that the spirit of revolt against it may be said to dominate contemporary philosophy, particularly in France, and this with scarce a protest, certainly with no effective protest, from the scientific camp; nay, if anything, with approval—witness McDougall's recent "Body and Mind." But, if the "mechanical theory" be thus relegated to the limbo of discards, we are confronted forthwith by a new situation. We must try "to ascertain what we can know, or reasonably believe, concerning the constitution of the world, interpreted throughout and strictly in terms of Mind" (p. v). Professor Ward's new work is a candid attempt to face this problem, and to think it through. Accordingly, its plan and main contents are as follows:

Part I. is a most adequate discussion of pluralism. After two introductory lectures (I., II.) and a discourse on the fundamental nature and contemporary ascendancy of this theory (III.), the author analyzes contingency in the world (IV.), evolution (V.) and the pluralistic goal (VI.). He then devotes two lectures (VII., VIII.) to Hegel—"it must be confessed, largely a digression" (p. vi). Part I. ends with critical treatment of the limits

and difficulties of pluralism (IX., X.), whence Part II., Theism, originates. "For pluralism, though empirically warranted, we find defective and unsatisfactory; but the theism to which it points is only an ideal—an ideal, however, that, as both theoretically and practically rational, may claim our faith though it transcend our knowledge" (pp. v, vi). Here Professor Ward plunges in *medias res* at once, with discussion of the idea of creation (XI.), and of the cosmology of theism (XII.). Investigations of freedom and foreknowledge (XIII., XIV.) follow. Lectures XV.-XVII. deal with the problem of evil in its relations to pessimism, optimism and the moral order. Lecture XVIII. presents theories of a future life and, as a pendant, we have a chapter on faith and knowledge (XIX). The concluding lecture, the Realm of Ends, is in the nature of a summary, and may be read as an introduction to the book. Twenty-seven pages of supplementary notes (on contingency, creation, the relation of body and mind, the temporal and the eternal, and the divine experience), and an adequate index, complete the volume.

In view of the subjects discussed, it is well, perhaps, to add by way of elucidation, if not warning, that Professor Ward has always kept in view the condition laid down by the founder. Lord Gifford's will contains this direction:

I wish the lecturers to treat their subject as a strictly natural science, . . . without reference to or reliance upon any supposed special or exceptional or so-called miraculous revelation. . . . They may freely discuss all questions about man's conceptions of God or the Infinite, their origin, nature, and truth, whether he can have any such conceptions, whether God is under any or what limitations, and so on.

This is precisely what Professor Ward has done; and, to quote the words of the first lecturer on the foundation, Max Müller, the book "must be reckoned among the signs of the times, pregnant with meaning." For it is the latest pronouncement, not simply of a veteran, but of one of the ripest and, from the scientific point of view, best equipped, among living thinkers.

Taking the work as a whole—for space forbids detail—the following remarks and excerpts may help to indicate its attitude and quality. Dr. Ward adopts the pluralistic position in pragmatic fashion. He insists that, as a matter of fact, we do start from a plurality of existing things. On the other hand, he nowhere affirms these things to be self-subsisting and, to this extent, leaves a convenient loophole. The most interesting result, from the scientific standpoint, is, possibly, the interpretation of evolution. "It is often applied to processes that are diametrically opposed, to the differentiation of a unity and to the integration of a plurality (97). . . . To the supposed unfolding of an organism regarded as completely pre-existing in miniature within the germ. . . . The successive unfolding of such a system, . . . though the *ne plus ultra* of evolution literally understood is then the direct negative of evolution as we understand it to-day. According to this later theory each new organism is not an 'educt,' but a 'product,' to use Kantian phrases: its *parts* are in no sense present in the embryo, but are gradually organized, one after another, in due order, as the term epigenesis implies and as Harvey, who first used the term, prophetically maintained (98). . . . It is the parts, the many, with which the pluralist starts: the question, whether or no there is an absolute whole prior to—at once the logical and the real ground of—all the parts, is for him not the first question but the last" (101). Plainly, the pluralist is tied to epigenesis: "The life-history of the race is original, is a long process of gradual acquisition by way of trial and error, in short, answers to what we have identified with *natura naturans*; whereas the genetic history of the individual is a derivative, rapid and, so to say, substantially invariable process, in a word, is routine or *natura naturata*" (207). Yet, even so, pluralism has its own difficulties. An "absolute plurality" "would be merely a sporadic manifold of realms of ends having a common physical basis but devoid of all teleological continuity (185). . . . A Supreme Spirit con-

fronted and conditioned by free agents certainly does not correspond to the notion usually entertained of the Deity. Such a 'finite God' many would disown as a manifest contradiction in terms; yet beyond this it does not seem possible for the pluralist to go" (194). Nevertheless, pluralists would deny that evolution requires a transcendent Prime Mover distinct from the Many: for the Many they hold are all prime movers, and so far *causa sui*. . . . The efficient causation in the world then is just this totality of prime movers, its final causation their organization into a higher unity" (199). That is to say, singularism, with its Absolute, is not the sole alternative; nor is scepticism the consequent recourse; therefore the contradictions as between the One and the Many remain to be overcome. The lectures on Theism offer the solution, or considerations towards it.

Theism "introduces one essential modification, at any rate, viz., the idea of creation. It does not, that is to say, assume merely that one transcendent Being exists above and beyond the whole series of the Many, however extended; but it assumes further that this one Being is related to them in a way in which none of them is related to the rest: they do not simply coexist along with it, they exist somehow in it, and through it" (231). This implies the difficulty, admitted to be insuperable (245), of the self-limitation of Deity. Hence, turning again to experience, "between the intemporal world of ideas and the temporal world of phenomena, free agents have their place" (306). Accordingly, the ideal realm of ends is "the achievement of virtuous struggle crowned eventually with victory" (374). Consequently, as to immortality and faith, "death becomes indeed but a longer sleep dividing life from life as sleep divides day from day; and as there is progress from day to day so too there may be from life to life (407). . . . Hence the moral ideal, as it leads to faith in God, leads also to the belief that the spirit world has other dimensions than those of the time and space that encompass the world of phenomena. . . . Has not God been mocked and life called the vanity of

vanities on the assumption that the present world is all?" (429).

Despite my radical dissent from Dr. Ward's pluralism, with its concessions to what I am bound to call irrationalism, his book has made a profound impression upon me. It is a work which any man may well peruse as a discipline in self-education, and this without reference to the field of his specialty. Assuredly, we have to thank Dr. Ward for a human, and therefore significant—often a wise—pronouncement. A main portion of the charm of the work is traceable to the skill shown by the author in conferring distinction upon the commonest things.

R. M. WENLEY

ANN ARBOR

BOTANICAL NOTES

THE PASSING OF THE SLIME MOULDS

DE BARY, whose keen botanical perception has perhaps never been equalled, long ago discarded the name *Myxomycetes* for the slime moulds, significantly applying to them the name *Mycetozoa*, and then placed them outside the limits of the vegetable kingdom, greatly to the consternation and indignation of many fungologists of the old school. The latter, relying upon external characters, associated them for a long time with the puff-balls among the higher fungi, implying a relationship whose impossibility is now manifest to the merest tyro in botany. Latterly they have been pushed down into the neighborhood of the schizophytes (blue-green algae, and the bacteria), as is done by Engler in his "Syllabus," but he takes particular pains to disclaim any relationship with the true fungi (*Eumycetes*), or higher plants.

More than thirty years ago the writer of this note said of them "they have no structural affinities with plants higher than they are, nor with any lower; they stand alone, and appear to belong to a different genetic line" ("Botany," p. 207), although in deference to the views as to their nature then prevalent they were still included among plants. By speaking of them as "a group of remarkable organisms which differ in many respects from

all other vegetable structures," and by comparing them to certain Protozoa the attempt was made to educate the reader to regard them as aliens instead of true plants. In later publications they have been omitted as no longer necessary to be spoken of in a systematic arrangement of plants.

The final disappearance of these animals from the domain of botany seems now imminent, for in the new (eleventh) edition of the *Encyclopaedia Britannica* they are treated under De Bary's name of *Mycetozoa*, with the introductory defining phrase "in zoology, a group of organisms reproducing themselves by spores." The whole treatment, which is by J. J. Lister, is zoological, and no doubt is expressed as to their animal nature. We may now look for an approaching general revision of our botanical text-books so as to omit the *Mycetozoa*, greatly to the relief of the scientific botanists who have long been sorely puzzled to find a proper niche in which to fit them in the vegetable kingdom.

It will now be necessary for the zoologists to prepare to take charge of the considerable number of *Mycetozoa* to which they fall heir. It behooves the botanists to generously remove the specimens of these organisms from the pigeon-holes of their herbaria, and turn them over to the zoologists to be placed by them on the museum shelves devoted to the *Sarcodinia* among the Protozoa. And further it will become necessary for the librarians to revise their system of classifying botanical and zoological books so as to make the proper transfers upon their shelves and in their card catalogues. When all this is done the botanists may feel that they are well rid of these animals that have too long roamed quite too freely in the botanical garden. The "slime moulds" will have passed from the domain of botany, and there will remain in their stead only the "fungus animals."

THE SECRET OF THE BLUEBERRIES

IF to make "two blades of grass grow where but one grew before" has been regarded as a laudable undertaking, what shall we say of the successful effort to make blueberries grow

where they would not grow at all, and yet this is what F. V. Coville, the government botanist, seems to have done. In an interesting bulletin (193) of the Bureau of Plant Industry of the U. S. Department of Agriculture which appeared a little more than a year ago, Mr. Coville shows that blueberries (mainly of the species *Vaccinium corymbosum*, known as the swamp blueberry) differ from many ordinary plants in their soil requirements, and with the knowledge thus attained he has worked out a system of culture that promises to result in their successful culture. In the course of his paper it is shown that the swamp blueberry "does not thrive in a rich garden soil," nor on "heavily manured soil," and so for soil treated by lime, heavy clay soil, ordinary leaf mold soil, or any soil with a neutral or alkaline reaction. On the contrary, it is shown that it requires an acid soil, such as afforded by peat.

Applying these facts, Mr. Coville has successfully grown many plants of the swamp blueberry in pots, and their robust growth affords good promise of success in the field. The investigation with pot cultures is to be followed with those in the field and in this considerable progress has been made. "There is good prospect that the application of the knowledge thus gained [from the pot cultures] will establish the blueberry in field culture, and that ultimately improved varieties of these plants will be grown successfully on a commercial scale."

THE GRAMA GRASSES

DAVID GRIFFITHS has rendered a good service to students of the grasses by the publication of his paper on "The Grama Grasses" (Contrib. U. S. Nat'l Herbarium, Vol. 14, pt. 3, 1912), in which he describes the species (46) included in the genus *Bouteloua* (36), *Cathestecum* (4), *Pentarrhaphis* (2), and *Triaena* (1). By means of good figures the details of the spikelets are made plain, and these are supplemented by full descriptions, and a citation of specimens in the National Herbarium. The synonymy of these species

is given very fully with critical notes. From this portion of the paper we learn why the more common species now bear the names *Bouteloua hirsuta*, *B. gracilis* (instead of *B. oligostachya*), and *B. curtipendula* (instead of *Atheropogon curtipendula*). One new species of *Cathestecum* and two of *Bouteloua* are described.

In speaking of their economic importance the author says: "It is doubtful whether there is another group of native pasture grasses which is of as much economic importance as this when both quality and quantity are considered." "The most promising of all the species for field cultivation is *B. curtipendula*, not that it grows any more readily than the others, but on account of its size and habit." "*Bouteloua gracilis* makes a splendid turf when sown thickly and well cared for." However, on account of the difficulty in collecting seed he has to say at last that "in short, it is more than probable that because of the lack of good seed habits in this genus, even the most valuable species can not become of importance in cultivation."

BOTANICAL NOTES

A NUMBER of papers on the fungi should be noted here—the first, by W. C. Coker and Louise Wilson (in *Mycologia*, November, 1911), on a curious "conjugating yeast" (*Schizosaccharomyces octosporus*) in fermenting grapes, in which the plants multiply vegetatively not by budding, as in other yeasts, but by fission. The "conjugating" cells constitute "a double sac that resembles a pair of saddle-bags" and in this structure eight spores are produced.

The "Experiments on Spore Germination and Infection in Certain Species of Oomycetes" (Research Bull. 15, Wisconsin Experiment Station) by I. E. Melhus, are concerned with the White Rust of Crucifers (*Cystopus* (*Albugo*) *candidus*). It was found that the spores germinate best in water and rather low temperatures, and that plants are more easily infected at low temperatures, also, probably "due to the increased percentage of spore germination."

DR. RICHARD DE ZEEUW publishes a helpful paper in the *Centralblatt für Bacteriologie, Parasitenkunde und Infektionskrankheiten*, 1911, on the "Comparative Viability of Seeds, Fungi and Bacteria when Subjected to Various Chemical Agents," in which he shows that the disinfection of seeds, etc., is by no means as easily accomplished as has been supposed, and that the results of many experiments requiring disinfection are open to criticism.

We can not pass by without at least brief mention the *Journal of the College of Agriculture of the Imperial University of Tokyo* (Japan), in the December number of which are two articles by Professor Dr. S. Kusano, the first, on "*Gastrodia elata* and its Symbiotic Association with *Armillaria mellea*," showing that this chlorophyll-less orchid lives in a beneficially symbiotic relation with the mycelium of the fungus. The second paper, "On the Root-Cotton, a Fibrous Cork Tissue of a Tropical Plant" (*Fagara integrifolia*), shows that "the root-cotton is a kind of cork tissue derived from the cork cambium, which arises primarily from the pericycle or secondarily from the bast of the root." The author concludes that it is of economic value, "chiefly in its unwettable and less hygroscopic quality." The papers are illustrated by seven very fine plates.

CHARLES E. BESSEY

THE UNIVERSITY OF NEBRASKA

THE RELATION OF PIGMENTATION TO TEMPERATURE IN DEEP-SEA ANIMALS

PROFESSOR C. V. BURKE's article on the relation of color of certain sea-animals to the depth at which they live¹ is of much more than ordinary importance, for it may be possible to coordinate these facts with similar ones as to tropical land animals which show that pigmentation is of great, if not vital importance in heat regulation. In nearly all the biological literature on the subject, it is assumed that the sole use of pigment is for concealment by

more or less resemblance to something in the background or to the background itself. This may be true of all colors but pigment of any color, if opaque enough, may protect underlying tissues from death due to excessive light, a matter to which von Schmaedel first called attention as to man, nearly twenty years ago. This rule has now been found to be universal, for in every species there is a pigment or other protection proportionate to the intensity of the light. In the 1887 *Proceedings of the Royal Society of Edinburgh*, Dr. Robert Wallace, now professor of agriculture in the University of Edinburgh, published another epoch-making observation, which, like that of Mendel and of many others, was completely ignored for a quarter century. Wallace found that all the domestic mammals of the tropics had black skins, and though Huxley was much impressed by the universality of the phenomenon, he could suggest no reason for it because up to the time of his death very little was known as to the deadliness of the shorter ether waves to all naked living tissues, such as in the case of bacteria for instance; and though we then used sunlight to "disinfect," by killing our parasites, no one had yet perceived that it could also kill us. It is now known that the main purpose is light protection, and there is a wealth of evidence that if unpigmented stock is taken from dark climates to light ones it dies out. The agricultural experimenters have utterly failed to establish the big white swine in our west or in any light climate and at the present moment, in many parts of the world, farmers are vainly trying to breed imported stock insufficiently pigmented. The matter is of such great practical importance that it must be cleared up at once to stop the present wasteful methods.

It has also long been known that black assists heat radiation in all temperatures below body heat. These black-skinned domestic animals are then the fittest for tropical temperatures, but they can not expose themselves to the sun because of the fatal absorption of heat. They instinctively hide in the day, if the skin is not covered by a reflecting coat as in the Arab horse. In cold light countries

¹ SCIENCE, October 6, 1911.

excessive radiation is prevented by fur and hair, as in the black skinned Mongolian pony. The black skinned animals with little or no hair are therefore restricted to a very limited thermal range, while those with hair or fur protection are healthy in all extremes.

Some recent observations of horses in the Philippines, Japan and Korea have shown that slight differences in climate make great differences in hair color and it seems to depend more largely on air temperature than was formerly thought. The detailed data were published in a preliminary article in the September number of the *U. S. Cavalry Journal*, but the point of present interest is the relation of pigment to the environmental temperature.

Every kind of protoplasm has a very limited thermal range in which it functions best; in some cases there is practically no range at all for the function is disturbed by even a half degree of change. Every kind of protoplasm can live if subjected to higher or lower temperatures than its optimum even if it ceases functioning. But it is to be noted that no kind can stand very much rise of temperature, though it may be chilled to the absolute zero for a short while. The upper thermal death point is therefore so near the usual range and the malfunctioning due to any rise is so great, that each species adopts some safeguard against overheating. In the land mammals it is always some method of radiation or evaporation of perspiration and a dark color seems vital for the purpose of radiation in all temperatures below body heat. It is amazing to see the differences in horse colors in different localities according to temperature in Japan, Korea and wherever there has been no check to the process by importations for some centuries. Where there is heat to reflect at any season the color is light or white.

One of the puzzles of zoology has been to account for dense pigmentation where there is very little light. If there is complete darkness, as in some caves, the color of fishes is apt to disappear entirely by selection on the ground of economy, the pigment evidently being an expensive drain on the resources. As

fish are said to have a temperature but little above that of the water in which they live, there is evidently little or no need for them to have safeguards against overheating or chilling in a medium, never hot enough to be injurious nor below 40° F. as a rule. Hence coloration of fishes has been invariably interpreted as for concealment, and the facts certainly do point to that reason.

In the deep sea, on the other hand, we have vastly different conditions. The only light is a phosphorescence which is usually so faint as to require very large eyes, yet some investigators assure us that it can be so intense as to demand dense pigmentation for concealment. This may account for the fact that the pigment is often spread all over the body, as would be necessary if the light comes from all directions and not always from above, as in the fishes of the upper layers. Yet there are curious exceptions, as though some deep sea places were as dark as caves, for some species have little or no pigment and some have no eyes; but as far as known, the relation between these facts, if there is any relation at all, has never been explained or proved.

With regard to deep sea temperatures we are assured that generally they are very low, specimens being too cold to handle. Salt water at such pressures can be much below 32° F. without freezing, and it is often found at a degree which prevents all activity of fish in surface waters. They "hibernate" in such chilly surroundings. There must then be a different law as to the relation of the body temperature of deep sea fish to the water surrounding them. All the mammals of the sea are densely pigmented and generally all over. They are never subjected to high temperatures nor to anything lower than 32°, and have no need for protection from extremes. The pigment then must be for light protection. They all prevent undue heat loss by the thick layer of insulating fat, so the radiation of heat by the black color can do no more harm than in the case of black cattle which are found in mild temperate climates. Black pigments can not be for the purpose of absorbing heat from the sun's rays, for all such animals avoid the

sun, nor can sea-mammals absorb to any extent that way as the heat does not penetrate enough. The surrounding medium is always below body temperature and the heat flow is always from the body not into it. As all mammals seem to depend upon more or less constant loss of superfluous heat by radiation and much loss during exertion, the black colors are probably of as great use to whales and porpoises, as to elephants and similar hairless tropical animals who likewise are never exposed to extremes and whose ranges of temperature do not differ markedly from those of the sea mammals. That is, there must be, as in horses, some means of preventing overheating, and color surely helps according as the animal is shaded or exposed to the sun. The amazing differences in horses can be logically explained on these lines, as seen in the above paper. Hence there is a suspicion that dark color in all sea-fishes at any depth has some unknown relation to the temperature, as well as the need of concealment. It must be remembered that the inner surfaces of shells, and the concealed surfaces of some parts of the bodies of many animals are most unaccountably pigmented. Neither the food nor protection from light nor resemblance to the background can be the reason, nor can it be a vestige of a previous useful condition. Indeed it is a puzzle which needs explanation, and it is requested that in all future studies there be facts presented as to the temperature of both the water and the body of the animal. It is not likely that the deep-sea fish can function at such low temperatures as we are told do exist, and it is probable that we shall find that where life is abundant the temperature of both fish and water is considerably above 40° but that in the vast areas where no life at all is found the cold may be the prohibitive factor. There must be as great variation from place to place by reason of currents as in the air. The prevalent winds make only a few degrees difference between the temperature of the northeast and southwest of Japan, but the horses in the first place are dark brown and in the latter light yellow for this reason alone. There must be similar local differences

in the deep sea, due to currents to account most fully for differences in pigmentation. If the color darkens with increasing depth and coldness, then the animals surely lose by radiation what little heat they have and must be unable to function at all. Unless, then, there are different laws for the deep sea life, of which we can not conceive at present, there must be another reason for a concealing blackness which would be a fatal radiator to ancestral types nearer the surface. Indeed there may be some unknown laws of heat radiation under such tremendous pressures, which actually reverse matters and make the pigment a conservator of body heat in cold water. It can scarcely be believed that the color is to help absorption of heat, for there is little to be absorbed—the animal must depend on its own heat production. That is, the facts so far known do not explain the blackness of the deep sea fish.

CHAS. E. WOODRUFF

PHYSIOLOGICAL SEX DETERMINATION

AN interesting, if not convincing, collation of arguments in support of the notion that the suprarenal capsules are concerned in determining the sex of offspring was presented to the Paris Academy of Sciences on November 20, 1911, by Dr. R. Robinson. His arguments fall into three groups.

1. *Clinical observations.*

It has been shown by Dr. Fieux Agregi, of Bordeaux, that when the heart-beat of the fetus is between 136 and 150 per minute there is born a female in 68 per cent. of the cases; if the heart-beat is more than 150 it is always a male. He had fifty cases. Robinson not only confirmed Agregi's observations, but was able to determine the retarding action of the administration of adrenalin upon the pulse of the fetus. He therefore presumes that if this substance were administered from the early days of pregnancy it would influence the heart-beat and so the sex of the fetus.

2. *Anatomo-physiological facts.*

The adrenal glands seem to influence the development of the individual after birth, if they do not cause the determination of the

sex immediately after conception; this is shown by their relations to some of the secondary sexual characters. In England a woman of 32 years who had never menstruated, had hair on face, etc., and other appearances of a man; an autopsy showed the presence of large tumor on the suprarenal. Bortz, the German surgeon, observed a girl of 16 who took on the characters of the male—beard, deep voice, distribution of hair on body, etc. Post-mortem examination showed tumor on suprarenal. A woman of 26 years was observed by a Dutch physician: she was obliged to shave like a man. Autopsy showed one of the suprarenals enclosed within the ovary. Similar facts have been published by many physicians.

3. *Chemical reactions.*

Is there any means, asks Robinson, of knowing approximately the functional state of the suprarenal capsules in the gravid female? This is worth studying if we are to come to an understanding of sex determination. Violent or obstinate vomiting and other symptoms of suprarenal insufficiency are not constant in their manifestations. He therefore used the Fränkel-Allers test (acid iodate of potassium) to reveal the slightest trace of adrenalin in the urine or blood. He used also the method of Vulpian (perchloride of iron); but found the per-iodate of potassium much more sensitive and certain in its reactions. By these means he foretold the sex of a fœtus in the fourth month.

From all these facts he thinks it is safe to conclude that the adrenalin influences the sex of the developing embryo, at least in the higher vertebrates or in man.

The hypothesis that adrenalin influences the heart-beat has been subjected to experiment and has been confirmed; but the hypothesis that the rate of the heart-beat determines the sex is one that may be tested experimentally, but has not yet been so tested. It is interesting to note that in the clinical observations given by Robinson the heart-beat of the male is higher than that of the female; this is contrary to the commonly accepted relation. The argument, moreover, may prove too much. If

maleness is converted into femaleness by the adrenalin directly, or indirectly through the influence of this upon the circulatory system, it should be possible to bring on secondary female characters in a male by the administration of adrenalin before or at puberty.

The number of cases in which the sex was foretold on the basis of the Fränkel-Allers test for adrenalin in the blood or urine is not given by Robinson; presumably too few to warrant statistical conclusions. But even if the number were very large, and even if there should be found a constant relation between the sex of the fœtus and the quantity of adrenalin produced in the pregnant mother, these facts would by no means indicate a causal relation in the sense assumed by Robinson. It is quite conceivable that, in the case assumed, the physiological state of the fœtus determines the activity of the mother's adrenal capsules.

A more general criticism of Robinson's argument lies in the tacit assumption that sex differentiation means one thing in the higher vertebrates and man, and quite a different thing in the rest of the animal kingdom and in plants. It may well be that there are several distinct factors concerned in sex determination, but these must all belong to related categories. It is extremely improbable that sex is determined by an accessory chromosome among insects, by adrenalin among mammals, by traumatism among graminæ, say, and by ultra-violet rays among mosses. It is interesting to note, in conclusion, that physicians have formulated several theories of sex determination in recent years, but always in complete innocence of the work being done by experimental biologists along this line.

SOCIETIES AND ACADEMIES

THE AMERICAN MATHEMATICAL SOCIETY

THE one hundred and fifty-seventh regular meeting of the society was held at Columbia University on Saturday, February 24, extending through the

usual morning and afternoon sessions. The attendance included forty-one members. President H. B. Fine occupied the chair. The council announced the election of the following persons to membership in the society: Mr. J. W. Alexander, Princeton University; Mr. A. A. Bennett, Princeton University; Professor J. G. Coffin, College of the City of New York; Professor G. H. Cresse, Middlebury College; Mr. C. R. Dines, Dartmouth College; Professor H. E. Jordan, University of Kansas; Mr. F. S. Nowlan, Columbia University; Professor C. W. Watkeys, University of Rochester. Eight applications for membership in the society were received.

Announcement was made of the gift of Dr. Emory McClintock, second president of the society, of over four hundred valuable books to the library. The gift also includes a large number of pamphlets and reprints of important mathematical papers.

The following papers were read at this meeting:

S. A. Joffe: "Sums of like powers of natural numbers."

G. A. Miller: "Second note on groups generated by operators transforming each other into their inverses."

S. Lefschetz: "On remarkable points of curves."

S. E. Uner: "Certain singularities of point transformations in space of three dimensions."

A. B. Coble: "The characteristic theory of the odd and even theta functions as related to finite geometry."

H. H. Mitchell: "Some quaternary groups with particular prime moduli."

J. E. Rowe: "The undulation and cusp invariants of the R^n ."

W. F. Osgood: "A necessary and sufficient condition that a single-valued function in a projective space be rational."

Dunham Jackson: "On the convergence of the development of a continuous function according to Legendre's polynomials."

K. P. Williams: "The solution of non-homogeneous linear difference equations and their asymptotic forms."

E. J. Miles: "Note on the isoperimetric problem with discontinuous integrand."

Dunham Jackson: "On approximation by trigonometric sums and polynomials."

J. E. Hodgson: "Orthocentric properties of the plane directed n -line."

The date of the next regular meeting of the society falls on April 27. The Chicago Section

and the San Francisco Section will both meet on April 6.

F. N. COLLE,
Secretary

THE AMERICAN CHEMICAL SOCIETY NEW YORK SECTION

At the meeting held at Rumford Hall on March 8 the following sectional officers were elected to take office at the close of the present session in June: *Chairman*, Arthur B. Lamb; *Vice-chairman*, David Wesson; *Secretary-Treasurer*, C. M. Joyce; *Executive Committee*, A. C. Langmuir, G. A. Hulett, Allen Rogers and T. L. Briggs.

The Wm. H. Nichols medal (for the session of 1910-11) was awarded to Professor Charles James, of New Hampshire College, for his work on the rare earths.

Dr. W. Gilman Thompson read a paper on "Occupational Poisoning in Chemical Trades."

This paper awakened considerable interest and discussion, the meeting favoring further investigation of the subject and appointing a committee for this purpose.

Dr. A. M. Comey read a paper on "The Testing of High Explosives," illustrated by slides, and Mr. A. E. Marshall spoke on "Silica Ware: Its Manufacture, Properties and Uses."

C. M. JOYCE,
Secretary

THE NEW YORK ACADEMY OF SCIENCES SECTION OF BIOLOGY

At the regular meeting of the Section of Biology, held at the American Museum of Natural History, December 11, 1911, Chairman Frederic A. Lucas presiding, Professor Henry E. Crampton gave a lecture, illustrated with lantern slides, on his recent explorations in Guiana and Brazil. Dr. W. K. Gregory concluded his communication on the "Origin of Paired Limbs," reviewing the rival claims of the Crossopterygii and Dipnoi for the ancestry of the Amphibia and reinterpreting the elements of the pectoral limb of the Upper Devonian Rhizodont genus *Sauripterus*.

At the regular monthly meeting of the section held at the American Museum of Natural History, January 15, 1912, the following papers were read: *Phylogeny and Ontogeny of the Horns of Mammals*: HENRY FAIRFIELD OSBORN.

The recent discovery of the modes of origin of the horns in the titanotheres, a perissodactyl group remotely related to horses, tapirs and rhinoceroses, permits of a comparison of phylogenesis with the ontogenesis of the horns in bovine mammals. The

latter is based upon an osteological series recently prepared by Mr. S. H. Chubb, the former is based on the rich phylogenic series of Eocene titanotheres in the American Museum of Natural History. The conclusion is that ontogeny closely recapitulates phylogeny, that the genesis is gradual or continuous, that the horns arise definitely and determinately. In the bovine series it seems, in accord with the conclusions of Dürst, that the horn first appears as a circular thickening of the skin, accompanied by accelerated growth of the hair preparatory to the formation of the keratin of the horny substance, at a period considerably prior to any sign of the horn in the bony structure of the frontals. This raises the problem, which will form the subject of a special paper in the *Annals* of the Academy, as to what element first arises in connection with horn evolution, namely: (1) the psychic, or desire to use the horn, (2) the epidermal callous or keratin protection of the bony horn center, or (3) the bony or osseous horn itself. It would appear that the psychic tendency must precede the epidermal and that the latter precedes the osseous, but this disputed point requires further investigation.

Skull Measurements in Man and the Hoofed Mammals: HENRY FAIRFIELD OSBORN.

Comparative anatomists and zoologists have been slow to introduce into mammalogy systems of measurement by indices and ratios, which have proved of such universal value in anthropology. It is found among the hoofed mammals, from studies undertaken by the author with the cooperation of Dr. W. K. Gregory, that *cephalic indices and limb ratios* between different segments of the skeleton are far more significant than systems of direct measurement. These cephalic indices of the gradual changes of proportion between different regions of the skull have the value of specific characters and sharply distinguish members of different phyla. For example in the cross between the horse (*E. caballus*) and the ass (*E. asinus*), it is found that the cephalic indices are transmitted as pure non-blending characters.

Among the most significant indices are the following: (1) the cephalic, which is obtained by dividing the total or basilar length of the skull by the zygomatic breadth; (2) the cranial, which is obtained by dividing the basilar length by the postorbital length of the skull; (3) the facial, obtained by dividing the basilar length by the preorbital length of the skull, etc. The horses show proopic dolichocephaly, or elongation of the face,

and a static condition of the cranium, while the titanotheres, in contrast, show opisthopic dolichocephaly, or elongation of the cranium, and abbreviation of the face. Like the phyletic differences of proportion between the horse and the ass, these differences are most exactly expressed by the method of indices.

The application of the ratio method to the limbs of the hoofed mammals has again produced most surprising results. It is found that mammals of different phyla adapted either to "weight" or to "speed" converge respectively toward typical "weight" or "speed" ratios, which are obtained by dividing the length of the lower segments, tibia and radius, respectively, by the upper segments, femur and humerus, metacarpus and metatarsus, respectively. These "weight ratios" and "speed ratios" are far more significant as regards function and phyletic change than the actual or direct measurements.

This subject will be fully treated in the author's forthcoming monograph "The Titanotheres," to be published by the United States Geological Survey.

Whaling in the Olden Time: FREDERIC A. LUCAS.

The speaker exhibited lantern slides illustrating some interesting pictures from old works on whaling and showing the methods practised by the early Japanese, European and American whalers.

At the regular monthly meeting of the section, held at the American Museum of Natural History, February 12, 1912, Professor Bashford Dean presiding, the following paper was read:

Some Factors of Geographical Distribution in South America: JOHN D. HASEMAN.

The speaker outlined his itinerary in Central South America, where he had spent the years 1907-1910 collecting fishes, etc., for the Carnegie Museum and studying the geology, physiography and faunal complexes. He criticized the "static method" of studying geographic distribution as leading to no certain results. He outlined his conception of the geology and former topography of South America as bearing upon the problems of distribution and as being distinctly unfavorable to the "Gondwana land" hypothesis. He also analyzed the faunal similarities between South America and Africa and held that they offered no valid evidence for the former existence of a land bridge between those continents. His results are being published in the *Annals* of the Academy.

WILLIAM K. GREGORY,
Secretary

THE knowledge of breeding has advanced so rapidly in recent years that few of us realize the great change that has taken place in our understanding of the fundamental principles, and the effect that this change has had on the methods of practical breeding which we advocate. I had the good fortune to begin my studies and experiments in breeding in 1890, ten years before the rediscovery of Mendel's now famous principles of heredity, or the publication of de Vries's mutation theory. I have thus had the opportunity to follow this change through all its ramifications. From a condition of ignorance and largely of chaos, where all advance was taken as a lucky chance, we have developed to a position where practically each step may be taken intelligently. True, we touch the limits of knowledge on every hand and many of the most fundamental problems still remain unsolved, yet our understanding to-day, which enables us to analyze a plant into its component parts or characters, and then in turn by synthesis to build up a new structure by the combination of different characters into a new race or variety, is to our former understanding as light to darkness. The knowledge of breeding has developed into the science of genetics, and is fast assuming through the orderly presentation and classification of facts, the form of an exact science. Yet with all this advance in our understanding,

¹Paper No. 27, Department of Plant Breeding, Cornell University, Ithaca, New York. Annual address of retiring chairman of the Plant Section, American Breeders' Association.

the methods of breeding that can be recommended for the use of practical breeders have changed but little in the last twenty years, the greatest change being primarily in the greater surety with which we now make recommendations. It is the speaker's purpose in this address to emphasize certain salient features of the advance that has been achieved, and point out what he conceives to be some of the most important problems awaiting solution.

Twenty years ago our understanding of the principles of breeding was derived largely from Knight's physiological papers and Darwin's "Origin of Species" and "Plants and Animals under Domestication." Verlot's admirable pamphlet "On the Production and Fixation of Varieties of Ornamental Plants" gave a general outline of the best methods then followed, and we derived our knowledge of the use of hybrids largely from Focke's excellent text, "Die Pflanzenmischlinge," published in 1880, and the work of the French experimenter Naudin.

At that time breeders clearly understood the fact that hybrids segregated in the second generation and gave new combinations of characters, and the suggestion was even then present in the minds of scientific breeders, that this segregation of characters took place during the reduction division. At that time breeders, just as definitely as now, planned experiments in hybridizing different varieties or species to secure certain recombinations of desired characters in the hybrids. The experiments in citrus hybridization conducted by Mr. W. T. Swingle and the speaker were planned in 1893 entirely on this basis, yet the principle was in no sense of the word original with us, but was at that time well understood by all practical breeders. This understanding, the speaker thinks, was largely derived from the investigations of

Naudin, though various investigators contributed to it.

With a full understanding of the knowledge and practises of the breeders of two decades ago, it must be admitted that the conception of unit characters and Mendelian segregation was necessary to clarify this knowledge and bring out the latent possibilities of the material presented by nature for the use of the breeder, and it is doubtful whether we even yet adequately comprehend the almost infinite possibilities open to us.

To understand breeding to-day we must clearly understand the conception of unit characters. We no longer conceive the species, race or variety, as a fixed ensemble of characters. Following De Vries, we now commonly conceive the species or variety to be made up of a certain number of unit characters, that are in large measure associated together by the accident of evolution or breeding and which are separable entities in inheritance. We may liken these unit characters to bricks used in the construction of a building, each separate and yet dependent on the others for the maintenance of the structure; as each unit character is dependent on the other unit characters for the maintenance of the plant body. We may think of these unit characters as organic elements similar to chemical elements, that by their recombination through hybridization, form new compounds—new plants—of distinctly different appearance, but which in turn do not affect the unit characters, which may again be separated and led to form other compounds, again resulting in distinct organisms. Related species may possess many distinct unit characters, but ordinarily would be expected to possess many similar unit characters. Cultivated races or varieties ordinarily would differ only in a few unit characters, and difference in a

single unit character would be sufficient to give a distinct and recognizable race or variety. Indeed, the difference between two varieties of a single unit character might mean that one variety would be exceedingly valuable and the other practically worthless. De Vries asserts that unit characters are discontinuous in inheritance and do not exhibit transitional forms. A plant can not be hairy and at the same time smooth, or a fruit yellow and at the same time red. While there is yet much difference of opinion on these questions the preponderance of evidence certainly favors the unit character conception.

If, then, we recognize that species are made up of unit characters and that different species differ in the possession of different unit characters, the great problem in the evolution of species becomes the question of how the new unit character is acquired. Have all unit characters existed from the beginning, or are new unit characters being continuously acquired? A few years ago we supposed that new characters, if acquired in any form, must be seized upon, as it were, by natural selection and preserved, or otherwise that they would be swamped by intercrossing and lost. We now know from Mendelian analysis that a unit character may be apparently lost in crossing, owing to the prevailing presence of its dominant allelomorph, but that in reality it is not lost or apparently changed and will reappear again when it happens that two gametes both bearing the character meet in fecundation. It may remain hidden for many years, but as we are now inclined to view the matter, the character or the determiner of the character would not be permanently lost to the species unless all individuals possessing it were killed before they produced seed. This unit character idea would lead us to the conception of the species as made up of all the unit char-

acters that it has acquired by any means in its development and which still exist. The acquirement of any new unit character would add one more character to the species and double the number of possible varieties or races of the species.

In evolutionary studies we have long recognized that variation was the foundation of evolution and that no evolution was possible without variation, but we have assigned to selection an all-important part as guiding and even stimulating the variation in a certain direction. Darwin and particularly some of his more radical followers have assigned to selection a creative force, in that it has been assumed that when nature by a slight variation gave the hint of a possible change in a certain direction, natural or artificial selection, by choosing this variant and selecting from among its progeny the most markedly similar variants, could force the advance of the variation in the direction indicated. Since Darwin's time this cumulative action of selection has been emphasized so forcibly that we had come to recognize selection as an active forge in creation rather than simply as a selective agency. To be the vital principle of evolution, as we now understand the species as made up of heritable unit characters, the selectionist must show that a new character can be created by selection, otherwise selection becomes a secondary principle.

When viewed from the standpoint of the production of a new and definitely heritable unit which mendelizes, the task of selection becomes more doubtful. Darwin's idea, that changes in species required many years and probably many centuries for accomplishment, took the subject largely out of the field of experimentation and in a measure developed a speculative science. One of the greatest contributions to science made by De Vries was to estab-

lish the study of evolution on an experimental basis. With the demonstration that evolution could be studied experimentally, the question of the effectiveness of selection was taken up, and we are now doubtless on the road to a solution of the problem. It is only possible for us here to call attention to a few of the researches in this direction.

The classical researches of De Vries, now familiar to us all, challenged the correctness of the selection theory and sought to show that species originated by sudden jumps or mutations. We may admit that De Vries proved that species or new characters were formed suddenly as mutations, but this would not prove that they might not also be formed or actually induced to mutate by a continuous process of selection. Indeed, in his experiments on the production of a double-flowered variety of *Chrysanthemum segetum* ("Mutationstheorie," Vol. I., p. 523), a few generations of selection led to markedly increasing the number of ray-florets before the ligulate corollas appeared among the disk-florets, the change which he interpreted as the mutation that gave him the double variety.

Johannsen has contributed much to our knowledge of selection and has given us a more exact method of experimentation by his conception of pure lines, biotypes, genotypes and phenotypes. His experiments in the selection of pure lines of beans in an attempt to produce large and small seeded types, have led him to conclude that selection within a pure line is ineffective in producing changes. He did, however, secure new types from pure lines through mutations.

Tower's experiments with the potato beetle in attempting to create by selection, large and small races, albinic and melanic races, and races with changed color-pattern, although conducted carefully for from ten to twelve generations, failed to

give any evidence of producing permanently changed types. While strains of plus and minus variates gave populations with a range of variation apparently markedly restricted to their respective sides of the normal variation range, still these selected strains did not greatly exceed the normal range of variation in either direction, and when the selection was discontinued, in two or three generations, again produced populations exhibiting the normal range of variation. Clearly no new unit characters had been added by the selection. Tower, however, found that by subjecting the beetles, during the process of the formation of gametes, to certain abnormal conditions, he was likely to obtain mutations in the progeny that would immediately form the beginnings of new races.

Jennings in a series of selection experiments conducted with paramecium, which were continued for over twenty generations, obtained no evidence of a permanent modification of the type.

Pearl has conducted an extended experiment in the selection of chickens in the attempt to produce a breed of high egg-laying capacity. His results have led him to the conclusion that selection alone has no effect in producing a permanent improvement or a change of type.

Up to the present time these are the principal contributions to the subject, that discredit the effectiveness of selection as an active agency.

On the opposite side of the controversy we have the very careful and extensive researches of Castle and MacCurdy in the selection of Irish rats to increase the black-colored dorsal band on the one hand and to decrease or obliterate it on the other. Castle appears to have obtained very positive results favoring the gradual cumulative action of the selection, as he succeeded in markedly increasing the amount of black

in one strain until the rats were almost wholly black, and in the other strain almost wholly obliterating the black. The speaker is not informed whether the inheritance in hybridization of these apparently new characters has been tested. If a new character has been added it should maintain itself and segregate after hybridization.

The experiments conducted by Dr. Smith and others at the Illinois Experiment Station on selecting high and low strains of corn with reference to oil and protein content, have resulted in markedly distinct strains possessing these qualities, which are inherited apparently as long as the selection is continued. It seems certain that the oil and protein content has been increased considerably beyond the maximum which existed in the original race. The writer is informed by Dr. Smith that experiments have been made in cultivating these varieties without selection and that the new characters have been maintained for several years without marked regression. We must apparently conclude then that new heritable characters have been acquired in the course of the selection, but it will probably be difficult to determine whether the advance is to be considered as a cumulative effect of the selection of fluctuations or the gradual purification by the selection, of mutants which occurred during the selection or possibly even before the first selections were made. The purification of a type even when the character concerned is easily observable is known to require a number of years unless both parents are carefully followed. Whether these qualities will segregate as unit characters after hybridization has not been determined so far as the writer is informed.

Very many cases of increases obtained in quantitative characters could be cited, but the majority of the experiments were un-

dertaken primarily to obtain practical results, and whether such apparently new characters would stand the test of unit characters is doubtful.

The improvement of the sugar beet by selection forms a typical and instructive case of this kind. The careful selection of the sugar beet was started over sixty years ago by Louis Vilmorin, at which time a range of variation in sugar content of from 5 per cent. to 21 per cent. was known to exist. Since that time the industry has grown extensively until hundreds of thousands of beets are examined annually and the richest in sugar content selected for seed production. The process of selecting the beets richest in sugar content for mothers has now been continued for sixty years and is practised extensively every year, and yet there is no evidence that the maximum sugar content has been increased, and it is certain that the character of richness in sugar content has not been rendered permanently heritable, as sugar beet growers well know that their success depends upon the continuance of the selection. Here it is certain that no distinct unit character has been added by the continuous selection.

The strongest evidence as to the method of origin of new characters is derived naturally from our knowledge of known cases of the origin of such typical new characters. When we view the evidence critically, I think it must be admitted that in practically all, if not all, of the cases of new characters appearing, they have come into existence suddenly. The cut-leaved *Celedonium*, the cupid sweet pea, *Bursa heegeri*, the Otter sheep, the muley cow, are illustrations familiar to all and doubtless each of us could add several such illustrations from our own knowledge. Such new characters appearing suddenly are heritable and maintain themselves as unit

characters in hybridization. We can not but admit that the evidence of these known cases counts against the origin of characters by gradual cumulative selection.

In summarizing this part of our discussion, we can only state that at present it appears that far the greatest weight of evidence is opposed to the origin of a new unit character through the cumulative action of selection.

Are we, then, to conclude that the practice of breeders in continually selecting from the best for propagation is useless, and must we advise practical breeders to discontinue their selection? How can we do this in the light of the success of the sugar beet breeders? Have not Sea Island cotton growers increased and maintained the length and fineness of their staple by continuous selection? Have not corn growers maintained high productiveness of different strains by selection? Are not the Jersey and the Holstein maintained at a high degree of efficiency by selection? Has not the speed of our trotting and pacing horses been increased and maintained at a high rate by the most careful selection? To one familiar with the history of agriculture and breeding these questions arise fast and are likely to be insistent. There can be no doubt that the practical breeders have made advances by selecting from the best individuals. No genetist or scientific breeder will deny this. It is simply the question of the interpretation of how the results were obtained that is in doubt and whether these results can be considered as permanent, new unit characters. Before we can thoroughly understand this subject it is probable that each individual case will require to be carefully analyzed, to determine the nature of the advance made and the interpretation of the process or processes concerned. At present we can only

partially understand the phenomena presented.

It appears to me that we are dealing in breeding with two markedly distinct types of selection, based on different principles and arriving at different results, both right in principle and productive of equally valuable practical results, but of very different value, when considered from a strictly evolutionary standpoint.

It would seem that such cases of improvement as are illustrated by the sugar beet indicate that the continuous selection, generation after generation, of maximum fluctuations shown by a character, will result in maintaining a strain at nearly the maximum of efficiency; and that within a pure race the progeny of a maximum variate which would probably be classed as a fluctuation, does not regress entirely to the mean of the race in the first generation succeeding the selection, but that we only have a certain percentage of regression similar to the regression determined by Galton. It would further seem to be indicated by the evidence now available that in some cases we may even expect the continuously selected strain to exceed the ordinary maximum of the unselected population. In the Illinois corn experiments the maximum oil and protein content seems clearly to have exceeded the ordinary maximum, and is certainly maintained at a very high degree with a new mode and range of variation. If a new mutant of high protein content has been secured in the course of the experiments with a change of type it is probable that this high protein content will behave as a unit character in inheritance. Upon the other hand, if the results are interpreted as simply the maintenance by isolation of a strain produced by selecting fluctuations, there would probably be a rapid return to

the normal range of variation of this character if the selection was discontinued.

De Vries has pointed out that natural selection can produce races and maintain them, but its power to develop races beyond the natural range of variability remains to be demonstrated.

With reference to his experiments with the potato beetle Tower states:

It is demonstrated that among the fluctuating variations there are individuals which are able to transmit their particular variation and give rise by selection to a race, while the majority are not able to hand on their particular conditions to their progeny. Races developed by selection from such variations have not been carried beyond the normal limit of variability of the species.

These races or selected strains maintain themselves as long as the selection is continued, and when the selection is discontinued rapidly regress to the mean of the species.

The above examples from the sugar beet, corn and potato beetle will illustrate the type of improvement usually secured by practical breeders. By their selection they maintain a strain of high efficiency without having in general exceeded the limits of variation of the species or race and without having produced new unit characters which would be maintained without selection and segregate as pure units following hybridization.

Our different breeds of dairy animals are maintained in a state of high productivity by continuous selection. Cows are followed carefully with reference to their milk-producing capacity and their ability to transmit this quality to their offspring. The ability of bulls to beget high milk-producing daughters is taken as a test of their value. There can be no doubt, the speaker believes, that this selection within the breed maintains the breed in a state of high efficiency and is absolutely necessary

to the success of dairying. Strictly speaking, in the course of this selection, however, no new type has been produced. It is well recognized that the continuous selection is necessary to the maintenance of high milk-producing capacity, and if the selection were discontinued the average milk production of any dairy herd would rapidly decline until it reached the normal mean for the breed concerned. The same can not be said, however, of the breed or race characters, that is, those characters which distinguish the breeds or races from other breeds. Selection is not necessary to maintain the general characters of the Holstein breed for, as long as it is not crossed with other breeds, it will in general maintain its characters so far as color, conformation, and dairy type are concerned. The same may be said of any of our breeds of cattle and horses. The high efficiency of our race horses is maintained by the most careful selection and yet probably in most cases no distinctly new character is added, which would maintain itself as a unit character in inheritance.

It is true that we are dealing here with complex phenomena and limited exact experimentation, and a distinct mutant in the direction of high efficiency might occur at any time and be chosen for breeding which would maintain itself without continuous selection.

It is interesting at this point to recall one of the most common differences between plant and animal breeding which is seldom clearly recognized by practical breeders. Plant breeders most commonly strive to produce new races or breeds with distinctive characters which will reproduce their desirable qualities without continuous selection; while animal breeders almost wholly limit their attention to selection within the breeds already established, to maintain them in the highest state of effi-

ciency possible. The failure to understand this difference in purpose has frequently led to confusion in our discussions.

It is beyond the scope of this paper to discuss the kinds of variation used in these different types of selection, even if we possessed the requisite knowledge, which is doubtful. The speaker may be pardoned, however, for digressing far enough to state that it is his conviction that there is no very hard and fast line between that variation which is in considerable degree inherited, such as is found frequently in high milk-producing cows in selection within the breed, and the mutation which gives absolute inheritance and establishes a permanent new mode. The great difficulty in determining whether there is any true cumulative action of selection which will extend a character beyond the limits of the race or species is met in determining what are and what are not mutations. My experience has led me to conclude that the continuous selection of maximum fluctuations in a certain direction may in some cases lead to the gradual strengthening of the character until finally it may become, more or less suddenly, fully heritable and it would then be recognized as a mutation.

In many cases we find exceedingly small differences maintaining themselves generation after generation under different environments when the lines of descent are kept pure. A marked illustration of this is afforded by Mr. Evans's studies on pure lines of *Stellaria* reported at this meeting. The segregation of such characters in hybridization would be exceedingly difficult to recognize if it did occur. Again the occurrence of such small mutants, if we may so designate them, within a breed under selection, if not recognized and isolated, would be crossed with fluctuations and cause variations which would be recog-

nized as regressions in the highly selected strain.

I think it will have become clear from the above discussion that in the present state of our knowledge of selection we can only advocate that practical breeders continue their selections as in the past. This is particularly true in the cases where it is the idea to maintain the race or breed at its highest efficiency. In the case of plant breeders working to produce new races, the mutation theory introduces a new element and leads the breeder to search for a mutant possessing desirable characters which he can isolate and which he may expect will reproduce its characters as soon as he has purified the type from mixtures derived through hybridization with other types. He will select the type to purify it rather than to augment its good qualities.

Returning again to the question of new characters, we may profitably question more definitely where such new characters come from, if they are not produced by selection. Clearly, no problem is of more importance to the breeder than to be able to definitely produce or cause such new characters to appear. If the breeder must await the pleasure of nature to secure the changes he desires, the waiting may be long and tedious. If he must watch thousands of plants of a certain race or species every year in order to find the apparently accidental variation or mutation in the direction of the improvement he has in mind which may rarely or never be found, the process will be so hazardous that we should have to await the accidental discovery of any new characters. Indeed, up to the present time we have had practically no other recourse than to await the accidental discovery of such new characters. We, however, have had many theorists and investigators who believed that changed environment would stimulate the production

of variations in the direction of better fitting the organism to its environment. Lamarck and his followers have strongly maintained this hypothesis and many scientists even to-day believe in the effectiveness of environment in developing adaptive changes. Breeders have carried this principle so far as frequently to advocate the growing of plants in the environment most likely to produce the change desired, as, for instance, cultivating tall plants like twining beans in the north or at high altitudes if it is desired to produce a dwarf type or, *vice versa*, breeding the plants in the south and at a low altitude if a giant or tall type is desired. Weismann and his school of followers have apparently exploded this idea by demonstrating that characters acquired as a result of changed environment are merely physiological changes and are not inherited. The question, however, is by no means settled and we must await further evidence.

Knight believed that increased food supply caused an increase in the range of variation and that it was important for breeders to manure their plants heavily. De Vries, on the contrary, would have us believe that such variations are fluctuations and non-heritable. The studies of Weisse, Reinhold, MacLeod, Tammes and Love have given us many instances where the range of variation is increased as a result of food supply and other instances where the variation is apparently greater on poor or sterile soil.

It would seem that any treatment that would increase the range of variation, in plants that are grown for breeding purposes would be valuable, but it still remains to be definitely proved whether such increases in the range of variation are in any marked degree heritable and whether valuable maximum variates can be more frequently produced in this way than would

be found in similar groups of plants under ordinary treatment.

It is only very recently that the idea has developed that we can go farther than possibly change the environment. With the publication of MacDougal's researches in 1906 describing mutations that were apparently caused by injecting the capsules of plants with certain solutions, such as zinc sulphate, magnesium chloride and the like, a possible new method of forcing variations was introduced. MacDougal apparently obtained marked variations as a result of his treatment, which were inherited in succeeding generations.

Tower, by subjecting potato beetles during the formation of the germ cells to extremely hot and dry or hot and humid conditions with changes of atmospheric pressure, was able to cause the development of marked changes or mutations which were found to transmit their characters true through several generations and which segregated as unit characters following hybridization. He concludes from his experiments "that heritable variations are produced as the direct response to external stimuli."

Gager has produced similar changes in plants by subjecting the developing ovaries of plants to the action of radium rays and a number of similar studies by Hertwig and others indicate that radium emanations have a very active effect on both plants and animals.

While the evidence favoring the value of such external stimuli as the above in producing new heritable characters is apparently definite and positive, the extent to which the method can be used in practical breeding has not been determined, and indeed we must await further evidence before we can finally accept the evidence, or the interpretation of the evidence, presented in these very valuable and suggest-

ive researches. Dr. Humbert carried out experiments in the speaker's laboratory in which the capsules of a pure line of a wild plant *Silene noctiflora* were injected with the solutions used by Dr. MacDougal, and although the number of plants handled (about 15,000) was apparently as great or greater than was used in MacDougal's experiments, no mutations were found in the treated plants which were not also found in the untreated or check plants.

Some observations and experiments are recorded in literature which indicate that mutilations or severe injury may induce the development of mutations. Most noteworthy among such observations are those of Blaringham, who by mutilating corn plants in various ways, such as splitting or twisting the stalks, apparently produced variations which bred true without regression and which he described as mutations. My own observations on the great frequency of striking bud variations on recovering trunks of old citrus trees in Florida, following the severe freeze of 1894-5, also furnished evidence in support of this theory.

In general, it is assumed that in hybridization we are dealing merely with characters already present and that new characters which appear are due to the different reactions caused by new associations of unit characters in their mutual effect on one another. It is, however, possible that new unit characters may result from the commingling of the different hereditary units which are to be considered as mutations rather than new combinations. As is well known, Weismann long ago advanced the hypothesis that valuable variations in evolution were due to the commingling of protoplasts from different parents having different hereditary tendencies, a process which he called "amphimixis." He did not have in view, however, the formation

of new unit characters as distinct from new combinations.

The most marked case known to the speaker, of the appearance of a new character which was apparently caused by the stimulation of hybridization, is the development of a marked spur or horn on the lip of a hybrid *Calceolaria*. This occurred among a series of hybrids between a herbaceous and a shrubby species made by Professor Atkinson and Mr. Shore, of the botanical department at Cornell University. One or two tapering horns about an inch in length and from 2 to 4 millimeters in diameter at the base, spring from the upper surface of the large corolla lip and grow erect to its surface. No such character, so far as can be learned, is known in the *Calceolarias* and it would seem to have been caused by the hybridization. It can not, apparently, be considered as a combination of any of the known characters of the species concerned.

Such apparently new characters appear rather commonly among large batches of hybrids, and while there is little evidence available on the subject, I am inclined to believe it will be found that hybridization may stimulate the production of new unit characters, which mendelize with the parental types.

While the evidence at our command regarding the artificial production of mutations is not yet sufficiently exact and trustworthy to enable us to draw definite conclusions and formulate recommendations for practical breeders, it may be stated that this is apparently one of the most profitable lines of experimentation for the immediate future.

Thus far I have only incidentally discussed hybridization and the advance of our knowledge in this direction. The scope of this address will not allow of an adequate treatment of this subject and it ap-

peared wiser to discuss more in detail the problems of selection and variation. I can not, however, close this address without referring to this very important field of genetics.

No discovery in the field of breeding has had more effect or is more far reaching in its importance than the discovery of what have now come to be known as Mendel's principles of heredity. While, as stated in the beginning of this address, breeders had long before the rediscovery of Mendel's papers come to understand that there was a segregation of characters in the F_2 generation and that it was possible to recombine in certain hybrids the desired characters from different parents, there was no definite understanding of the underlying principles, and no conception of the almost infinite possibilities of improvement which the field of hybridization opened to us.

The law of dominance, while not universal, has explained many cases of prepotency in one generation and failure of certain individuals to transmit the character in the next generation. It has explained many cases of latency of characters and may account for all such cases.

The law of segregation has shown us that the splitting of characters follows a definite method and that we can in general estimate the frequency of occurrence of a certain desired combination, if we know the characters concerned to be simple unit characters.

The study of hybrids has been resolved into a study of unit characters and their relation to each other. By hybridizing related types having opposed characters and observing the segregations which occur in the later generations, we analyze the characters of each type and determine when we have a character pair. The researches on this subject by Mendel, Bateson, Davenport, Castle, Punnett, Shull, Hurst, Cor-

rens, Tschermak, East and dozens of other now well-known investigations, have developed a science of heredity of which we had no conception a few years ago.

We can now study the characters presented by the different varieties of a plant or of different species, which can be crossed with it and definitely plan the combination of characters desired in an ideal type, and can with considerable confidence estimate the number of plants it will be necessary to grow to get this combination. We now know in general how characters behave in segregation and inheritance so that we can go about the fixation of a desired type, when one is secured, in an orderly and intelligent way.

The farther the study of characters is carried the more we are coming to realize that the appearance of apparently new types following hybridization is due to recombinations of different units which in their reactions give apparently new characters. As an illustration, in a study of pepper hybrids which I have carried on during the past four years it has become evident that the form of plant and branching is due to three pairs of characters or allelomorphs; namely, first, erect or horizontal branches; second, large or small branches; and third, many or few branches. In crossing two medium-sized races, one with large, horizontal and few branches, and the other with small, erect and numerous branches, there result many new combinations of characters, among which appear some with small, horizontal and few branches, which gives a dwarf plant, and others will have a combination of large, erect and numerous branches, which gives a giant plant. These dwarfs on the one hand and giants on the other, appear as distinct, new creations, though they are very evidently merely the recombinations of already existing unit characters, and dwarf-

ness and giantness are the results of the reaction of the different units combined.

When we remember the large number of distinct characters which are presented by the very numerous varieties of any of our cultivated plants, we arrive at an understanding of the possibilities of improvement which the field of hybridization affords, yet I doubt if many of us have even then an adequate conception of the possibilities. Possibly I may make this more clear by an illustration from my timothy breeding experiments. While the various characters presented by the different types under observation have not been carefully studied in inheritance, the following characters can be distinguished plainly, and from observations on accidental hybrids are known to segregate. The following is a list of 28 such character pairs which it is believed will prove to be allelomorphs.

TIMOTHY CHARACTER PAIRS

Heads

Long or short.
Thick or thin.
Dense or lax.
Greenish or purple when young.
Gray or tawny when ripe.
Simple or branched.
Erect or nodding.
Continuous or interrupted.
Apex blunt or pointed.
Base blunt or attenuated.
Seeds large or small.

Leaves

Long or short.
Broad or narrow.
Erect or reversed.
Rolled or flat.
Clustered at base or extending to top of culm.

Culms

Tall or short.
Thick or thin.
Straight or wavy.
Erect or bent outward.
Green or purplish.
Many or few.

Nodes

Many or few.
Green or brown.
Internodes long or short.

Habit Characters

Lodging or non-lodging.
Rusty or rust resistant.
Early or late season.

It is possible that some of these characters may be expressions of the same unit, but in a number of cases they certainly represent several different unit characters. For instance in length of head, height of culm, number of culms, and season of maturing, several different degrees are certainly present which are fully heritable. Doubtless there are many more than 28 pairs of unit characters which could be distinguished by careful study. If we have two pairs of characters, such as tall or short and early or late, we know that 4 homozygous combinations are possible. If three pairs are considered, 8 combinations are possible. Every time we add a different character pair we double the number of different combinations that are possible. Twenty-eight character pairs would thus give us as many possible combinations as 2 raised to the 28th power, or the astonishing number of 268,435,456. It would be possible then to produce this tremendous number of different varieties of timothy if there was any reason to do so, and each variety would be distinguished from any other variety by one distinct character and would reproduce true to seed.

The task of the breeder, then, is to find which among these character combinations gives the superior plant for commercial cultivation. He will soon eliminate certain characters as unimportant and concentrate his attention on those qualities that are essential.

It would be interesting to discuss the factor hypothesis, purity of germ cell, sex-

limited inheritance and other important problems connected with inheritance studies, but I have already too severely tested your endurance.

As breeders and genetists we have every reason to congratulate ourselves on the rapid advance of our science and the growing recognition of the importance of the subject in practical agriculture. Colleges throughout the country are extending their courses of study to include genetics. In almost all of the experiment stations studies on genetics and practical breeding are now given fully as much attention as any other subject. With all of this advance, however, only in a few institutions have there been established special professorships or investigatorships in breeding or genetics. If the subject of genetics is to be properly taught or the investigations are to reach the highest standard, it is clear that men should have this as their special and recognized field. The subject should no longer be assigned indiscriminately to the horticulturist, agronomist, animal husbandmen or dairymen. We must establish more professorships of genetics or breeding.

HERBERT J. WEBBER

CORNELL UNIVERSITY

*GENERAL HYGIENE AS A REQUIRED
COLLEGE COURSE*¹

DURING the last two or three decades, scientific method has been increasingly applied to the solution of problems bearing upon the health of the individual and of the community. Out of the region of controversy, in the study of problems of the maintenance and preservation of health, there has thus come to maturity during comparatively recent years a body of organized knowledge, of which the cardinal facts and broader methods may, perhaps,

¹ The substance of an address given at Oberlin College, December 1, 1911.

be grouped together under the title "general hygiene." The more technical and detailed side of the same subject is already taught as a professional course in some of our medical schools as "hygiene" or, with nominally a more specialized bearing, as "public health." On the other hand, a somewhat slight and semi-popular treatment of several hygienic topics is given in certain colleges by the instructors in physical training. Between these two types of instruction, a course in general hygiene, very substantial although non-technical, would strike a happy mean.

Before answering the question whether the teaching of general hygiene, thus defined, to every college undergraduate is necessary, it may first be enquired whether the average student is not already well-informed on this subject. On investigation, it will be found that he may have, in an informal way, attended one or two popular health lectures; that he has a hear-say, gossiping knowledge of the names of the commoner diseases, with a more personal but badly proportioned knowledge of one or two; has never seen a microbe, although he can use the word correctly; trusts implicitly to the initiative of the local civic authorities (who are less well educated than himself) for improvement in his supplies of water, milk and food; and is indebted to his newspaper or magazine for a variety of scraps of knowledge in the domain of preventive medicine, which scraps, if not partially forgotten, are admixed with much that is vague, or controversial or else fallacious. The fact is that his knowledge of general hygiene is altogether accidental and amateurish in character. Now, if the average undergraduate is in a twilight of ignorance in regard to aspects of this subject where knowledge would be vitally important to himself, he is in still greater darkness in

regard to those aspects which are of importance to the community. In this respect, therefore, he is altogether unqualified for good citizenship.

It is true that the larger cities have, in general, progressive health departments. The chief difficulty which these departments have to contend with in their efforts at reform is the ignorance of the public. Their battle is the old battle against ignorance. If only the people had a clear knowledge of the facts, they would themselves clamor for the very reforms that the health departments can not yet introduce simply because public opinion is not yet sufficiently educated. In the smaller cities and towns, many municipal conditions are excellent because their utility is obvious and because, being of a purely economic character, they are understood by business men. This is not at all the case with the hygiene of such towns, for the good reason that people and civic authorities alike do not, for want of the appropriate education, realize what conditions are desirable for the public health. Milk inspection and food inspection are not rated at their true value for want of the necessary mental perspective. The town sells water whose purity is not controlled. Appropriations made for the health department are entirely inadequate and the health officer, therefore, lacks the sinews of war against disease. This state of matters is typical of the smaller cities and towns of this country. The remedy lies in an educated public opinion; and who, in such a community, should be the leaders and educators of public opinion rather than the college graduates?

It is not at all necessary, in the meantime, to make any rigid decision what should constitute the essentials of a course of general hygiene, nor to determine how the emphasis shall be distributed between

personal hygiene and public hygiene. The precise content of the course can be outlined after it is decided that something of the kind must be taught. Now, if there is any reason for teaching civics in college, there is at once a still better reason for teaching public hygiene. Again, if you make "physical culture" a required course and compel each undergraduate to take exercise, are you not in a position to join to this an exhortation that he shall sterilize his toothbrush? It is absurd that any post-Levitician scheme of physical education should rely upon exercise alone for health.

To a people living amid artificial surroundings, the kind of special knowledge that promotes physical efficiency may not be the most important of all knowledge, but it is at least a very necessary kind of knowledge. Upon this matter, Herbert Spencer's judgment is still modern. We are probably tired of the threadbare subject of ventilation, and bored at the mention of the low humidity of steam-heated buildings. But do many of us yet ventilate adequately, or suitably moisten our living air? Do we have in mind the direct relationship between ventilation and bad-air diseases in terms of facts sufficiently definite to spur us to action? Are we positive and militant in our knowledge of the sources of infection and the modes of transmission of communicable diseases; or, when we ought to act, do we remain supine because our knowledge is not a compelling knowledge? Can our typical undergraduate pass a simple examination even on such well-canvassed subjects as diphtheria antitoxin, deep cuts and tetanus, mosquitoes and malaria, pasteurization of milk, sunlight and germs, spitting, dust, flies and the dozen other familiar newspaper topics; or is his knowledge even of these topics too entirely in journalese?

It should be recalled that the war with ignorance is nowadays not only with ignorance of the ways of nature, but also with ignorance of the deceits and methods of wickedness of our fellowmen. As part of their equipment for the battle of life is it, then, anything more than common fairness to give to our college youth at least the bare facts in regard to typical "cough cures" (containing morphine, codeine, heroine, cannabis indica, chloroform, ether), "catarrh powders" (containing cocaine, etc.), asthma, headache, colic, tobacco and drug habit cures (the last themselves containing morphine) and medicated "soft-drinks" (containing caffeine, extract of kola nut, etc.)? "It may be of interest to note that life insurance companies are considering the status of soft-drink habitués as future risks."² When the particular drug alcohol is under discussion, we are reminded of the strongly partisan, unbalanced and therefore unconvincing oratory of a certain type of temperance lecturer. Upon this and several other subjects it were surely wiser to give the undergraduate the benefit of a scientific and dispassionate statement of the facts, removed from all suspicion of the distortions arising from controversy. The facts require no garnishing.

It is a platitude that the fraudulent, worthless or harmful drugs, "remedies" and "treatments" are introduced to and used by a very wide public because of their very wide advertising in the newspapers. There are, indeed, a few newspapers which will not print such advertisements, but these are honorable exceptions to a general rule. The government and medical association laboratories, whose analyses expose the nature of these drugs, do not similarly advertise their exposures in the public

press, nor do they by their own publications reach a wide public. Under these circumstances has not the college, as a public institution, a duty to fulfil in spreading the truth? For all our colleges must be regarded as public institutions—state-aided colleges and universities most obviously of all. Stating the case generally, therefore, can we not fairly say that the colleges, in their relation to the state, are in duty bound, in partial return for public moneys expended upon them, to contribute, by educating their students in hygiene, towards that most important factor of the public welfare, the public health?

Turn now to the question whether instruction in general hygiene as a required course could be sound educationally without the postulation of half a dozen prerequisite courses that could not be made required courses. The *a priori* answer to this question must be left to the experts. In our opinion, however, there are no difficulties here that are insurmountable. It may be recalled, in the first place, that, in some states, the public schools, with their "physiology" teaching, have already begun a type of instruction which it would be perfectly good pedagogy to continue in college. That the school should be more progressive than the college seems, by the way, to be the normal condition of affairs. The general hygiene course need not necessarily be made a freshman course; thus, many students may come to this course with some previous training in contributing sciences. Taking, therefore, what would appear to be the most unfavorable case, that, namely, of the student who has touched no science whatever, let us consider to what pedagogical catastrophe he will be subjected in studying general hygiene. It has been said above that the rapid modern growth of this science is

²Dr. Kebler, chief of the Division of Drugs, Bureau of Chemistry, U. S. Dept. of Agriculture.

attributable, in general terms, to the increasing application of scientific method to health problems. It may now be added that many of the very most striking examples of successful application of scientific method are to be found precisely in this domain. Here, therefore, is to be found one of the richest fields in which to exemplify and illustrate scientific method. To a student entirely innocent of science such a course would, in this way, be of superlative value as an introduction to scientific method, and this apart altogether from any utilitarian value inherent in the facts presented. Laboratory work, although we often make a fetish of it, is by no means a *sine qua non* in the teaching of scientific method; and the teaching of a substantial though non-technical course in hygiene would, from the very variety of the contributing sciences, offer exceptional opportunities for utilizing the whole battery of modern methods of class-room demonstration.

Some one has truly said that, as a nation, we are prodigal of nothing in so great a degree as of our health. It is the chief of the wastes of our national resources, our largest preventable waste. To be effective, a knowledge of preventive medicine must be in the hands of the many, whereas a knowledge of merely remedial medicine may be effective in the hands of the few. To conserve our health resources, therefore, the logical policy is plainly to teach prevention to many and cure to a few. To the medical student, who is a specialist, teach cure; but to the general student teach prevention. If prevention can not be taught more widely still in the community, its teaching in colleges makes it at least possible that, in this matter, the college graduates may become the little leaven that shall leaven the whole lump.

If it be true that the last few decades

have witnessed abnormally swift progress in the science of preventive medicine, and if it also be true that the development of a social conscience has been unusually rapid in recent years, then it may well be the case that the time for requiring the teaching of general hygiene in our colleges is now at hand.

ALAN W. C. MENZIES

THE UNIVERSITY OF CHICAGO

ELIZABETH THOMPSON SCIENCE FUND

THE thirty-seventh meeting of the board of trustees was held on February 9 last at Cambridge, Mass. The records of the last meeting were read and approved. The following officers were elected:

President—Edward C. Pickering.

Treasurer—Charles S. Rackemann.

Secretary—Charles S. Minot.

The secretary reported that a pamphlet, giving the record of the Fund for the twenty-five years of its existence, had been prepared and printed in accordance with the vote of last year. This carries the record of the fund to April, 1911. In compiling the matter for this record valuable assistance had been received from Dr. F. T. Lewis. Copies of the report have been sent to each of the trustees, to all living recipients of previous grants, and to a small number of libraries and institutions. Any one desiring a copy of the report should address the secretary.

The secretary reported that additional publications had been received connected with grants, the record of which had been closed, as follows:

139. Joh. Königsberger.

153. W. Doberck.

159. B. M. Davis.

It was voted to close the record of grants 117, E. Salkowski, and 146, M. Nussbaum. No reports had been received from the holders of grants Nos. 22 and 27, 109, 112, 124 and 147. The trustees much regret that the recipients of these grants have failed to ful-

fill the obligations they have assumed. Reports were received from twenty-seven holders of grants and accepted as reports of progress. It was voted to make the following new grants:

No. 170, \$100 to Professor Arthur L. Foley, Indiana University, Bloomington, Indiana, for photographic researches on the spectra of various gases, the money to be applied to the purchase of quartz tubes. (Application 1,243.)

No. 171, \$250 to Professor Paul Schiefferdecker, Bonn, Germany, for the investigation of the microscopic structure of muscles. (Application 1,252.)

No. 172, \$75 to K. Stolyhwo, rue Kaliksta, Varsovie, Poland, for the archeological exploration of the Cave of Lary, Poland. (Application 1,264.)

No. 173, \$180 to Professor H. Konen, Fürstenergerstrasse 4, Münster, W., Germany, for the study of the lower end of the spectrum, the money to be used for the purchase of quartz rock salt objectives. (Application 1,245.)

No. 174, \$100 to Dr. Paul D. Lamson, Bahnhofstrasse 20, Würzburg, Germany, for researches on the pharmacotherapy of snake-bites. (Application 1,258.)

No. 175, \$40 to W. Dobereck, Esq., Kowloon, Elgin Road, Sutton, Surrey, England, for observations on comets, the money to be used for the purchase of a comet eyepiece. (For application, see Grants made, Report 383.)

No. 176, \$250 to Professor Th. Boveri, Zoologisches Institut, Würzburg, Germany, for experiments on the rôle of the separate elements of cells in heredity. (Application 1,249.)

CHARLES S. MINOT,
Secretary

HARVARD MEDICAL SCHOOL,
BOSTON

JOHN BEERNHARDT SMITH

THE many personal friends of Doctor John Bernhardt Smith, state entomologist of New Jersey, had known for many months that he was in a most serious condition of health, but were none the less shocked and grieved to learn of his death on March 12 last.

Few men have contributed more to the advancement of the study of entomology in the United States, through both the systematic

and economic sides, than has the late New Jersey entomologist. He was born in New York City on November 21, 1858, and was educated in the schools of New York City and Brooklyn. He was admitted to the bar in 1880 and practised law in Brooklyn between 1880 and 1884. As a young man, he was greatly interested in the study of insects and joined the Brooklyn Entomological Society, devoting himself at first to the study of Coleoptera and afterwards turning his attention to Lepidoptera. He became the editor of the *Bulletin* of the Brooklyn Entomological Society which afterwards developed into the journal known as *Entomologica Americana*, the most prominent periodical of its kind in those days for the publication of short papers and notes.

Up to 1884, Doctor Smith was known only as a systematic entomologist, but in that year he was brought by the late C. V. Riley to Washington and became field agent of the Bureau of Entomology, U. S. Department of Agriculture, and spent two years in investigating insects affecting the hop and the cranberry. In 1886, he was transferred to the U. S. National Museum, where he remained as assistant curator of insects until 1890.

During this period, he was active in his systematic work publishing a number of excellent papers, and became prominent in the scientific life of Washington, joining the Cosmos Club and being made secretary of the Biological Society of Washington.

With the founding of the state agricultural stations under the Hatch Act, he was appointed entomologist of the State Agricultural Experiment Station of New Jersey and there really began his important economic work, which lasted until his fatal illness came. All the difficulties of insect emergency which the agricultural and horticultural interests of New Jersey had to face during that period were met by Doctor Smith with a rare comprehension and an equally rare ability to handle them. He was foremost in the work against the San Jose scale in the early days and took an equal rank in the warfare against all the other threatening foes to agriculture and, in the last few years, conducted an admirably

planned and successful crusade against the traditional insect of New Jersey, the mosquito. His mosquito work was based upon original observations which introduced revolutionary ideas into culicidology and his work on the salt marsh mosquitoes which fly inland from their breeding-places for many miles came as a startling revelation to the "old foggy" students of mosquitoes, of whom the writer of this notice was one. Further than that, Doctor Smith so impressed his views upon the legislature and the governor of his state that his mosquito work was supported by large appropriations.

Through all this period of economic work, Smith was constantly working upon other aspects of entomology. Every few months would appear a systematic paper upon that difficult and complex group, the family Noctuidæ, and in the course of his New Jersey career he published two enormous catalogues of the insects of New Jersey.

He was also the author of two admirable books, "Economic Entomology for the Farmer and Fruit Grower," Lippincott, 1896, and "Our Insect Friends and Foes," Lippincott, 1909. In addition to the position of entomologist of the New Jersey State Agricultural Experiment Station, he was professor of entomology in Rutgers College and state entomologist of New Jersey. He was president of the Association of Economic Entomologists in 1896 and president of the Entomological Society of America in 1910. In 1891 he was given the honorary degree of Sc.D. by Rutgers College.

While not a pioneer in entomology in the United States, Smith was a leader in the second generation of men who have helped to make American economic entomology assume the first rank in the world. L. O. HOWARD

SCIENTIFIC NOTES AND NEWS

PROFESSOR ABBOTT LAWRENCE ROTCH has bequeathed to Harvard University the Blue Hill Meteorological Observatory, which he established in 1885 and had directed up to the time of his death. He has further provided an endowment fund of \$50,000.

THE will of Lord Lister disposes of property valued at £66,166. In addition to a number of family bequests he left £10,000 each to the Royal Society, King Edward's Hospital Fund, King's College Hospital and the North London and University College Hospital. He stated that he did not wish that his name should be "in any way associated with these sums in the future." He also left £20,000 to the Lister Institute of Preventive Medicine, and requested his nephews, Mr. Rickman John Godlee and Mr. Arthur Hugh Lister, to arrange his scientific manuscripts and sketches, destroying or disposing of such as were of no permanent scientific interest. He left his manuscripts and sketches when so arranged to the Royal College of Surgeons, England. In the bequest of his Orders and medals to the Edinburgh University, Lord Lister stated: "I expressly declare that it is my intention that the university authorities for the time being shall be perfectly at liberty to dispose of all or any part of the gift—for example, by having the medals melted down or the diplomas or other writings destroyed—at any time and in any manner that may seem to them desirable."

DR. IRA REMSEN has tendered his resignation as president of the Johns Hopkins University. He will remain professor of chemistry, which he has been since the opening of the university in 1876. Dr. Remsen's letter of resignation in part reads as follows: "For some time past it has seemed best to me that I should retire from the presidency of the university, but those whom I have consulted have urged me to postpone action until certain important things have been accomplished. This has now been done and I accordingly tender my resignation to take effect at the end of the present academic year. I have held the position for eleven years. This covers a fairly well-defined period in the history of the university, a period of steady growth and especially of preparation for a new era, which while maintaining and strengthening the old ideals and high standards of the university, will lead to larger and in some directions new

fields of activity and usefulness, if properly administered. We are face to face with new problems which will require wise consideration for many years to come. It is not to be expected that I shall be able to guide the policies which are to be inaugurated for a sufficient length of time to insure their ultimate success. I, therefore, feel that they should be intrusted to one having a reasonable expectation of long term of service.

THE Elisha Kent Kane Medal of the Geographical Society of Philadelphia has been awarded this year to Professor Wm. Morris Davis, of Harvard University.

THE Longstaff Medal of the Chemical Society, London, has been presented to Dr. H. Brereton Baker, F.R.S.

THE Turin Academy of Sciences has awarded the Vallauri prize of £800 for contributions to the progress of physics in the period of 1907-1910 to Professor A. Righi and Professor J. Perrin.

THE Royal Geographical Society has made its awards as follows: The Victoria medal to Sir George Darwin, of Cambridge University; the founders medal to Mr. Charles Montague Doughty, known for his explorations of Arabia; the patrons medal to Mr. W. Caruthers, who has conducted expeditions in Turkestan and Arabia; the Murchison bequest to Captain W. C. Macfie, R.E., for his topographical survey of Uganda; the Gill memorial to Captain F. M. Bailey, who has made explorations in China and Thibet. The Cuthbert Peek fund to Mr. Cecil Clementi, who has traveled extensively in central Asia; the Black bequest to Mr. L. A. Wallace, who has made surveys in Rhodesia.

PROFESSOR E. METCHNIKOFF, assistant director of the Pasteur Institute at Paris, has been elected foreign associate of the French Academy of Sciences, in succession to Sir Joseph Hooker.

SIR DAVID GILL, K.C.B., F.R.S., has succeeded Lord Cromer as president of the Research Defence Society; Lord Cromer, Mr. Balfour, Sir Edward Elgar, O.M., Mr. Rud-

yard Kipling and Lord Rayleigh, O.M., have consented to be vice-presidents of the society.

MR. C. E. ADAMS has been appointed government astronomer for the dominion of New Zealand.

MR. HARLAN I. SMITH has been elected honorary curator of archeology in the American Museum of Natural History.

PROFESSOR J. C. ARTHUR and Dr. Frank D. Kern, of Purdue University, are spending a few days with Professor F. E. Lloyd, at the Alabama Polytechnic Institute, making it the center of field operations in the study of the *Uredinæ*, with the especial purpose of identifying the at present unknown alternate hosts of certain species.

DR. W. H. WELCH, of the Johns Hopkins University, delivered the convocation address before the students of the University of Wisconsin on April 12.

At a meeting of the Southern California Academy of Science on April 6, Dr. David Starr Jordan, president of Stanford University, gave an address on "Eugenics."

THE Norman W. Harris lectures of Northwestern University will be given by Dr. Milton J. Rosenau, professor of preventive medicine and hygiene in Harvard University. The lectures will be delivered from April 15 to 20, the general subject being "Milk and its Relation to Public Health." The successive lectures deal with "Dirty Milk," "Diseases Spread by Milk," "Clean Milk," "Pasteurization" and "From Cow to Consumer."

MRS. CHRISTINE LADD FRANKLIN has given three university lectures on color vision before the department of psychology of Columbia University, as follows:

March 25—"The Theory of Color Theories—The Color Triangle and the Color Square—The Facts inconsistent with the Hering Theory."

March 27—"The Young-Helmholtz Theory in its Latest Form—its Indispensableness and its Inadequacy."

March 29—"The Recent Views on Color—Bruner, Pauli, Bernstein, Schenck—The Development Theory of Color."

Dr. D. T. MACDOUGAL gave a lecture on the "Physical and Biological Aspects of American Deserts" to the members of the Colonial Institute, Geographical Society and Natural Science Society of Hamburg on March 23.

Dr. R. M. PEARCE, professor of research medicine at the University of Pennsylvania, will deliver at the Syracuse Medical School the annual Alpha Omega Alpha address of the Gamma of New York Chapter. The title of the address is "Medical Education." Dr. Pearce will be the guest of honor of members of the fraternity at their annual dinner at the Onondaga.

Dr. W. A. EVANS, sanitary expert of the Chicago *Tribune*, has given three lectures at the University of Illinois on health topics. Dr. Evans aided in the establishment several months ago of the Champaign County Anti-tuberculosis Health League which is now making a sanitary survey of the county and has an employed inspector, Dr. Carrie Noble White.

PROFESSOR IRVING FISHER, of Yale University, lectured before the undergraduates at Oberlin College on April 4 on "Some Aspects of the Modern Public Health Movement." Dr. Fisher explained the significance of the International Health Exposition at Dresden, and devoted a large part of his address to emphasizing the value of eugenics. He called particular attention to the scientific methods employed in Germany and in Sweden to guard against the spread of tuberculosis and typhoid fever, and gave a brief analysis of the statistical treatment of the health problem in the United States, urging the great need for more thorough registration of births, deaths and the general care of vital statistics by scientific methods.

THE Academy of Natural Sciences of Philadelphia, at its meeting of April 2, adopted the following minute:

The Academy of Natural Sciences of Philadelphia has heard with deep regret of the death of Professor Thomas Harrison Montgomery, Jr., on March 19, 1912. Professor Montgomery was a grandson of Samuel George Morton, president of this academy from 1849 to 1851, widely known for

his collection and study of human craniology. To that ancestor we may trace Montgomery's taste for natural history which led him to study zoology in the University of Berlin (where he received the Ph.D. in 1894) and to fill positions of instruction and research in the Wagner Institute, the Wistar Institute, the Woods Hole Marine Biological Laboratory and the Universities of Texas and of Pennsylvania. He was elected a member of the academy February 23, 1897. He served on the Committee on Instruction and Lectures in 1903 and on the Committee on Accounts from 1909. He was the first to respond to the invitation to contribute to the Centenary Memorial Volume and his memoir on Human Spermatogenesis was the last paper which he completed, although he did not live to read it at the anniversary meeting. Barely more than thirty-nine years of age when he died, he would have been justified in a feeling of pride in what he had accomplished. He had made fruitful suggestions on the mechanism of inheritance, based on his studies of minute details of the structure of the germ cells; he had investigated the anatomy of the unsegmented worms, rotifers and spiders; he had made known many interesting habits of spiders and of birds; his breadth of outlook and of zoological knowledge was displayed in his book on the "Analysis of Racial Descent in Animals." From all that he had done we rightly expected much to come from his further researches and our sorrow at his departure is made keener by his fulness of promise.

MR. GUSTAV POLLAK is preparing a biography of Michael Heilprin and his sons, and will be glad to receive letters by the late Professor Angelo Heilprin. They may be sent to 21 West Eighty-fifth Street, New York.

Dr. PERRY L. HOBBS, professor of chemistry at Western Reserve University, died on April 6, aged fifty-one years.

THE death is announced of Dr. P. N. Lebedew, professor of physics at Moscow, known for his work on the pressure of light.

THE eighteenth meeting of the Association of Teachers of Mathematics in the Middle States and Maryland, was held at Syracuse University on April 6, under the presidency of Professor I. J. Schwatt, of the University of Pennsylvania.

THE eleventh annual meeting of the North Carolina Academy of Science will be held at

the University of North Carolina, Chapel Hill, on Friday and Saturday, April 26 and 27. Dr. H. V. Wilson is president and Dr. E. W. Gudger secretary.

THE Philosophical Institute of Canterbury, New Zealand, which came into existence on August 30, 1862, will celebrate its jubilee this year. It is proposed to mark the occasion by holding a gathering in Christchurch.

MESSRS. CONSTABLE AND COMPANY announce the publication, beginning in April, of a new quarterly review to be called *Bedrock*. The acting editor is Mr. H. B. Grylls, and there is an editorial committee consisting of Sir Bryam Donkin, Professor E. B. Poulton, Dr. G. Archdall Reid and Professor H. H. Turner.

THE American Museum of Natural History has secured, through the generosity of Mr. J. P. Morgan, Jr., the collections of minerals and meteorites left by the late Stratford C. H. Bailey, of Oscawana-on-Hudson. Mr. Bailey had been an indefatigable collector for many years and had assembled representatives of nearly three hundred falls and finds of meteorites, at least twenty-one of which are new to the museum's already great foyer collection.

EXTENSIVE infection of the San José scale has been discovered on trees in the southern part of Wisconsin by Professor J. G. Sanders, of the University of Wisconsin. Professor Sanders, who is also state nursery inspector, reports that steps are being taken to control the pest and prevent its spreading beyond the area affected already.

THE return of the *Terra Nova* brings from the British Antarctic Expedition news of importance, if not as exciting as that from Amundsen. Captain Scott, who was nearing the South Pole at the latest report, remains another year to complete his scientific work, which should be a valuable contribution to polar knowledge. The magnetic, meteorological and biological observations will form welcome additions to those of previous explorers. Those in geology will probably prove to be of primary value. Near Granite Harbor have been discovered marble, topaz, fossils (probably Crustacean it is said), and coal of

economic value. Two species of wingless insects were found in large numbers, and are an unexpected addition to Antarctic fauna. Scientific men will await with interest the detailed report on the fossils, with their reference to, or connection with, the Antarctic specimens from Seymour and other islands to the east of Palmer Land. It will be recalled that Larsen, in 1892 and 1893, brought from Seymour Island, petrified wood and mollusca. In 1902 Professor Otto Nordenskiöld very greatly increased knowledge along these lines. His collections from Seymour, Snow Hill and Cockburn Islands were rich in types of the Jurassic system. Among fossils discovered by him were beeches, cycads, ferns, firs, pines ammonites, etc., and of giant penguins, seven feet tall, considerably larger than the emperor penguin of to-day.

THE *Carnegie*, in command of W. J. Peters, arrived at Manila early in February and is now *en route* to Suva, Fiji Islands. From thence she will proceed to San Diego, California, instead of Acapulco, Mexico, as originally announced. Besides Mr. Peters, the present scientific personnel consists of Dr. H. M. W. Edmonds and Messrs. H. D. Frary and H. F. Johnston. Dr. N. E. Dorsey, Ph.D. (Hopkins, '97), has resigned his position as associate physicist in the United States Bureau of Standards, having been appointed research associate in the department of terrestrial magnetism of the Carnegie Institution of Washington. He will have charge of special experimental and theoretical work, in which he will be assisted by Dr. R. H. Galt. Mr. E. Kidson continues the general magnetic survey of Australia. The following have been appointed magnetic observers: D. W. Berky, for work in northwest Africa with Mr. W. H. Sligh; Donald Mackenzie and H. R. Schmitt, members of Mr. J. P. Ault's party in Peru, Bolivia, Paraguay and Uruguay; C. W. Hewlett for ocean observational work aboard the *Carnegie*, beginning at San Diego, and A. D. Power. Professor H. D. Harradon, A.B. (Bates, '06), has been appointed translator and librarian.

THE University of the Philippines and the Bureau of Science will combine this year to inaugurate a marine biological survey of the Philippines. The party to take the field will be composed of Mr. Alvin Seale, chief of the division of fisheries, Bureau of Science, Dr. Lawrence E. Griffin, associate professor of zoology, University of the Philippines, Dr. Reinhart P. Cowles, assistant professor of zoology, Mr. Lawrence D. Wharton and Mr. S. F. Light, instructors in zoology, and three Filipino assistants. The station this year will be at Puerto Galera, a small harbor on the northern coast of Mindoro, where marine life is extremely abundant and the facilities for collecting observations are unusually fine. The party will be in the field about three months.

A STATION for instruction and research in biology will be maintained by the University of Michigan, for the fourth season, as a part of its regular summer session during the eight weeks from July 2 to August 23 inclusive, 1912. The station will be located near the Bogardus Engineering Camp of the university on a tract of about 1,666 acres of land owned by the university and stretching from Douglas Lake to Burt Lake in Cheboygan County, Michigan, 17 miles south of the Straits of Mackinac. This region, diversified by hills and valleys, was formerly covered by forests of hardwoods and conifers. Small tracts of the former still remain. It contains many lakes of clear water, unsurpassed in the state for size, depth and beauty of setting. The elevation of the camp, between one and two hundred feet above Lake Michigan, insures cool nights. The staff of instructors includes Professors Jacob Reighard, Frank Smith and Henry Allen Gleason, and Drs. A. F. Shull and R. M. Harper.

THE ninth annual session of the Puget Sound Marine Station will convene at Friday Harbor, Washington, on June 24, and will continue for a period of six weeks. The plant has been considerably augmented so as to provide facilities for an increase in attendance over the session of 1911, when nearly one

hundred persons were present at the station. The courses to be offered are as follows: Algology, H. B. Humphrey, Washington State College; Systematic botany, A. R. Sweetser, University of Oregon; Elementary zoology, W. A. Redenbaugh, Seattle High Schools; General ecology, H. S. Brode, Whitman College; Embryology of invertebrates, W. J. Baumgartner, University of Kansas; Ichthyology, E. V. Smith, University of Washington; Advanced ecology, Trevor Kincaid, University of Washington; Plankton, John F. Bovard, University of Oregon. Facilities will also be offered for research work along botanical and zoological lines. The systematic survey of the local fauna which has been in progress for several seasons will be continued by further deep water exploration. The director of the station, Professor Trevor Kincaid, of the University of Washington, will be glad to give more extended information to persons planning to visit the laboratory.

UNIVERSITY AND EDUCATIONAL NEWS

THE Maryland legislature has voted the sum of \$600,000, to be followed by an annual grant of \$50,000 to establish a school of technology in connection with the Johns Hopkins University.

A GIFT of \$300,000 to Princeton University from Mr. William Cooper Proctor, of Cincinnati, for the endowment of the Charlotte Elizabeth Proctor fellowships in the graduate school is announced. Mr. Proctor, who had previously given \$500,000 to the graduate school, was elected a life member of the board of trustees to succeed Mr. Cleveland H. Dodge, of New York, who resigned last autumn.

MR. E. C. CONVERSE, of New York City, has given \$125,000 to Harvard University for the establishment of an Edmund Cogswell Converse professorship of banking in the graduate school of business administration. The university has also received \$28,000 from Mrs. J. K. Paine, for the establishment of the John Knowles Paine fellowship in music.

THE University of Chicago has established a system of retiring allowances for professors

or their widows. A fund of \$2,500,000 taken from the \$10,000,000 Rockefeller gift of 1910 has been set aside for this purpose. This pension system will grant to men who have attained the rank of assistant professor or higher, and who have reached the age of 65 and have served 15 years or more in the institution, 40 per cent. of their salary and an additional 2 per cent. for each year's service over 15. The plan also provides that at the age of 70 a man shall be retired unless the board of trustees specially continues his services. The widow of any professor entitled to the retiring allowance shall receive one half the amount due him, provided she has been his wife for ten years.

MISS ROSA MORRISON, for nearly forty years superintendent of women students of University College, London, has bequeathed \$20,000 to the college to establish scholarships in English and German.

THE thirty-eighth annual commencement of the Colorado School of Mines will be held on May 24, when fifty-two graduates will receive their degrees. The address of the day will be given by Mr. William Lawrence Saunders, of New York, president of the Ingersoll-Rand Company.

DR. E. I. WERBER, assistant in anatomy at the Johns Hopkins University, has been appointed instructor in anatomy at the University of Wisconsin.

DR. DURANT DRAKE, of the University of Illinois, has been appointed associate professor of philosophy at Wesleyan University.

DR. JAMES A. BABBITT has been promoted to professor of hygiene and physical education at Haverford College.

MR. C. M. GILLESPIE, of Yorkshire College, has been appointed to a newly established professorship of philosophy at Leeds.

DISCUSSION AND CORRESPONDENCE

A DEFENCE OF THE "NEW PHRENOLOGY"

ALTHOUGH I am not a partisan of the travelling phrenologist, I am a believer in cerebral localization or, putting it in more general

form, in the localization of functions in the central nervous system. If we must make a choice between phrenology (supposing for the moment that phrenology is equivalent to localization of function), and the conception that mental processes are something transcending cerebral organization and cellular processes, then I am a phrenologist. It is evidently in this latter sense of localization that Professor Franz¹ uses the term "new phrenology."

It is true that Marie and von Monakow have shown that certain of the more or less current conceptions of focal or insular representation of cerebral function, particularly those concerning the speech center, are no longer tenable, but neither Marie nor von Monakow has denied that certain definite fibers arise from definite circumscribed areas of cells in the cerebral cortex and run to certain definite end stations. Indeed, no point of nervous anatomy or physiology seems better established than this. And stimulation of a definite, circumscribed area of the cerebral motor cortex of any one animal always elicits a response of a definite group of muscles, and never of any other groups. This definite, circumscribed cell area constitutes the focal or insular motor representation in the cerebral motor cortex of this particular group of muscles. Such a circumscribed area, frequently marked off from surrounding cells by a boundary of non-nervous tissue, is commonly known as a motor center.

It would however be an error to suppose that this group of cells is an isolated group. It has, through afferent association neurones, connections with practically every portion of the cerebral hemisphere of the same side; through commissural neurones, with practically every portion of the opposite side, and through afferent projection neurones, it is brought into relation, directly or indirectly, with the cerebellum, spinal cord and other structures. The circumscribed area of cells thus becomes a part of an extremely complex and extensive motor system, but in such participation it

¹ SCIENCE, 1912, N. S., XXXV., p. 321.

loses nothing in definiteness of location or of function. The conception of a circumscribed motor center must be superseded by the conception of a motor system or mechanism. It is to such a mechanism that we may apply the conception of integration as developed by Sherrington. Integration is essentially a dynamic rather than a morphological process; but integration implies a certain definiteness of relationships, morphological as well as dynamic, throughout any one process. We have already stated that stimulation of the particular group of cells always evokes a response of a particular group of muscles—contraction of one set and relaxation of their antagonists. And since this phenomenon of group movement is constant from day to day or year to year in any one individual, we are justified in assuming that a certain rather constant morphological mechanism integrates certain rather constant relations in time and space to a fairly constant result. This is the essence of the modern dynamic view of localization of function.

Let us apply this conception to the solution of one of the problems which puzzle Professor Franz. He cites the experiments of dividing two motor nerves and suturing the central end of one to the peripheral end of the other, with the subsequent recovery, after a period of paralysis, of movement in the respective groups of muscles supplied. The regeneration of the nerves undoubtedly means that muscle group *A* is now innervated by fibers arising from cells in the area which previously supplied muscle group *B*. There is no necessity for postulating any further anatomical change, and no basis in fact for such a postulate, even if it were necessary, since no new nerve cells arise after birth in the forms used for the experiment. We must seek an explanation, either in the relationships of the cells and their life processes, or in the entrance of some psychic or mental factor (and hence on Professor Franz's own argument, some unknown factor so far as its localization is concerned) into the readjustment.

Fortunately, the relationships of the cells and their life processes offer us some hope of

a solution. We have already mentioned the fact that the cellular insula is in relation with practically every other portion of the same cerebral hemisphere, and we should emphasize the fact that the response of the motor cells is determined largely by these afferent impulses. In the absence of afferent impulses from the muscles to which they send fibers, the motor cells cause an uncertain and inaccurate response. The mechanism of integration, while not completely wrecked, is damaged and rendered inaccurate. In the process of regeneration of the severed nerves, the sensory (in case it was previously interrupted) as well as the motor connection of the muscle with the cortex has been restored. Impulses coming in over the old sensory route and reaching their usual motor cell destination in the cortex will now produce confusion of motor response. But the ocular path is open and the animal sees its limbs. An animal which has lost all sensation in a limb, through section of the sensory roots, becomes able to control the movements of the apæsthetic limb through its visual mechanism. When the eyes are bandaged, the motor embarrassment of the apæsthetic limb returns. (Bickel.) The ocular path affords one possible, and probable, explanation of the return of motor function in the muscle groups whose nerves were severed. But the possibilities of recovery after transposing and suturing the nerves are by no means exhausted. The afferent impulses from the muscles do not reach their motor cell destinations over one neurone, but over a series of neurones. Between the cortical termination of the afferent path and the motor cells, there are intercalated association neurones. In the early period of recovery the confusion caused by the access of afferent impulses to the wrong motor end station produces an unusual stress in that particular region, and impulses may flow over previously unused channels, thereby eventually reaching, more or less indirectly, the proper destination. The final condition of equilibrium in the system will be reached when the association path from afferent cortical ending to the proper motor cell comes to be the one most

easily followed. The experiment of transposing and suturing motor nerves is successful only when nerves whose central terminations are relatively close to each other are used for the purpose. I am inclined to regard the sensory readjustment as essentially a dynamic rather than as an anatomical change.

This is only a simple case, and the physiologist does not get very far in his experiments without encountering more serious difficulties. In the higher vertebrates the situation is further complicated by the presence of two motor systems—the phylogenetically old and the phylogenetically new, *e. g.*, the pyramidal tract, as von Monakow⁷ has pointed out on morphological grounds and as I have indicated (1909) from experimental considerations. In case of injury to any part of the newer system, the phylogenetically older system may assume, in a certain degree, the functions previously belonging to the newer system. The theory of localization of function in its relation to the phylogenetic development of the nervous system enables us to give a rational and intelligible account of many nerve processes, though the lack of experimental data leaves others unilluminated. It is but fair to state in this connection that the only physiologist of modern times who maintained a perfectly consistent attitude on cerebral localization was Goltz, who denied it in toto.

It follows, as a consequence of the postulate of integration, that the character of the activity of any particular mechanism is determined, not by any one constituent part, but that the final action is the sum of the activities of the various constituent parts. A change in the relation of the afferent impulses produces a change in the motor reaction. Indeed, we may probably say that if all the relations are the same in two successive processes, even though they may be separated in point of time, the motor reactions must necessarily be alike. This is certainly true of some reactions, and may be regarded as a restatement of Hermann's law of specific re-

sponse to stimulation, and is in line with C. O. Whitman's wider generalization that "organization shapes behavior."

The theory of integrative action may be extended to the field of the special senses. The psychologists, or certain of them, have argued that, since neither the afferent nerves of special sense nor the central cells about which they terminate are sufficiently different anatomically from other afferent nerves or central cells to explain the specific energy of the sensory nerves, this difference in sensation must depend upon consciousness. In this they have been but miserable comforters. Since no one has yet told us what consciousness is, attributing a certain function to consciousness is tantamount to saying that we know little about it. If the ultimate sensation of which we become aware is due not to a single afferent nerve and a circumscribed end station alone, but to the peculiar relationships of these structures to other parts of the nervous system as well, the aspect of the problem changes somewhat. The visual sensations, for example, may be the resultant of afferent impulses over the optic nerve acting on various central stations, some of which, as shown by the course of the association tracts, may be remote from the occipital area of the cerebral cortex. If a particular sensation is the result of the action of a definitely localized integrating mechanism, consciousness, in so far as it deals with this particular sensation, is also a result of the activity of a definite organization, morphological and functional, of the brain, and is related to a fairly definite region or regions. It is doubtful whether the psychologists are in possession of sufficient facts to show that such a hypothesis of integration is impossible or even improbable. Few physiologists will deny that our analysis of the motor system and, *a fortiori*, of the system of the special senses, is incomplete, and that we do not yet know all we need to know about them. Few will deny that the analysis is difficult, and that we may be a long time finding out. I am free to admit the possibility that the views stated here may not be the final views in the matter. I am ex-

⁷"*Aufbau und Lokalisation der Bewegungen beim Menschen*," Leipzig, 1910; "*Über Lokalisation der Hirnfunktionen*," Wiesbaden, 1910.

trremely loath to admit that the analysis of the motor and sensory systems is impossible, or that it will finally be necessary to postulate any agency which transcends matter and energy as we ordinarily know them, to complete that analysis. I would strongly insist that even our present methods of analysis have not as yet been shown incapable of yielding further information. I am not quite sure, from reading Professor Franz's paper, of his position in regard to localization of the motor system, or of certain sensory systems, but I have given this survey of them in order better to show by comparison, that similar methods may be applied to the analysis of mental processes.

For my part I find it impossible to gain a clear idea of how the brain functions as a whole in motor processes. I do believe, however, that we may gain a certain degree of clearness of ideas if we suppose that certain definite circumscribed cell areas, and no others, acting through their association tracts, may evoke a definite motor reaction, and no other motor reaction. Similarly, I find it extremely difficult to see how the brain, acting as a whole and without reference to circumscribed cerebral areas or to integration systems involving two or more such areas, may give rise to a mental process. I can picture to myself a conceivable way in which several cell groups or systems, acting together in a particular manner and without special reference to the rest of the brain, may give rise to a particular mental process or conception made up of certain definite mental elements which are related in a definite way. Other parts of the brain may subsequently be involved in succeeding mental processes, but a definite order of succession may well be followed. This is, as I take it, the only fundamental difference between Professor Franz and the advocates of cerebral localization. It appears to me that the localizationists, or phrenologists if you please, have somewhat the better of the argument, inasmuch as one very valuable method of getting at the working of a mechanism as a whole is by taking it to pieces and studying the properties and reactions of each

piece separately, and attempting to determine the relations of the pieces to one another. The validity of each view must, however, be determined by the results which it can produce when applied to the analysis of nervous functions.

To many of us, mental states mean the resultant of the various sensory impressions of the moment, modified, it may be, by stored-up impressions of past incidents—the memory of past sensory impressions. To many of us, it appears, also, that sensory impressions are closely connected, in a dynamical way, with certain definitely localized anatomical mechanisms in the central nervous system. If it be true that there exist in the central nervous system such integrative sensory mechanisms, and if it also be true that mental states are but the integration, in a definite sequence in space and time of these sensory impressions, it follows that there must also be localization of mental processes with reference to these integrative mechanisms. It may be that our views of definitely localized integrative mechanisms and their functions are unfounded, but they appear to be the simplest views which, in the light of our present knowledge, we are justified in retaining.

This is not to insist that any one shall become a new phrenologist against his will, but is meant simply as a justification for those to whom it still appears that localization of function, in the sense of its dependence upon the action of localized integrative mechanisms, "is a wholesome doctrine and very full of comfort."

DEPARTMENT OF PHYSIOLOGY,
COLUMBIA UNIVERSITY

MR. DOOLEY ON SCIENCE: BEING A PROTEST AGAINST
THE VIOLENCE OF THE GENETICIST

"SCIENCE is a great thing, Hinnessy," said Mr. Dooley. "Av coorse t' a man av yer onidjicashun th' rale progriss iv science manes but little, but to thousands iv collidge professors 'tis the brith av life. Av coorse 'tisn't much iv a livin' the pore divils git, but th' likes iv them don't nade t' spind money like you and me—they havin' no bad habits."

"But what do their families do?" asked Hennessy.

"They don't have anny," said Mr. Dooley.

"Yis, science is a great thing."

"But what is science?" said Hennessy.

"I'm serprised at yer ign'rince, Hinnissy.

'Tis 'knowledge sit in orther,' as me frind Doc Wiley says. It's like this. Take yerself, Hinnissy; ye have some knowledge iv mixin' drinks, but it kapes ye in trooble because ye don't have it sittin' in orther."

"I orther what I plase," said Hennessy.

"Don't int'rupt me argiment," said Mr. Dooley. "Yer knowledge bein'—as I may say—th' common or gardin varity iv knowledge, ye gorge yerself on twd scooners iv beer and thin ye regorge yerself on two indacintly large glasses iv whiskey, and thin I have to iscoort ye home."

"Niver! with only two glasses," interrupted Hennessy.

"As I was sayin', 'tis th' orther was wrong. That's where science stips up and puts ye right. It says, the orther is beer afther whiskey; niver whiskey afther beer."

"Do ye know anny scientists?" said Hennessy.

"Some iv th' greatest," replied Mr. Dooley. "In fact, I have jist coom from visitin' wan iv me old collidge frinds, who is a great beol-lergist. As I know that ye can't consave th' proper manin' iv th' worrud Beol-lergist, I will explain. 'Tis made up iv two worruds, the worrud 'be,' 'being,' manin' annything at all that can be, and th' worrud 'oller' or 'holler.' That is, 'tis anny wan who hollers a great deal about ivry livin' thing."

"Where does yer frind worruk?" asked Hennessy.

"Niver say that worrud iv a scientist, Hinnissy. He re-e-tains a posishun iv thrust an' responsibility with our great an' gloryus government at Washington."

"Do they have scientists at Washington?" asked Hennessy.

"They do that. Me frind says that moostly all iv th' raly progrissiv scientists ar' at Washington. Ye see, Hinnissy, scientists ar' jist like polytishuns; they ar' divided into pro-

grissives an' consarvitives. The progrissives want to see somethin' doin' avin av they have to do it thimsilves: th' consarvitives moost have ivrythin' quiet avin iv th' ithers want t' worruk."

"What do they do?" said Hennessy.

"They ask Congriss fer large appropia-shuns froom th' money that th' taxpayers iv th' coontry rejoice t' conthribute, fer th' perpus iv amelyoratin' th' rejuced condishun iv th' pore farmer."

"What ilse do they do?" asked Hennessy.

"I ferget t' ask," said Mr. Dooley, "but I know, be th' way me frind was wipin' th' sweat iv toil from his brow, that he is not wan who wud accept his small honyrarium from a ginerus an' grateful government without doobly arrnin' it. He had jist finished, be tremenjus la-a-bor, a monimental worruk showin' how anny farmer, be th' simple use iv a tilliscope an' siv'ral ither chemicals which have escaped me mim'ry fer th' moment, can ixamine a single grane iv wheat an' tell what farm it grew on."

"Why shud he want to do that?" said Hennessy.

"He don't," said Mr. Dooley as he relighted his pipe, "but it will amelyorate his rejuced condishun."

"But it was not this awful la-a-bor brot to a brilyunt conclushun that pre-e-juiced th' beads upon his fevered brow; it was th' great trooble he was havin' to kape th' science iv th' coontry upon 'th' plane to which it properly belongs,' as he said to me in toones iv great imotion. Says he: 'Iv'ry time I pick up me fav'rite jernul, *The Ixpirimint Stashun Ricord*, I am pained be th' use iv langwidge that I do not understand. There ar' worruds that I have always trated as me own chilther that wud no longer be ricognized be their own father.'

"Not wishin' to seem onint'risted I bro-o-ke th' pause in th' convarsashun be askin', 'Ain't there lots iv worruds with more than wan manin'?'"

"'In litherachoor,' says he with a savidge frown, 'which is a very diff'runt thing. In litherachoor such a thing is permisabul be-

cause only orthinary onint'ristin' persons read litherachoor. In science wan must be ortherly. Iv'ry scientist has an ortherly brain an' becomes confused in his finer sinsibilities av a worrurd has mo-ore than wan manin'. We shall have a law passed forbiddin' th' use iv anny worrurd in anny but the proper meanin'.

"How will ye know th' proper manin'?" says I, bein' somewhat puzzled.

"The proper manin' iv anny worrurd," says he, 'will be th' manin' which I and me brothers iv like int'rists and progrissiv ideas will give it.'

"Who are th' villuns who have bin committin' this abuse iv will intinshuned worruds?" I asked.

"They raly shud not be called scientists at all," says he, 'but sudo- or false scientists. They call thimselves "geneticists." 'Tis a worrurd that means an investigator in th' sudo-science iv heredity. But whin th' law is passed,' says he, 'twill be a name iv great approbrium.'

"I shud think the name wud be curse enuf," said I. 'But what is the precise branch iv th' great realm iv knowlidge that they st-thrive t' be settin' in orther? What is th' rale manin' iv it?'

"They ar' th' scounthruls," says he bitin' a large pace out iv a pincil he was holdin', 'that ixamine yer eyes an' th' eyes iv yer wife—an' th' eyes iv yer parents barrin' they ain't iscaped be dyin'—an' tell ye what color they will let th' eyes iv yer chilther be.'

"What av ye rafuse t' ixcipt th' color they pick out fer ye," says I.

"Ye have to," says he.

"The villuns," says I agin, fer be this time I was beginnin' t' see th' foul plot against th' liberties iv our great nashun. 'It must be stopped.'

"It will be," says he. 'Ler goose a broila, as that prince iv awthirs Bill Shakespere or soome wan ilse has so will said. No more will they be allowed to fill th' chicest jernuls wid mistakes, conthradicshuns and maledicshuns concarnin' mathematics iv which they know nawthin', an' concarnin' beollergy av which they know less.'

"But don't all conthribushuns to th' larned jernuls soometimes contain mistakes?" says I.

"All but those iv meself an' a few ithers," says he.

"How do ye manage it?" says I.

"We don't conthribute annythin'," says he.

"Have ye spoken to me mind Doc Wiley about this attack upon th' bulworrucks iv a great people?" says I.

"I have written him th' full details," says he, 'but I'm afraid he has proved false to th' thrust th' people have reposed within him.'

"What did he say?" I ixclaimed in horror.

"Here is his letther," says he.

"My Dear Sir: I fear yer liver is out iv orther. I wud advise you to take Hg,Cl₂ wantin' grain iv'ry fifteen minits fer four hours. N. B. Be sure an' rimimber the 2 afther the Hg, fer anny misuse iv sich a worrurd or char-achter might cause wan iv yer inimies t' be indited fer yer desace."

"Wud he pisen ye?" says I.

"I don't know," says he, 'I didn't take it.'

"I'm not sure that I know what it's all about," said Mr. Hennessy, "but it must be a grand thing t' be a raly great scientist. I shud like to be wan."

"Fergit it," said Mr. Dooley, "th' great wans ar' all dead."

A. P. SEUDO,

With apologies to P. F. Dunne

SCIENTIFIC BOOKS

RECENT BOOKS ON THE DOCTRINE OF DESCENT

La genèse des espèces animales. By L. CUÉNOT. Paris, Felix Alcan. 1911.

Allgemeine Vererbungslehre. By V. HAECKER. Braunschweig, Friedr. Vieweg und Sohn. 1911.

Heredity in Relation to Evolution and Animal Breeding. By WILLIAM E. CASTLE. New York, D. Appleton & Co. 1911.

Upon the Inheritance of Acquired Characters. By E. RIGNANO. Authorized English translation by BASIL C. H. HARVEY. Chicago, Open Court Publishing Co. 1911.

These four books have one feature in common, namely, they all deal with problems

which lie at the base of the doctrine of descent. But while they present this similarity they also differ greatly in their scope and manner of presentation, the first covering the broader field of the origin and adaptation of species, the second reviewing carefully and thoroughly our present position with regard to the fundamental facts and theories of heredity, the third presenting in a more popular manner the principles of Mendelian inheritance, while the last is an exposition of a new theory of heredity.

Professor Cuénot's book is one of the International Scientific Series, and in many ways it recalls one of the same series published thirty years ago and still a treasury of pertinent facts for the modern zoologist, Semper's "Animal Life." It endeavors to present impartially the important facts upon which the conclusions of zoological investigation are founded, rather than a minute exposition or criticism of these conclusions. The first part is a brief statement of the growth of the doctrine of transformism and to this succeeds a study of the phenomena of reproduction, form regulation and correlation, animal behavior and sex differentiation, and finally, the duration of life of the individual is considered.

The third part is devoted to the conditions under which variation of the individual occurs, under which heading are considered the phenomena of mutation (the Mendelian phenomena being included under that caption), the non-inheritance of acquired characters and selection, and then follows a fourth part devoted to geographical distribution and the faunistic characteristics of the various milieux, marine, aquatic and terrestrial. In this part one finds brief, interesting discussions of the planktonic, littoral and bathysinal faunas, together with those of brackish and supersaline waters, mountain regions and caves and, finally, there is a brief discussion of commensalism and parasitism. The fifth and last part presents, first, a brief statement of the doctrine of panspermia maintained by Montivault and Arrhenius, and proceeds with a discussion of the origin of species and adaptations in which such phenomena as iso-

lation, parallelism, polymorphism, regression, protective and warning coloration and mimicry are illustrated by well-chosen examples. A brief exposition of the views of Lamarck, Darwin, Eimer, Weismann and the post-Darwinian schools rounds out a satisfactory concrete exposition of what may be termed the principles of general zoology. Notwithstanding the conciseness necessary in a work covering so wide a territory the book is most readable and interesting, and, with its extraordinary wealth of well-chosen examples and its abundant illustrations, will prove a boon both to the teacher and the student of general zoology.

Haecker's "Allgemeine Vererbungslehre" has more of an academic character, being the outcome of lectures delivered by the author in past years at Stuttgart, Hohenheim and Halle, and will be welcomed by professional zoologists as a thorough scientific exposition of our present knowledge of the underlying principles and laws of inheritance. Starting with a brief historical section, in which Galton's law is discussed, the morphological bases of heredity are considered with a thoroughness and clearness that are admirable, the author's experience with cytological phenomena as seen in copepodan germ cells rendering him especially at home in this part of his subject. Of especial interest are the discussions of heterotypic mitoses and heterochromosomes and of the significance of the number of chromosomes. The third section is of a more theoretical nature, being devoted to a review of Weismann's hypotheses and Hertwig's theory of biogenesis.

The fourth section is a return to the descriptive side of the subject, the phenomena of Mendelian inheritance being under consideration, and receiving a remarkably clear presentation, excellently illustrated. In the concluding section theoretical considerations, such as the individuality of the chromosomes, the reduction division and the determination of sex are again prominent, and the last chapter is devoted to the discussion of a Kernplasma theory of heredity to replace the chromosome theory.

Haecker's book by reason of its thoroughness and scientific method of exposition will undoubtedly be to a large extent caviare to the general, but that by Castle will appeal to a much wider circle of readers as a clear and direct statement of the Mendelian principles and their application, couched in language as simple and untechnical as may be. Its title, compared with that selected by Haecker, is perhaps a little misleading, for the book is limited to an account of the Mendelian phenomena and their formal explanation. The cytological side of inheritance, so prominent in Haecker's book, is barely considered; indeed, it could hardly be expected in a book written for the general reading public. Taking into account the limitations set by its purpose, the book is an excellent presentation of the Mendelian phenomena, based upon studies extending over some ten years, and while the general reader may in some cases find it difficult to follow the complexities of the phenomena, yet he will not fail to form an intelligent appreciation of the far-reaching significance of Mendelism.

But it is not to the lay brother alone that the book will prove of interest. The expert will find much to interest him in its logical methods and in the *résumé* it presents of extensive experience in experimental breeding, and in certain of the chapters, such, for instance, as those on Mendelism and Selection and on Heredity and Sex, he will be rewarded with no scanty supply of food for thought.

Rigano's work appeared in a French edition as long ago as 1907 and an abstract of it by the present translator was published in *The Monist* in 1909. It is an attempt to formulate a new theory of heredity based on analogy with certain electrical phenomena. The theory of centro-epigenesis, as it is named, assumes the existence in the germ plasma of certain specific potential elements, which send out in succession through the organism impulses which determine the various stages of its ontogeny, each specific impulse depositing in the nucleus of the cells to which it passes a definite substance, which, under similar con-

ditions is again capable of producing the same specific impulse as that by which it was deposited. When ontogenesis is complete the organism is in a state of dynamic equilibrium so far as the epigenetic impulses from the germ plasma are concerned, but it is now receiving functional stimuli, which in a similar manner produce specific impulses leading to the deposit of what may be a new kind of material. If the stimulus reaches the germ plasma new specific potential elements will be deposited in it and so the way is open for the inheritance of acquired characters.

This is a bald statement of the essentials of the theory which is fully elaborated and compared with rival theories in the volume under consideration. Similarities with Semon's theory of mnemes suggest themselves, and like this the theory can truthfully be said to be exceedingly suggestive. But if criticism may be made without entering into details, it would seem that centroepigenesis explains almost too much, in furnishing possibilities for the inheritance of acquired characters far beyond what reality demands. It is based on assumptions which at present we have no means of either proving or, what is much more difficult, disproving, assumptions drawn from what is not always a reliable source, namely from analogy. But right or wrong, it should serve to suggest lines along which the further investigation of the physiology and physics of the developing organism may advantageously proceed.

The translation, it should be stated, is well done and the translator is to be congratulated on having supplied English readers with an accurate and readable statement of the theory.

J. P. McM.

Nephritis, An Experimental and Critical Study of its Nature, Cause and the Principles of its Relief. By DR. MARTIN H. FISCHER. (The 1911 Cartwright Prize Essay of the Association of the Alumni of the College of Physicians and Surgeons, Medical Department of Columbia University, New York.) First edition, large 12mo. Pp. ix + 203;

31 figures, including a colored plate. Cloth, \$2.50 net. New York, John Wiley & Sons. 1912.

In this book Fischer has made a special application to the kidney of the same standpoint, principles and methods as were used in the more general discussion contained in his work on edema, published two years ago. According to his view it is to the colloidal properties of albuminous substances, and particularly of such bodies in the *gel* state, that we must look for an explanation of many phases of the behavior of living cells, not only in health, but to an equal degree in disease. In particular the amount of water contained within every cell, *i. e.*, its turgescence, and the extent to which the cell membrane dissolves, passing from the *gel* to the *sol* condition in the surrounding fluids, are determined by the properties peculiar to colloids. These properties, as we find them in the so-called emulsion or lyophilic colloids to which all albuminous substances belong, include a specific avidity for water according to the conditions under which the colloid is placed. Thus if a piece of dry sheet gelatin is placed in water at an ordinary temperature it swells—that is, imbibes water—to a fairly definite degree. Similarly in the *sol* condition, as in the case of the proteins of the blood plasma, the water in which they are said to be “dissolved” is really held by the colloid. Otherwise the tissues of the body should immediately imbibe all of the blood fluid as they do saline or Ringer’s solution. The avidity of the colloids for water is, however, subject to great alterations according to the surrounding conditions. Thus acids and alkalis both induce a markedly increased degree of swelling as compared with a neutral watery medium, while salts, on the contrary, tend to decrease the capacity of colloids to take up and hold water. As the result, in particular, of the work of L. J. Henderson it is now known that the normal blood is not only neutral in reaction, but that it has a remarkable capacity to maintain its neutrality against the introduction of considerable quantities of acids or alkalis. Under the influence of toxic substances, or under conditions in which the

circulation is interfered with, a formation and accumulation of acids within the tissues of an organ does, however, occur. This is particularly the case in an organ which, like the kidney, has normally a large respiratory exchange.

Boldly following this conception to its conclusion Fischer holds that “all the changes that characterize nephritis are due to a common cause—the abnormal production or accumulation of acid in the cells of the kidney. To the action of this acid on the colloidal structures that make up the kidney are due the albuminuria, the specific morphological changes noted in the kidneys, the associated production of casts, the quantitative variations in the amount of urine secreted, the quantitative variations in the amounts of dissolved substances secreted, etc.” In support of this thesis experiments are reported in which a typical cloudy swelling was induced in thin sections of fresh kidney tissue when placed in dilute acid. Similarly in experiments upon animals injection of acid into the blood stream is quickly followed by a marked albuminuria. The same result follows temporary ligation of the renal blood vessels. On the other hand—and herein, perhaps, lies the most important points of Fischer’s investigations—if under conditions in which nephritis would otherwise occur an increased quantity of neutral salts is brought into contact with the tissues, the effects of acid may be completely counteracted, and the kidney restored to practically normal structural appearance and functional behavior. Thus, “Sodium chloride when injected intravenously, in concentrated solution, simultaneously with hydrochloric acid solution of a concentration which we found in other experiments to lead to the symptoms of a most intense acute nephritis, practically suppresses this entirely. The albuminuria scarcely appears, and there are no casts, no red blood corpuscles, no hemoglobinuria, no decrease in the amount of urinary secretion, and no general edema.” Finally Fischer reports a number of clinical cases of nephritis, some of them with complete anuria and coma, in which a rapid recovery was in-

duced by the administration per rectum of a solution of NaCO_3 and NaCl .

From the foregoing outline it will be seen that this book is in no sense the conventional restatement of pre-existing data and current opinions. On the contrary, it is a highly original thesis. From those hide-bound critics, who resent whatever is unorthodox, it will probably elicit more dissent than approval. This has always been the price exacted by such critics from those who are ahead of their time. They objected to Fischer's preceding work on "Edema" on the ground that "there are some facts which it fails to explain." They will find that the same criticism can be made of the present monograph. There are indeed some points in the book upon which one must hope that the author will later bring forward fuller evidence. Nevertheless, if, as seems but fair, a new idea is rather to be approved for the points which it illumines than condemned for those which it leaves in obscurity, this work should be welcomed and studied. It holds out suggestions which may prove of great practical therapeutic usefulness. On the theoretic side there is a wide range of phenomena, previously obscure, upon which it throws a brilliant light.

YANDELL HENDERSON

An Experimental Study of the Death-Feigning of Belostoma (= Zaitia Aucet.) flumineum Say and Nepa apiculata Uhler. By HENRY H. P. SEVERIN, Ph.D., Professor of Entomology, College of Hawaii, and HARRY C. SEVERIN, M.A., Professor of Entomology, South Dakota State College of Agriculture and Mechanic Arts. Cambridge, Boston, Mass., Henry Holt and Company. 1911. Pp. iii + 47, with one plate.

This excellent piece of experimental work forms one of the series of "Behavior Monographs," that are being published in connection with *The Journal of Animal Behavior*, being Number 3, Serial Number 3, Volume I.

There is, perhaps, no more curious and interesting form of instinctive response than that represented by the death-feigning reac-

tion among insects. It has been a matter of considerable discussion among students of animal activities for many years. There has been no piece of work of this nature published for some time which so thoroughly treats of this peculiar form of behavior, by the experimental method—unless we consider that of Holmes on *Ranatra*.

The major headings of the table of contents will largely indicate the nature of the monograph: I., Introduction; II., General Characteristics of the Death-Feint; III., Duration of Successive Death-Feints; IV., The Effect of Dryness and Moisture on the Duration of the Death-Feint; V., The Effect of Temperature on the Duration of the Death-Feint; VI., The Effect of Light on the Duration of the Death-Feint; VII., The Effect of Mutilation on the Death-Feint; VIII., The Origin and Development of the Death-Feint; IX., The Psychic Aspect of the Death-Feint; X., Summary.

II. It is shown that the "death-feigning" postures of *Belostoma* are decidedly characteristic. However, the positions assumed during the feint are unlike those of the dead insect. The response may be elicited by simple contact; as, for instance, when it is dipped out of the water with the net; or when it is picked out of the aquarium by hand. Some individuals do not feign death readily; in such cases, repeated touching of the posterior part of the abdomen will cause the organism to respond with the death-feigning reaction. *Nepa* feigns death either in the water or out of it. Here again contact seems to be the important stimulus. *Nepa* will even feign death when feeding, the creature "keeping the styliform mandibles and maxillae sunk into the prey." Detailed descriptions are given of the positions of the various appendages during the feint, both in the case of *Belostoma* and *Nepa*. While the former assumes a characteristic posture, *Nepa* will feign death with the appendages in the same position as taken just previous to the death-feint. During the feigning period, the muscles of *Belostoma* are in a condition of "extreme tetanus." *Nepa*

may be held by any tibia or femur in such a manner that the weight of the entire insect is sustained by the extensor muscles of an individual segment of one leg. In the case of *Nepa* many interesting details are given concerning preliminary movements immediately prior to the termination of the feint. If *Belostoma* is mutilated by snipping off small portions of the appendages, the animal quickly comes out of the death-feint after one or two repetitions of the excision. *Nepa* acts quite differently. The legs may be cut off one at a time, and even the tip of the abdomen, without any movement on the part of the organism.

III. It was found that the duration of the feint varies considerably in different individuals. One group of *Belostomas* were put into thirty-eight death-feints; after this they refused to respond. After having been placed in water for a few moments, they again displayed the reaction. This was repeated again and again until the insects no longer feigned death. "The average time that all of the *Belostomas* feigned throughout all the series of successive death feints was eight hours." In other experiments, it was found that the responses, in both *Belostoma* and *Nepa*, became weaker toward the end of the series; also that the duration of the death-feint decreased in a succession of trials; and that the cause of the cessation of the response, in each series of experiments, while partly due to fatigue, was more largely the result of the dryness of the body while exposed to the air.

IV. Dryness tends to decrease and dampness to increase the length of the death-feint. If *Belostoma* is placed upon the surface-film, or below the water surface, the duration of the feint is diminished. When *Belostoma* is thrown into the water, it usually comes out of the death-feint immediately. Sometimes, however, the creature will bob up to the surface of the water and feign in that position.

V. The duration of the death-feint diminishes in both species when exposed to high temperatures. At a low temperature the response is lessened in *Belostoma*. In *Nepa*, on

the other hand, a low temperature prolongs the death-feint. These facts were ascertained while the insects were exposed to the atmosphere. Experiments were also undertaken with the view to discover what the result would be on the death-feigning reaction when the animals were transferred from water to the atmosphere. It was found that the duration of the feint is lessened when the transition was from water at a low temperature to the atmosphere with a temperature lower than 12° C. In both *Belostoma* and *Nepa* the death-feint considerably decreases at a low temperature.

VI. If *Belostomas* are exposed to sunlight the length of the death-feigning reaction diminishes. In certain experiments with artificial light it was discovered that both *Belostoma* and *Nepa* are aroused more quickly when subjected to a bright light than was the case with a weak light. A moving light arouses both species sooner than a stationary one. The death-feint in *Nepa* is much diminished when the creature is exposed to a bright light, if the organisms had previously been kept in the dark.

VII. The authors call attention to the work of Robertson on spiders, *Epeira producta*? and *Amaurobius* sp.? This author found that the "sham-death" reflex may be induced in the above active species "by the thoracic ganglia alone, or even by the ganglia of the posterior or two anterior segments of the thorax alone. . . . With the supra- and sub-oesophageal ganglia removed the reaction is still carried out in the active species, but it is now weaker, has a longer latent period (in *Epeira* sp. at least, and probably in *Amaurobius* sp.) and it is a rhythmically interrupted tetanus." In this same connection the work of Holmes on *Ranatra* is quoted. If the head of *Belostoma* is removed with a pair of sharp scissors, the creature generally continues to feign death. Decapitated specimens will often swim freely in the water after arousing from the feint. On removing the supra-oesophageal ganglion most of the organisms continued the death-feint; but the usual tension of the body and

appendages was very much weakened. "With those decapitated *Belostomas* that assumed the death-feigning attitude, a weakened tetanic condition of the muscles could be induced by gently stroking the abdomen with a camel's hair brush, but the instant the stroking ended the legs would sprawl apart and become lax." Certain experiments were performed by the authors in which the *Belostomas* and *Nepas* were cut into two distinct parts, the cut being made between the prothorax and the mesothorax. The operation was performed in such a manner that "neither the fused infra-oesophageal and first thoracic ganglia, nor the large ganglion, which innervates the posterior pairs of legs and the abdomen, are injured." In such cases, in *Belostoma*, the two parts continued to feign death. In fact the response continued for a considerable length of time after the operation. The posterior portion, after coming out of the death-feint, if thrown into water, would attempt to swim by making a few feeble movements with the appendages. When the water bug, *Belostoma*, is severed between the first two thoracic segments, the two portions will continue the feigning posture; yet when the head is removed, the organism immediately arouses from the death-feint. In other cases the insect (*Nepa*) was severed across the metathorax, posterior to the last ganglion, and it was found that the posterior portion did not respond to stimuli at all even when the ventral surface of the abdomen was touched with a red hot needle; but the part in front of the cut reacted much in the same manner as an uninjured specimen.

VIII. In the discussion of "The Origin and Development of the Death-Feint," the authors review the ideas of Preyer, Romanes and Holmes. They call attention to the fact that both *Belostoma* and *Nepa* tend to cling together and form clusters, a positively thigmotactic response. It is also a noticeable phenomenon that contact stimuli play a large rôle in the lives of both of these organisms. "The various members of the families *Belostomidae* and *Nepidae*" are largely responsive to touch stimuli. The authors believe that the

phenomenon of death-feigning may have its origin "out of positively thigmotactic propensities."

IX. The authors do not believe that in the lower animals there is any conscious effort to deceive their enemies through the death-feigning response. They consider that the act is an instinctive one. There is no room for the supposition that the response is anything more than a non-intelligent one. "The death-feint in the arthropods is simply a non-intelligent instinctive act."

URBANA, ILL.,

November 14, 1911

The Sun. By CHARLES G. ABBOT. D. Appleton & Co. 1911. Pp. xxv + 448, illustrated.

Upon the steady and regular maintenance of the amount of heat received by the earth from the sun depends the very existence of life upon our planet. Any large variation in the amount of solar heat would totally destroy the world as it is to-day, would make it an uninhabitable furnace or a frozen waste of icebergs. This dependence upon the life-giving properties of the sun has been dimly realized from the earliest times; in many lands and in many ages the sun has been worshipped as the all-powerful, the god of gods. Yet it is only within comparatively recent years that anything has been known as to what the sun really is, and whence is derived its constant outpourings of light- and life-giving energy. A hundred years ago, so little was known about heat and its properties that the elder Herschel could advance his fanciful and utterly impossible theory of a habitable sun.

To within the last three or four years widely divergent views have been held as to how much heat (radiant energy) reaches the earth from the sun in a given time. The younger Herschel in 1838 made the first scientific estimate of the quantity of heat derived from the sun. He found that a beam of sunlight three inches in diameter would raise the temperature of half a pint of water 0.37 of a degree per minute, or, were the sun in the zenith, the amount of heat received would

melt a coating of ice one inch in thickness in two hours and a quarter. Langley, about 1880 devised the "bolometer," an electrical thermometer so delicate that differences of temperature of less than one hundred-millionth of a degree can be detected. This instrument, as perfected and used by Langley and Abbot, has revolutionized the methods of studying the character and amount of heat received from the sun. The latest researches of Abbot and the Smithsonian Institution show that if the sun's rays could be completely employed to melt ice they would suffice to melt a coating one inch thick in one hour and thirty-eight minutes, or a layer 426 feet thick in a year.

Abbot's book is a study of the latest researches on the light and heat of the sun, of the sources from which that body derives its apparently inexhaustible supply of energy, and of the methods and instruments by means of which the great advances in knowledge have been made. It is a book by an active and successful worker in the field of solar investigation, a particularly sane and successful worker. The simple astronomical facts regarding the size, shape and distance of the sun, the phenomena of the visible surface, the rotation and the spots, are reviewed at length, but the feature of the book is the exhaustive treatment of all questions connected with the sun's action as a fountain of light and heat.

As to what the sun really is, Abbot is a strong advocate of the theory of a purely gaseous body (except sun spots). That the sun is mainly gaseous has been the accepted theory, but most writers and investigators have considered the visible surface as semi-fluid, as a sort of cloudlike formation floating in the outer gaseous envelopes. Sunspots are regarded by Abbot as cyclonic storms, or vortices, similar in form to water spouts seen at sea, the whirl carrying gases from below upward. The rapid uprush of the gases and the spreading out into the trumpet shape top, cause a rapid expansion and great cooling. This cooling carries the temperature down, and allows the formation of liquids, and thus the spots may be cloudlike forms, with some

liquid and even solid particles. The peculiar periodicity of the spots in number and size is as yet unexplained. As to the source of the sun's heat and energy, Abbot shows that we may still regard Helmholtz's contractive hypothesis as adequate to satisfy the requirements of geology and physics. He is not carried off his feet by the popular scientific craze of explaining everything as a phase of radio-activity. Radio-active processes may have contributed somewhat to the store of solar energy, but that they have been any appreciable factor has not yet been shown.

The book is well written and is full of interesting matter for the scientist and for the general student. In it are tabulated and brought together the results of many researches, some hitherto unpublished, and others only to be found in special journals; the various hypotheses of solar physics are clearly set forth, and the merits and defects of each explained. It is the best work on the subject that has appeared for many years and will rank with and take the place of the similar book, by the late Charles A. Young, which for so many years was regarded as the standard treatise on "The Sun."

DECIDUOUS ROOTLETS OF DESERT PLANTS

A STUDY of the roots of many perennials and of a few annuals growing under arid conditions in the Tucson region, shows that there are two sorts of rootlets which, to a degree, have similar functions, but which usually have an unlike fate. Whether analogous plants of the more moist regions have similar rootlets is unknown to the writer. A characterization of the rootlets in question can be made by describing those of a typical shrub, such as *Franseria deltoidea*, and by referring to analogous rootlets of some of the annuals.

In *Franseria* the tips of the main roots end in a brush of slender rootlets which bear root hairs. Most of these terminal rootlets are formed during the moist seasons, generally summer, and die during the following dry season, but some survive to extend the root-system. Such rootlets are found on the most deeply penetrating, as well as the most shallowly placed roots. But on the more superficial roots only there is, in addition, another type of rootlet. These are filamentous, 2 cm., more or less, in length, in groups of about one half dozen, which occur from 2 to 4 cm. apart. They arise from older roots only, and hence are adventitious. Since these rootlets are formed during the moister seasons each year, and die during the succeeding dry season, and never, or almost never, persist to form permanent roots, I have referred to them as deciduous.¹

The deciduous rootlets, as before suggested, are found on roots which are placed near the surface of the soil. From this fact, and from the known variation in water content of the superficial soil horizon, it is assumed that the deciduous rootlets are perhaps the first absorbing organs, after the beginning of the rainy season, to function. Also owing to the fact that the superficial soil layers are the first to become desiccated, it is assumed that the deciduous rootlets cease activities before the

other type referred to. It is probable, therefore, that the deciduous rootlets are of great importance in providing water absorption surface during the time of maximum, or optimum, water supply, and that the second type of rootlets in deeper soil, lingering longer, serve to provide the plant with water during a longer period, probably until the next season of precipitation.

Undoubtedly an important factor in the physiology of water absorption, and in the water relation, generally speaking, is that of the distance of water transport. Where the distance from the point of absorption to the place of evaporation is great it is probable that a given amount of water is less efficient in a longer than in a shorter transport. We have, in the formation of the deciduous rootlets, the interesting condition that the water absorption surface is enormously increased without at the same time increasing the distance of water transport. The importance of this in the physiology of the plant will appear at a glance.

Nearly all perennials which have been examined are provided with deciduous rootlets. It is not supposed, however, that these rootlets are essentially different from the other type, although they have a different origin, and although they appear to have a somewhat different function. From a few instances it has been seen that permanent roots may be derived from groups of rootlets which probably were indistinguishable from the deciduous rootlets, but which were so fortunately placed that survival was possible.

An analogous condition, but naturally differing in many ways, is to be found in the root-systems of several desert annuals. In such forms, in addition to the usual and, of course, ephemeral absorbing roots, there are at the base of many laterals rudimentary rootlets. These may remain rudimentary, never developing, or if the moisture conditions favor, they may develop. Where such rootlets are not found, it seems from certain experiments that they can not easily be induced. Probably the greatest advantage to an annual bearing rudimental rootlet is that

¹"The Root Habits of Desert Plants," W. A. Cannon, Carnegie Institution of Washington, Publication No. 181, 1911.

should there be a return of rains, following a rainy season, so soon after the rainy season that the annuals are still living, the rudimentary roots quickly develop, enabling the plant to complete its growth, or to renew it. The matter of distance of water transport in the annuals would hardly come into the problem.

W. A. CANNON

DESERT LABORATORY

THE EFFECT OF NARCOTICS UPON THE DEVELOPMENT OF THE HEN'S EGG

ONE of the evident difficulties experienced in experimentation with the eggs of birds is that due to their large size, which makes it impossible to use the large numbers of eggs that may be handled in the case of fishes or amphibians. Also, while it is usually possible to obtain eggs at any season of the year, if one be willing to pay the price, the percentage of infertile eggs is usually so high except during the spring that the time for profitable experimentation is quite limited.

The experiments here described are of a purely preliminary nature. It is the purpose of the writer to continue the experiments until the number of eggs used will justify some general conclusions.

The reagents used were alcohol, ether, chloroform, chlorotone and magnesium chloride. One or two of these proved so almost universally fatal in their effects that they will probably not be employed in further experimentation.

Alcohol.—This reagent was employed as follows: the eggs were placed in the incubator and left for a number of hours (five to seventeen, in different experiments); they were then placed in a glass specimen jar having a glass cover, with raw cotton wet with from 1 to 5 c.c. of 95 per cent. alcohol; the jar was covered and replaced in the incubator, where it was left for from three to twelve hours, after which the eggs were removed from the atmosphere of alcohol, thoroughly aired and replaced in the incubator (which had also been aired) for about forty-eight hours before being opened. The glass jar was of about 1,200 c.c. capacity, and not more than eight

eggs were placed in it at once, so that there was a considerable volume of air for each egg. When the lid was removed, to take the eggs from the jar, there was always a strong smell of alcohol.

Of the eggs treated in this way only about 25 per cent. contained living embryos when opened. About half of the embryos obtained from these eggs were abnormal to a greater or less extent. The character of the abnormalities will be described when further experiments have furnished more material.

Ether.—The experiments with ether were conducted in the same general manner as those with alcohol, except that, as a rule, only 1 or 2 c.c. of ether were used.

The effect of ether seemed to be much less severe than that of alcohol, only about 35 per cent. of the embryos being killed. Of the embryos removed from the eggs, less than half were abnormal.

Chloroform.—Chloroform was employed in the same manner as was ether, and, while fewer experiments were tried, not a single egg, opened after being submitted to this reagent, contained a living embryo, showing that it is much more toxic in effect, under these conditions, than either alcohol or ether.

Chlorotone.—This reagent was employed as a .1 per cent. solution in distilled water. In one experiment the eggs were kept in the incubator for ten hours before introducing the chlorotone; in the other experiments the chlorotone was introduced into the fresh egg. The method employed was to carefully remove about a square centimeter of shell from the side of the egg, and, with a clean glass tube, blow out about 5 to 10 c.c. of the albumen, without touching the yolk; the space thus made was filled with the reagent; the opening was then sealed with a piece of fresh shell, with strips of shell membrane stuck around the edge with some of the albumen that had been blown out of the egg. This is the method of closing an incubating egg used by Miss Peebles.

This treatment proved fatal to more than 90 per cent. of the embryos, but a few control experiments, where the eggs were opened and

sealed again without introducing any foreign substance, gave such a large percentage of fatalities that too large a percentage of fatalities in the experiments proper should not be attributed to the reagent.

Magnesium Chloride.—The magnesium chloride was employed as a 10 per cent., 16 per cent. and 33 per cent. dilution of the molecular solution of the salt in normal salt solution; that is to say, ten parts of the molecular solution of magnesium chloride were diluted with ninety parts of normal salt solution; etc.

The reagent was introduced into the eggs in the same manner as was the chlorotone; in some cases into fresh eggs, in other cases into the eggs after they had been in the incubator from ten to twenty hours.

The effect of these weak magnesium chloride solutions was about the same as the chlorotone, the embryos being killed in practically every case, or, at least, the process of incubation was inhibited. As in the case of chlorotone the results were here largely vitiated by faulty technic in opening and closing the eggs for the introduction of the reagent.

These preliminary experiments, as has been said, while too limited in number to give definite results, will serve as a guide for further work, especially in regard to the character and strength of reagents and the length of time they should be allowed to act.

INHIBITION OF CELL DIVISION IN PARAMÆCIUM

IN connection with the discussion of "potential immortality" in Protozoa (in other words, their ability to continue their physical existence indefinitely, barring accident and disease, through the bodily "splitting up" of each individual into its two offspring, each repeating the process, which is continued "*ad infinitum*") it may be of some interest to note the length of time an individual has been observed to maintain its identity—in other words, to continue living, without dividing into its progeny. The writer has suc-

ceeded in preventing one specimen of *Paramæcium caudatum* from dividing, for the space of a little over thirty-two days, by keeping it confined in capillary tubes of bores too small to permit it to turn back readily.

Control specimens had meanwhile divided on an average of once a day. In other words, if the confined specimen had been allowed to divide unmolested, it would have divided into four billion, two hundred and ninety-four million, nine hundred and sixty-seven thousand, two hundred and ninety-six offspring!

The irritation caused by the confining walls is doubtless a factor of as great importance as the accumulation of the products of excretion, and the lack of nutrition; since specimens which were daily taken from their tubes and allowed to swim about in a fresh infusion containing an abundance of *Bacterium termo*, for a number of hours before being transferred to new tubes, nevertheless refused to divide.

Particles which appear to be cast-off portions of the specimen's body, were frequently observed in the tubes with individuals thus treated, thus suggesting that increase of protoplasmic bulk may take place without the customary sequence of cell division, even in well-nourished individuals.

Conklin's observations on *Crepidula* seem to indicate that the dwarfing of those forms in small hermit crab shells (dwarf forms being always found in small hermit shells, and "giant" forms in large hermit shells) is due to an inhibition of cell division, since the difference in size is due to the difference in the number of cells, rather than to differences in cell size. Crustacea, Echinodermata, Mollusca, Amphibia, etc., reared in small vessels are always dwarfed, and this too must be due to an inhibition of cell division.

In the case of *Crepidula*, the fact that the hermit shells are open to the ocean would indicate that the accumulation of waste products, and lack of proper nutrition can hardly be regarded as a sole, or even the chief, cause of this inhibition of cell division, and the writer is inclined to the opinion that narrower confinement in some way acts as an important factor in the process.

If a dwarf *Crepidula* be removed from a small hermit shell, and find lodgment elsewhere, it is readily seen that the inhibitory influence was merely temporary, since the dwarf then grows to the normal size. So too the confined *Paramœcium*, after being liberated, soon begins the process of fission at the normal rate.

A more detailed account of these experiments, together with some observations on the behavior of Protozoa confined in capillary tubes, will shortly appear in another publication.

SOCIETIES AND ACADEMIES

THE MICHIGAN ACADEMY OF SCIENCE SECTION OF ZOOLOGY

THE zoological section of the Michigan Academy of Science met at the University of Michigan, March 28. Mr. Peter Okkleberg was chosen president for the coming year. The following program of papers was presented:

"Results of the Merston Expedition to the Charity Islands, Lake Huron, Amphibians and Reptiles," Crystal Thompson and Helen Thompson, Ann Arbor.

"Some Bird and Mammal Records for Michigan," N. A. Wood, Ann Arbor.

"Directions for Collecting and Preserving Specimens of Reptiles and Amphibians for Museum Purposes," Alexander G. Ruthven, Ann Arbor.

"The Breeding Birds of the Charity Islands, Lake Huron, with Additional Notes on the Migrants," N. A. Wood.

"On the Wisconsin Wood-frog," Helen Thompson.

"The Pickerel Frog, *Rana palustris* LeConte, in Michigan," Crystal Thompson.

"External Conditions and the Growth Period in the Eggs of *Hydatina senta*," A. F. Shull, Ann Arbor.

"The Influence of Egg and Sperm in Inheritance of Egg Characters in *Hydatina senta*," A. F. Shull.

"The Origin of Continental Forms, 3. A Preliminary Note on Faunal and Floral Relations," Howard B. Baker, Detroit.

"A Collection of Mammals from Osceola

County, Michigan," Orrin J. Wenzel, Ann Arbor.

"The Mouth Reflex of Physa: May it be Substituted for the Salivary Reflex of Pawlow in Studies of the Nervous System of Snails?" Elizabeth Thompson, Ann Arbor.

"Pseudohermaphroditism in the Brook Lamprey," Peter Okkleberg, Ann Arbor.

"Factors that Determine the Location of the Borings of the Yellow-bellied Sapsucker in the Yellow Birch," Margaret W. Taggart. (Presented by Jacob Reighard.)

"Report on the Zoological Work done at the Biological Station of the U. of M. at Douglas Lake," Jacob Reighard, Ann Arbor.

"Cestode Parasites of Fresh-water Fish," George R. La Rue, Ann Arbor.

"New Methods of making *in toto* Preparations," George R. La Rue.

"The Distribution of the Ancyliidæ," Bryant Walker, Detroit.

"Preliminary Report on the Ecology of the Mollusks of the Douglas Lake Region," H. Burington Baker, Ann Arbor.

"The Origin of the Germ Cells in the Toad Fish," Emory Sink, Ann Arbor.

"The Application of Calorimetric Methods to the Study of Embryology," O. C. Glaser, Ann Arbor.

"Notes on the Amphibia and Mammals of Gratiot County, Michigan," H. M. MacCurdy, Alma.

"Check-list of Michigan Lepidoptera. I. Rhopalocera (Butterflies)," W. W. Newcombe, Detroit.

"Some Observations on the Muskrat Houses near Ann Arbor," F. C. Gates, Ann Arbor.

"On some Amphibians and Reptiles from the State of Vera Cruz, Mexico," Alexander G. Ruthven.

GEORGE R. LA RUE

UNIVERSITY OF MICHIGAN

THE HELMINTHOLOGICAL SOCIETY OF WASHINGTON

THE tenth regular meeting of the society was held at Dr. Stiles's residence on March 14, 1912, Dr. Stiles acting as host and Mr. Crawley as chairman. The receipt of a set of author reprints from Dr. Arthur Shipley for the society's library was noted.

Dr. Stiles reported that the Index-Catalogue of Medical and Veterinary Zoology dealing with the subjects Cestoda and Cestode Diseases, by Stiles and Hassall, was now in manuscript ready for

press. He also reported that he had in preparation a list of the names of all hookworms.

The secretary read the following communication from Dr. Fritz Zschokke:

Gordius aquaticus L. as a Parasite of Man.

A two and one half year old boy at Dorentingen, a village near Solluthorn (Switzerland), passed per anum a male *Gordius aquaticus* L. about 17 centimeters long, together with several specimens of *Oxyuris*. After passage, the worm lived three days free in water. According to the attending physician, the patient was subject to nervous troubles, which disappeared immediately upon the removal of the parasite. Symptoms involving the intestinal canal were present only to a slight extent.

Up to 1906, 9 authentic cases of the occurrence of *Gordius* in man were known. These occurred in Italy (3), France (3), North America (1), Bavaria (1) and Austria (1). To these must now be added the case reported from Switzerland. Most of the carriers of the parasites are boys and young people from two and a half to twenty-two years old. Systematically, the *gordius* forms found in human beings belong to the species: *Gordius aquaticus* L., *G. villoti* Rosa, *Paragordius varius* Leidy, *P. tricuspidatus* L., *Parachordodes tolosanus* Duj., *P. pustulosus* Baird and *P. violaceus* Baird.

The duration of the pseudoparasitic infection of the human intestinal canal by *Gordius* may extend over months; it is accompanied by the symptoms of a more or less clearly indicated helminthiasis which disappear with the discharge of the parasite by mouth or anus of the host individual.

Probably the infection takes place through the ingestion in drinking water of the free-living worms which have already passed through their parasitic developmental stage in insect larvæ and predaceous insects. Also, the patient at Dorentingen had the habit of drinking from a watering trough.

Gordius in the adult state is well fitted for a parasitic mode of living. Its strong chitinous covering protects the worm against the digestive fluids of the host. It is in a high degree insensitive to considerable variation of temperature, and also, as G. V. Bunge has shown, to the absence of oxygen.

Dr. Ransom presented the following note:

Cysticerci in American Sheep, Reindeer and Cattle.

Federal meat inspectors are frequently finding

sheep infested with cysticerci in the heart and voluntary muscles. These cysticerci closely resemble *Cysticercus cellulosæ*, which is said to occur occasionally in sheep, and they have been provisionally identified as such. The question as to their identity is now under further investigation, since it seems unlikely that so many cases of infestation would occur in sheep, especially in view of the fact that *Cysticercus cellulosæ* is comparatively rare in this country in hogs, the usual host.

Specimens of muscle cysticerci from Alaskan reindeer have recently been received by the Bureau of Animal Industry from Dr. D. S. Neuman, of Nome, Alaska, who reports that they are very common. These cysticerci have been provisionally identified as the cysticerci of *Tænia krabbei*, a tapeworm of the dog, although in some respects they do not correspond to the available descriptions of the cysticercus of that tapeworm.

There have also been some unusually high percentages of infestation of cattle with *Cysticercus bovis*. Three lots of cattle of 251, 70 and 201 head, originating in the same locality, had 25, 41 and 39 head, respectively, infested with this parasite.

Dr. Garrison reported that in an examination of a slide of some old human feces he had found an egg of *Fasciola*, apparently *F. hepatica*, together with a number of other parasite eggs, including a lateral-spined *Schistosomum* egg. He noted that Ashford has reported finding this egg in human feces in Porto Rico.

In comment, Dr. Stiles reported that he had an adult specimen of *Fasciola* from man in Porto Rico. The *Fasciola* from sheep in Porto Rico appears to be a quite distinct species on comparison with the European specimens, but a comparison with American specimens seems to furnish a complete series of gradations between the typical Porto Rican and the European forms. Dr. Stiles noted that cases had been reported from Porto Rico of death from asphyxiation as a result of *Fasciola* attaching in the throat following the eating of raw liver. The prompt production of vomiting will carry out the flukes and save the patient. There is a total of 26 to 28 cases of infection of man with *Fasciola*, most of the cases being discovered on postmortem.

Dr. Garrison presented a report on the terminology of parasitic diseases, and the remainder of the evening was spent in a discussion of his paper.

WHEN the distinguished chairman of your mathematical conference did me the honor to request me to speak to you, he was generous enough, whether wisely or unwisely, to leave the choice of a subject to my discretion, merely stipulating that, whatever the title might be, the address itself should bear upon the professional function of those men and women who are engaged in teaching mathematics in secondary schools. Inexpertness, it has been said, is the curse of the world; and one may, not unnaturally, feel some hesitation in undertaking a task that might seem to resemble the rôle of a physician when, as sometimes happens, he is called upon to treat a patient whose health and medical competence surpass his own. I trust I am not wanting in that natural feeling. In the present instance two considerations have enabled me to overcome it. One of them is that, having had some experience in teaching mathematics in secondary schools, I might, it seemed to me, regard that experience, though it was gained more than a score of years ago, as giving something like a title to be heard in your councils. The other consideration is that, in regard to the teaching of mathematics, whether in secondary schools or in colleges, I have acquired a certain conviction, a pretty firm conviction, which, were it properly presented, you would doubtless be generous enough and perhaps ingenious

¹ *NOTE.* Intended for publication and books, etc., intended for review should be sent to the Editor of SCIENCE, Garrison-on-Hudson, N. Y.

¹ Address given at the meeting of the Michigan School Masters' Club, at Ann Arbor, March 28, 1912.

enough to regard as having some sort of likeness to a message.

My conviction is, that hope of improvement in mathematics teaching, whether in secondary schools or in colleges, lies mainly in the possibility of humanizing it. It is worth while to remember that our pupils are human beings. What it means to be a human being we all of us presumably know pretty well; indeed we know it so well that we are unable to tell it to one another adequately; and, just because we do so well know what it means to be a human being, we are prone to forget it as we forget, except when the wind is blowing, that we are constantly immersed in the earth's atmosphere. To humanize the teaching of mathematics means so to present the subject, so to interpret its ideas and doctrines, that they shall appeal, not merely to the computatory faculty or to the logical faculty but to all the great powers and interests of the human mind. That mathematical ideas and doctrines, whether they be more elementary or more advanced, admit of such a manifold, liberal and stimulating interpretation, and that therefore the teaching of mathematics, whether in secondary schools or in colleges, may become, in the largest and best sense, human, I have no doubt. That mathematical ideas and doctrines do but seldom receive such interpretation and that accordingly the teaching of mathematics is but seldom, in the largest and best sense, human, I believe to be equally certain. That the indicated humanization of mathematical teaching, the bringing of the matter and the spirit of mathematics to bear, not merely upon certain fragmentary faculties of the mind, but upon the whole mind, that this is a great desideration is, I assume, beyond dispute.

How can such humanization be brought about? The answer, I believe, is not far

to seek. I do not mean that the answer is easy to discover or easy to communicate. I mean that the game is near at hand and that it is not difficult to locate it, though it may not be easy to capture it. The difficulty inheres, I believe, in our conception of mathematics itself; not so much in our conception of what mathematics, in a definitional sense, is, for that sense of what mathematics is has become pretty clear in our day, but in our sense or want of sense of what mathematics, whatever it may be, humanly signifies. In order to humanize mathematical teaching it is necessary, and I believe it is sufficient, to come under the control of a right conception of the human significance of mathematics. It is sufficient, I mean to say, and it is necessary, greatly to enlarge, to enrich and to vitalize our sense of what mathematics, regarded as human enterprise, signifies.

What does mathematics, regarded as an enterprise of the human spirit, signify? What is a just and worthy sense of the human significance of mathematics?

To the extent in which any of us really succeeds in answering that question worthily, his teaching will have the human quality, in so far as his teaching is, in point of external circumstance, free to be what it would. I believe it is important to put the question, and it is with the putting of it rather than with the proposing of an answer to it that I am here at the outset mainly concerned. For any one who is really to acquire possession of an answer that is worthy must win the answer for himself. I need not say to you that such an acquisition as a worthy answer to this kind of question does not belong to the category of things that may be lent or borrowed, sold or bought, donated or acquired by gift. No doubt the answers we may severally win will differ as our temperaments differ. Yet the matter is not solely

a matter of temperament. It is much more a matter first of knowledge and then of the evaluation of the knowledge and of its subject. To the winning of a worthy sense of the human significance of mathematics two things are indispensable, knowledge and reflection: knowledge of mathematics and reflection upon it. To the winning of such a sense it is essential to have the kind of knowledge that none but serious students of mathematics can gain. Equally essential is another thing and this thing students of mathematics in our day do not, or do but seldom, gain. I mean the kind of insight and the liberality of view that are to be acquired only by prolonged contemplation of the nature of mathematics and by prolonged reflection upon its relations of contrast and similitude to the other great forms of spiritual activity.

The question, though it is a question about mathematics, is not a mathematical question, it is a philosophical question. And just because it is a philosophical question, mathematicians, despite the fact that one of the indispensable qualifications for considering it is possessed by them alone, have in general ignored it. They have, in general, ignored it, and their ignoring of it may help to explain the curious paradox that whilst the world, whose mathematical knowledge varies from little to less, has always as if instinctively held mathematical science in high esteem, it has at the same time usually regarded mathematicians as eccentric and abnormal, as constituting a class apart, as being something more or something less than human. It may explain, too, I venture to believe it does partly explain, both why it is that in the universities the number of students attracted to advanced lectures in mathematics compared with the numbers drawn to advanced courses in some other great subjects not inherently more attractive, is

so small; and why it is that, among the multitudes who pursue mathematics in the secondary schools, only a few find in the subject anything like delight. For I do not accept the traditional and still current explanation, that the phenomenon is due to a well-nigh universal lack of mathematical faculty. I maintain, on the contrary, that a vast majority of mankind possess mathematical faculty in a very considerable degree. That the average pupil's interest in mathematics is but slight, is a matter of common knowledge. His lack of interest is, in my opinion, due, not to a lack of the appropriate faculty in him, but to the circumstance that he is a human being, whilst mathematics, though it teems with human interest, is not presented to him in its human guise.

If you ask the world—represented, let us say, by the man in the street or in the market place or the field—to tell you its estimate of the human significance of mathematics, the answer of the world will be, that mathematics has given mankind a metrical and computatory art essential to the effective conduct of daily life, that mathematics admits of countless applications in engineering and the natural sciences, and finally that mathematics is a most excellent instrumentality for giving mental discipline. Such will be the answer of the world. The answer is intelligible, it is important, and it is good so far as it goes; but it is far from going far enough and it is not intelligent. That it is far from going far enough will become evident as we proceed. That the answer is not intelligent is evident at once, for the first part of it seems to imply that the rudimentary mathematics of the carpenter and the counting-house is scientific, which it is not; the second part of the answer is but an echo by the many of the voice of the few; and, as to the final part, the world's

conception of intellectual discipline is neither profound nor well informed but is itself in sorry need of discipline.

If, turning from the world to a normal mathematician, you ask him to explain to you the human significance of mathematics, he will repeat to you the answer of the world, of course with far more appreciation than the world has of what the answer means, and he will supplement the world's response by an important addition. He will add, that is, that mathematics is the exact science, the science of exact thought or of rigorous thinking. By this he will not mean what the world would mean if the world employed, as sometimes it does employ, the same form of words. He will mean something very different. Especially if he be, as I suppose him to be, a normal mathematician of the modern critical type, he will mean that mathematics is, in the oft-cited language of Benjamin Peirce, "the science that draws necessary conclusions;" he will mean that, in the felicitous words of William Benjamin Smith, "mathematics is the universal art apodictic;" he will mean that mathematics is, in the nicely technical phrase of Pieri, "a hypothetico-deductive system." If you ask him whether mathematics is the science of rigorous thinking about *all* the things that engage the thought of mankind or only about a few of them, such as numbers, figures, certain operations, and the like, the answer he will give you depends. If he be a normal mathematician of the elder school, he will say that mathematics is the science of rigorous thinking about only a relatively few things and that these are such as you have exemplified. And if now, with a little Socratic persistence, you press him to indicate the human significance of a science of rigorous thinking about only a few of the countless things that engage human thought, his answer will give you

but little beyond a repetition of the above-mentioned answer of the world. But if he be a normal mathematician of the modern critical type, he will say that mathematics is the science of rigorous thinking about all the things that engage human thought, about *all* of them, he will mean, in the sense that thinking, as it approaches perfection, tends to assume certain definite forms, that these forms are the same whatever the subject matter of the thinking may be, and that mathematics is the science of these forms *as forms*. If you respond, as you well may respond, that, in accordance with this ontological conception of mathematics, this science, instead of thinking about *all*, thinks about *none*, of the concrete things of interest to human thought, and that accordingly Mr. Bertrand Russell was right in saying that "mathematics is the science in which one never knows what one is talking about nor whether what one says is true"—if you respond that, from the point of view above assumed, that delicious *mot* of Mr. Russell's must be solemnly held as true, and then if, in accordance with your original purpose, you once more press for an estimation of the human significance of such a science, I fear that the reply, if your interlocutor is a mathematician of the normal type, will contain little that is new beyond the assertion that the science in question is very interesting, where, by interesting, he means, of course, interesting to mathematicians. It is true that Professor Klein has said: "Apart from the fact that pure mathematics can not be supplanted by anything else as a means for developing the purely logical faculties of the mind, there must be considered here as elsewhere the necessity of the presence of a few individuals in each country developed in a far higher degree than the rest, for the purpose of keeping up and gradually raising the *general*

standard. Even a slight raising of the general level can be accomplished only when some few minds have progressed far ahead of the average." Here indeed we have, in these words of Professor Klein, a hint, if only a hint, of something better. But Professor Klein is not a mathematician of the normal type, he is hypernormal. If, in order to indicate the human significance of mathematics regarded as the science of the forms of thought as forms, your normal mathematician were to say that these forms constitute, of themselves, an infinite and everlasting world whose beauty, though it is austere and cold, is pure, and in which is the secret and citadel of whatever order and harmony our concrete universe contains, it would yet be your right and your duty to ask, as the brilliant author of "East London Visions" once asked me, namely, what is the human significance of "this majestic intellectual cosmos of yours, towering up like a million-lustered iceberg into the arctic night," seeing that, among mankind, none is permitted to behold its more resplendent wonders save the mathematician himself? But the normal mathematician will not say what I have just now supposed him to say; he will not say it, because he is, by hypothesis, a normal mathematician, and because, being a normal mathematician, he is exclusively engaged in exploring the iceberg. A farmer was once asked why he raised so many hogs. "In order," he said, "to buy more land." Asked why he desired more land, his answer was, "in order to raise more corn." Being asked to say why he would raise more corn, he replied that he wished to raise more hogs. If you ask the normal mathematician why he explores the iceberg so much, his answer will be, in effect at least, "in order to explore it more." In this exquisite circularity of motive, the farmer and the normal mathema-

tician are well within their rights. They are within their rights just as a musician would be within his rights if he chanced to be so exclusively interested in the work of composition as never to be concerned with having his creations rendered before the public and never to attempt a philosophic estimate of the human worth of music. The distinction involved is not the distinction between human and inhuman, between social and anti-social; it is the distinction between what is human or inhuman, social or anti-social, and what is neither the one nor the other. No one, I believe, may contest the normal mathematician's right as a mathematical student or investigator to be quite indifferent as to the social value or the human worth of his activity. Such activity is to be prized just as we prize any other natural agency or force that, however undesignedly, yet contributes, sooner or later, directly or indirectly, to the weal of mankind. The fact is that, among motives in research, scientific curiosity, which is neither moral nor immoral, is far more common and far more potent than charity or philanthropy or benevolence. But when the mathematician passes from the rôle of student or investigator to the rôle of teacher, that right of indifference ceases, for he has passed to an office whose functions are social and whose obligations are human. It is not his privilege to chill and depress with the encasing fogs of the iceberg. It is his privilege and his duty, in so far as he may, to disclose its "million-lustered" splendors in all their power to quicken and illuminate, to charm and edify, the whole mind.

The conception of mathematics as the science of the forms of thought as forms, the conception of it as the refinement, prolongation and elaboration of pure logic, is, as you are doubtless aware, one of the great outcomes, perhaps I should say it is

the culminating philosophical outcome, of a century's effort to ascertain what mathematics, in its intimate structure, is. This conception of what mathematics is comes to its fullest expression and best defense, as you doubtless know, in such works as Schroeder's "Algebra der Logik," Whitehead's "Universal Algebra," Russell's "Principles of Mathematics," Peano's "Formulario Mathematico," and especially in Whitehead and Russell's monumental "Principia Mathematica." I cite this literature because it tells us what, in a definitional sense, the science in which the normal mathematician is exclusively engaged, is. If we wish to be told what that science humanly signifies, we must look elsewhere; we must look to a mathematician like Plato, for example, or to a philosopher like Poincaré, but especially must we look to our own faculty for discerning those fine connective things—community of aim, interformal analogies, structural similitudes—that bind all the great forms of human activity and aspiration—natural science, theology, philosophy, jurisprudence, religion, art and mathematics—into one grand enterprise of the human spirit.

In the autumn of 1906 there was published in *Poet Lore* a short poem which, though it says nothing explicitly of mathematics, yet admits of an interpretation throwing much light upon the human significance of the science and indicating well, I think, the normal mathematician's place in the world of spiritual interests. The author of the poem is my excellent friend and teacher, Professor William Benjamin Smith, mathematician, philosopher, poet and theologian. I have not asked his permission to interpret the poem as I shall invite you to interpret it. What its original motive was I am not informed—it may have been the exceeding beauty of the ideas expressed in it or the harmonious

mingling of their light with the melody of their song. The title of the poem is "The Merman and the Seraph." As you listen to the reading of it, I shall ask you to regard the merman as representing the normal mathematician and the seraph as representing, let us say, the life of the emotions in their higher reaches and their finer susceptibilities.

I

Deep the sunless seas amid,
Far from Man, from Angel hid,
Where the soundless tides are rolled
Over Ocean's treasure-hold,
With dragon eye and heart of stone,
The ancient Merman mused alone.

II

And aye his arrowed Thought he wings
Straight at the inmost core of things—
As mirrored in his Magic glass
The lightning-footed Ages pass,—
And knows nor joy nor Earth's distress,
But broods on Everlastingness.
"Thoughts that love not, thoughts that hate not,
Thoughts that Age and Change await not,
All unfeeling,
All revealing,
Scorning height's and depth's concealing,
These be mine—and these alone!"—
Saith the Merman's heart of stone.

III

Flashed a radiance far and nigh
As from the vertex of the sky,—
Lo! a Maiden beauty-bright
And mantled with mysterious might
Of every power, below, above,
That weaves resistless spell of Love.

IV

Through the weltering waters cold
Shot the sheen of silken gold;
Quick the frozen Heart below
Kindled in the amber glow;
Trembling Heavenward Nekkan yearned
Rose to where the Glory burned.
"Deeper, bluer than the skies are,
Dreaming meres of morn thine eyes are
All that brightens
Smile or heightens
Charm is thine, all life enlignens,

Thou art all the soul's desire."—
 Sang the Merman's Heart of Fire.
 "Woe thee, Nekkan! Ne'er was given
 Thee to walk the ways of Heaven;
 Vain the vision,
 Fate's derision,
 Thee that raps to realms elysian,
 Fathomless profounds are thine"—
 Quired the answering voice divine.

V

Came an echo from the West,
 Pierced the deep celestial breast;
 Summoned, far the Seraph fled,
 Trailing splendors overhead;
 Broad beneath her flying feet,
 Laughed the silvered ocean-street.

VI

On the Merman's mortal sight
 Instant fell the pall of Night;
 Sunk to the sea's profoundest floor
 He dreams the vanished Vision o'er,
 Hears anew the starry chime,
 Ponders aye Eternal Time.
 "Thoughts that hope not, thoughts that fear not,
 Thoughts that Man and Demon veer not
 Times unending
 Comprehending,
 Space and worlds of worlds transcending,
 These are mine—but these alone!"—
 Sighs the Merman's heart of stone.

I have said that the poem, if it receive the interpretation that I have invited you to give it, throws much light on the human significance of mathematics and indicates well the place of the normal mathematician in the world of spiritual interests. No doubt the place of the merman and the place of the angel are not the same: no doubt the world of whatsoever in thought is passionless, infinite and everlasting, and the world of whatsoever in feeling is high and beauteous and good are distinct worlds, and they are sundered wide in the poem. But, though in the poem they are held widely apart, in the poet they are united. For the song is not the merman's song nor are its words the words of the

seraph. It is the voice of the poet—a voice of man. The merman's world and the world of the seraph are not the same, they are very distinct; in conception they are sundered; they may be sundered in life, but in life it need not be so. The merman indeed is confined to the one world and the seraph to the other, but man, a man unless he be a merman, may inhabit them both. For the angel's denial, the derision of fate, is not spoken of man, it is spoken of the merman; and the merman's sigh is not his own, it is a human sigh—so lonely seems the merman in the depths of his abode.

No, the world of interests of the human spirit is not the merman's world alone nor the seraph's alone. It is not so simple. It is rather a cluster of worlds, of worlds that differ among themselves as differ the lights by which they are characterized. As differ the lights. The human spirit is susceptible of a variety of lights and it lives at once in a corresponding variety of worlds. There is perception's light, commonly identified with solar radiance or with the radiance of sound, for music, too, is, to the spirit, a kind of illumination: perceptual light, in which we behold the colors, forms and harmonies of external nature: a beautiful revelation—a world in which any one might be willing to spend the remainder of his days if he were but permitted to live so long. And there is imagination's light, disclosing a new world filled with wondrous things, things that may or may not resemble the things revealed in perception's light but are never identical with them: light that is not superficial nor constrained to paths that are straight but reveals the interiors of what it illuminates and phases that look away. Again, there is the light of thought, of reason, of logic, the light of analysis, far dimmer than perception's light, dimmer, too, than that of imagination, but far more penetrating and far more

ubiquitous than either of them, disclosing things that curiously match the things that they disclose and countless things besides, namely, the world of ideas and the relations that bind them: a cosmic world, in the center whereof is the home of the merman. There remains to be named a fourth kind of light. I mean the light of emotion, the radiance and glory of things that, save by gleams and intimations, are not revealed in perception or in imagination or in thought: the light of the seraph's world, the world of the good, the true and the beautiful, of the spirit of art, of aspiration and of religion.

Such, in brief, is the cluster of worlds wherein dwell the spiritual interests of the human beings to whom it is our mission to teach mathematics. My thesis is that it is our privilege to show, in the way of our teaching it, that its human significance is not confined to one of the worlds but, like a subtle and ubiquitous ether, penetrates them all. Objectively viewed, conceptually taken, these worlds, unlike the spheres of the geometrician, do not intersect—a thing in one of them is not in another; but the things in one of them and the things in another may own a fine resemblance serving for mutual recall and illustration, effecting transfer of attention—transformation as the mathematicians call it—from world to world; for whilst these worlds of interest, objectively viewed, have naught in common, yet subjectively they are united, united as differing mansions of the house of the human spirit. A relation, for example, between three independent variables exists only in the gray light of thought, only in the world of the merman; the habitation of the geometric locus of the relation is the world of imagination; if a model of the locus be made or a drawing of it, this will be a thing in the world of perception; finally, the wondrous correlation

of the three things, or the spiritual qualities of them—the sensuous beauty of the model or the drawing, the unailing validity of the given relation holding as it does throughout “the cycle of the eternal year,” the immobile presence of the locus or image poised there in eternal calm like a figure of justice—these may serve, in contemplating them, to evoke the radiance of the seraph's world: and thus the circuit and interplay, ranging through the world of imagination and the world of thought from what is sensuous to what is supernal, is complete. It would not have seemed to Plato, as it may seem to us, a far cry from the prayer of a poet to the theorem of Pythagoras, for example, or to that of Archimedes respecting a sphere and its circumscribing cylinder. Yet I venture to say, that calm reflection upon the existence and nature of such a theorem—cloistral contemplation, I mean, of the fact that it is really true, of its serene beauty, of its silent omnipresence throughout the infinite universe of space, of the absolute exactitude and invariance of its truth from everlasting to everlasting—will not fail to yield a sense of reverence and awe akin to the feeling that, for example, pervades this choral prayer by Sophocles:

“Oh! that my lot may lead me in the path of holy innocence of word and deed, the path which august laws ordain, laws that in the highest empyrean had their birth, of which Heaven is the father alone, nor did the race of mortal men beget them, nor shall oblivion put them to sleep. The god is mighty in them and he groweth not old.”

But why should we think it strange that interests, though they seem to cluster about opposite poles, are yet united by a common mood? Of the great world of human interests, mathematics is indeed but a part; but is a central part, and, in a profound

and precious sense, it is "the eternal type of the wondrous whole." For poetry and painting, sculpture and music—art in all its forms—philosophy, theology, religion and science, too, however passionate their life and however tinged or deeply stained by local or temporal circumstance, yet have this in common: they all of them aim at values which transcend the accidents and limitations of every time and place; and so it is that the passionlessness of the merman's thought, the infiniteness of the kind of being he contemplates and the everlastingness of his achievements enter as essential qualities into the ideals that make the glory of the seraph's world. I do not forget, in saying this, that, of all theory, mathematical theory is the most abstract. I do not forget that mathematics therefore lends especial sharpness to the contrast in the Mephistophelian warning:

Gray, my dear friend, is all theory,
Green the golden tree of life.

Yet I know that one who loves not the gray of a naked woodland has much to learn of the esthetic resources of our northern clime. A mathematical doctrine, taken in its purity, is indeed gray. Yet such a doctrine, a world-filling theory woven of gray relationships finer than gossamer but stronger than cables of steel, leaves upon an intersecting plane a tracery surpassing in fineness and beauty the exquisite artistry of frost-work upon a windowpane. Architecture, it has been said, is frozen music. Be it so. Geometry is frozen architecture.

No, the belief that mathematics, because it is abstract, because it is static and cold and gray, is detached from life, is a mistaken belief. Mathematics, even in its purest and most abstract estate, is not detached from life. It is just the ideal handling of the problems of life, as sculpture

may idealize a human figure or as poetry or painting may idealize a figure or a scene. Mathematics is precisely the ideal handling of the problems of life, and the central ideas of the science, the great concepts about which its stately doctrines have been built up, are precisely the chief ideas with which life must always deal and which, as it tumbles and rolls about them through time and space, give it its interests and problems, and its order and rationality. That such is the case a few indications will suffice to show. The mathematical concepts of constant and variable are represented familiarly in life by the notions of fixedness and change. The concept of equation or that of an equational system, imposing restriction upon variability, is matched in life by the concept of natural and spiritual law, giving order to what were else chaotic change and providing partial freedom in lieu of none at all. What is known in mathematics under the name of limit is everywhere present in life in the guise of some ideal, some excellence high-dwelling among the rocks, an "ever flying perfect" as Emerson calls it, unto which we may approximate nearer and nearer, but which we can never quite attain, save in aspiration. The supreme concept of functionality finds its correlate in life in the all-pervasive sense of interdependence and mutual determination among the elements of the world. What is known in mathematics as transformation—that is, lawful transfer of attention, serving to match in orderly fashion the things of one system with those of another—is conceived in life as a process of transmutation by which, in the flux of the world, the content of the present has come out of the past and in its turn, in ceasing to be, gives birth to its successor, as the boy is father to the man and as things, in general, be-

come what they are not. The mathematical concept of invariance and that of infinitude, especially the imposing doctrines that explain their meanings and bear their names—what are they but mathematicizations of that which has ever been the chief of life's hopes and dreams, of that which has ever been the object of its deepest passion and of its dominant enterprise, I mean the finding of worth that abides, the finding of permanence in the midst of change, and the discovery of the presence, in what has seemed to be a finite world, of being that is infinite? It is needless further to multiply examples of a correlation that is so abounding and complete as indeed to suggest a doubt whether it be juster to view mathematics as the abstract idealization of life than to regard life as the concrete realization of mathematics.

Finally, I wish to emphasize the fact that the great concepts out of which the so-called higher mathematical branches have grown—the concepts of variable and constant, of function, class and relation, of transformation, invariance, and group, of finite and infinite, of discreteness, limit, and continuity—I wish, in closing, to emphasize the fact that these great ideas of the higher mathematics, besides penetrating life, as we have seen, in all its complexity and all its dimensions, are omnipresent, from the very beginning, in the *elements* of mathematics as well. The notion of group, for example, finds easy and beautiful illustration, not only among the simpler geometric motions and configurations, but even in the ensemble of the very integers with which we count. The like is true of the distinction of finite and infinite, and of the ideas of transformation, of invariant, and nearly all the rest. Why should the presentation of them have to await the uncertain advent of graduate

years of study? For life already abounds, and the great ideas that give it its interests, order and rationality, that is to say, the focal concepts of the higher mathematics, are everywhere present in the elements of the science as glistening bassets of gold. It is our privilege, in teaching the elements, to avail ourselves of the higher conceptions that are present in them; it is our privilege to have and to give a lively sense of their presence, their human significance, their beauty and their light. I do not advocate the formal presentation, in secondary schools, of the higher conceptions, in the way of printed texts, for the printed text is apt to be arid and the letter killeth. What I wish to recommend is the presentation of them, as opportunity may serve, in Greek fashion, by means of dialectic, face to face, voice answering to voice, animated with the varying moods and motions and accents of life—laughter, if you will, and the lightning of wit to cheer and speed the slower currents of sober thought. Of dialectic excellence, Plato at his best, as in "Phædo" or the "Republic," gives us the ideal model and eternal type. But Plato's ways are frequently circuitous, wearisome and long. They are ill suited to the manners of a direct and undeliberate age; and we must find, each for himself, a shorter course. Somebody imbued with the spirit of the matter, possessed of ample knowledge and having, besides, the requisite skill and verve ought to write a book showing, in so far as the printed page can be made to show, how naturally and swiftly and with what a delightful sense of emancipation and power thought may pass by dialectic paths from the traditional elements of mathematics both to its larger concepts and to a vision of their bearings on the higher interests of life. I need not say that such a handling of ideas implies

much more than a verbal knowledge of their definitions. It implies familiarity with the doctrines that unfold the meanings of the ideas defined. It is evident that, in respect of this matter, the scripture must read: Knowing the doctrine is essential to living the life.

C. J. KEYSER

COLUMBIA UNIVERSITY

BENJAMIN FRANKLIN THOMAS

No more unexpected and startling announcement ever came to the writer than that of the death of Professor Thomas last summer. Only a few weeks before he was apparently in rugged health and as much interested as ever in the various phases of his department of science and its applications. The workers die but the work goes on.

Professor Thomas was born at Palmyra, Ohio, October 14, 1850, and died near his summer home in Maine, July 4, 1911. He received his preparation for college under private tutorage in Fox Lake, Wisconsin, and took the degree of Master of Science at Ripon College in 1874. Then followed one year at the Fort Berthold Indian Reservation in Dakota, two years as instructor at Carlton College in Minnesota and three years as a graduate student at the Massachusetts Institute of Technology and research assistant at the Stevens Institute in Hoboken. At this last institution he earned the degree of Doctor of Philosophy in 1880. The next five years he spent as professor of physics at the University of Missouri. In 1885 he was elected to the same chair in succession to Dr. T. C. Mendenhall at the Ohio State University. To this institution he gave twenty-six years of undivided and efficient service in the cause of education. This term of service covered the critical formative period while the institution was evolving from a small "College of Agriculture and Mechanic Arts" into the great state university of the present. His compelling logic, clear mental grasp of a difficult situation, and his exceptional gift for orderly statement made his services of great value in

faculty meetings, in hearings before legislative committees, and as an expert witness in important cases of litigation.

Professor Thomas was early in foreseeing the immense expansion likely to come in applied electricity, and in 1889 he was instrumental in obtaining from the legislature an appropriation for a building and its equipment to accommodate a course in electrical engineering. This was probably the first college building ever built solely for the purpose of teaching this branch of engineering. His foresight has received abundant justification in a number of graduates in this course who have shed luster on their chosen profession and on their alma mater.

Professor Thomas's especial interest was in the subject of electrical measurements and electrical applications. He was unusually successful in developing the courses in advanced electrical measurements for engineering students; and by careful planning and persistent effort, carried on steadily through many years, he succeeded in getting together a magnificent equipment for this work. At the same time he elaborated a strong course of instruction which matched the fine equipment for effective use. He was a remarkably skilful experimenter in the study of rapidly varying electrical phenomena. His oscillograms of electric discharges and of waves of electric pressure and current are the most beautiful the writer has ever seen.

Professor Thomas's practical work as an electrical expert early led him to a thorough study of the photometry of arc and incandescent lamps, and enabled him to give valuable aid in electric lighting to many great institutions of the state, such as the Ohio Soldiers' and Sailors' Orphans Home, the state house at Columbus and the State Hospitals at Athens, Dayton and Toledo. He was for a number of years director of the Ohio Meteorological Bureau before it was merged into the United States Weather Bureau. He was also the representative for the state in the meetings called by the Bureau of Standards in Washington to confer on the subject of correct weights and measures.

Among the public positions filled by Professor Thomas was that of member of the board of examiners at the International Electrical Exhibition in Philadelphia in 1884 and of the Jury of Awards in the Department of Electricity at the Columbian Exhibition in 1893. At the latter he was placed in charge of a very elaborate test of the life and efficiency of incandescent electric lamps. The results of this prolonged test unfortunately were never published by the government. He was an expert judge of electrical instruments, machinery and processes, and he was in consequence much in demand as a consulting engineer to design the electric plants of large establishments.

As a teacher Professor Thomas excelled in the clearness and precision of his statements. These were matched by the success of his experimental demonstrations. From his students he invariably demanded solid, substantial work; he was impatient with careless or slovenly ways either in the class-room or the laboratory, and constantly held up to his classes high standards of attainment.

The new and substantial physics building at the Ohio State University is a monument to his persistent effort and to his good judgment in planning and working out various details for convenience and efficiency. In the work of his department and all that pertained to it he was indefatigable; to it he gave more than the full measure of time and energy.

Professor Thomas was a genial friend; none more so. The writer was favored with that friendship for many years, and he here gladly gives expression to his deep appreciation of all that this friendship meant to him. Only the bereaved wife, the son and the daughter know what it means to lose a faithful husband and a fond father.

HENRY S. CARHART

ATTENDANCE AT GERMAN UNIVERSITIES

THE *Deutscher Universitäts-Kalender* for the summer semester of 1912, which has just been published, contains a table showing the

enrollment of the twenty-one German universities during the winter semester of 1911-12. The table shows that there were in attendance 57,398 students, as contrasted with 57,200 for the preceding summer semester. This is, however, exclusive of 5,563 auditors, who, if added, would run the grand total to 62,961, as against 61,274 during the summer semester. The University of Berlin continues to lead the list with an enrollment of 9,829 matriculated students, of whom over 5,000 are enrolled in the faculty of philosophy, about 2,000 in the faculty of medicine (including pharmacy and dentistry), 2,412 in law, and 427 in Protestant theology. In addition there were in attendance 776 male auditors and 258 female auditors, bringing the total enrollment of the university during the past winter semester to 10,863, as against 10,720 during the winter semester of 1910-11. The Prussian University of Berlin is followed by the Bavarian University of Munich, which had an enrollment of 8,797 matriculated students and 782 auditors. The Saxon University of Leipzig ranks third with 5,170 matriculated students and 925 auditors. The remaining universities rank in point of attendance as follows: Bonn, 4,279; Breslau, 3,113; Halle, 3,112; Göttingen, 2,637; Freiburg, 2,614; Heidelberg, 2,418; Münster, 2,314; Strassburg, 2,298; Marburg, 2,014; Tübingen, 1,994; Jena, 1,831; Königsberg, 1,694; Kiel, 1,661; Würzburg, 1,583; Giessen, 1,428; Erlangen, 1,261; Greifswald, 1,223; Rostock, 955; the figures in each case being inclusive of auditors. During the winter semester of 1893-94 the universities ranked as follows: (1) Berlin, (2) Munich, (3) Leipzig, (4) Halle, (5) Würzburg, (6) Bonn, (7) Breslau, (8) Tübingen, (9) Erlangen, (10) Freiburg, (11) Heidelberg, (12) Strassburg, (13) Marburg, (14) Göttingen, (15) Greifswald, (16) Königsberg, (17) Jena, (18) Giessen, (19) Kiel, (20) Rostock, and (21) Münster. It will thus be seen that there has been no change in the order of the three largest universities, but that several institutions which were in the lower half of the list eighteen years ago, have grown sufficiently to advance

them into the first division, notably Münster, Strassburg and Göttingen.

Of the 57,398 matriculated students, 2,853 were registered in Protestant theology, 1,770 in Catholic theology, 11,632 in law, 13,870 in medicine, and 27,273 in the faculty of philosophy. In addition there were 3,824 male auditors and 1,739 female auditors. In addition to the female auditors there were 2,796 matriculated women in attendance, as against 2,551 during the summer semester of 1911; 2,126 of these were registered under the faculty of philosophy, 600 in medicine, 65 in law and 5 in theology.

Of the 57,398 matriculated students, 52,435 came from Germany, while 4,417 came from other European countries, 338 from America, 175 from Asia, 28 from Africa and 5 from Australia. The largest delegations from European countries hailed from Russia (2,211), Austria (842), Switzerland (341), Roumania (166), Great Britain and Ireland (160), Bulgaria (153) and Greece (98). Berlin attracts by far the largest number of foreign students, namely, 1,536, being followed by Munich (752), Leipzig (697), Halle (320), Heidelberg (215), Königsberg (203), Göttingen (172) and Breslau (160).

R. TOMBO, JR.

THE MEDICAL SCHOOL OF THE UNIVERSITY OF ILLINOIS

THE University of Illinois undertook some years ago in the city of Chicago an experiment in the work of medical education. As it had received no grant from the legislature for the erection of a plant, it leased the buildings, ground and equipment necessary for the use of a medical school from the College of Physicians and Surgeons in the city of Chicago. The rental paid for this property was very reasonable, not exceeding, in fact, the fixed charges of the plant, counting in the interest on the mortgages and bonds and the requirements of the sinking fund. The school has been conducted for some fifteen years under this general arrangement, with details varied from time to time. During that period the school has been greatly improved, and ranks

to-day among the good American medical schools.

The University of Illinois, however, has never expended upon this school or its management or in rent for the use of the property, a single dollar from the state appropriations. It has been limited to the use of the fees paid by students. The claim may be fairly made that no better school, conducted on the basis of student fees alone, can be found in the country. The time has come, however, when no medical school can be maintained in accordance with modern standards, whose only support is derived from the payment of fees by students. Recognizing this fact, and unwilling to conduct an inferior school, the university has asked the legislature upon three different occasions for funds to put the school upon a proper basis. The legislature granted at one time the sum of \$389,000 for the purpose of providing an adequate plant for the use of the medical school. The governor, however, vetoed this bill. In answer to the last request from the university, the legislature granted (at the 47th Session) for the present biennium, the sum of \$60,000 per annum for the equipment, maintenance and extension of the college of medicine of the University of Illinois. This appropriation was lost by the recent decision of the Supreme Court that it was unconstitutional, owing to the fact that the provision in the bill making this appropriation had been amended in the conference committee without having been printed.

The university now renews its request to the General Assembly for an appropriation for the equipment, maintenance and extension of its work in medicine and public health. The College of Physicians and Surgeons, however, has decided not to renew to the university the lease for the use of its present plant in the city of Chicago when it expires on June 30, 1912.

Owing to the fact that there is no other adequate plant in the city of Chicago which can be obtained for the use of a medical school, at a reasonable rental, the board of trustees of the university have been compelled to announce the closing of the medical

work in Chicago. They have decided to develop the medical work already begun at the site of the university in Urbana-Champaign.

To carry on this enterprise a special building is absolutely necessary, since there is no available space to house such work in the buildings now upon the campus, or in those authorized to be erected by the present legislature.

The trustees of the University of Illinois, therefore, have asked the general assembly to appropriate at its special session the sum of \$250,000 for the development of its work in public health and medicine at Urbana-Champaign. The greater part of this money will be used for the erection, furnishing and equipment of a medical building. It is proposed to organize those fundamental courses in medicine and public health which should be required by all schools of medicine, and which every physician, no matter what method of practise he may adopt, must be presumed to know, such as physiology, bacteriology, histology, anatomy, pathology and sanitation.

SCIENTIFIC NOTES AND NEWS

At the meeting of the National Academy of Sciences, held in Washington on April 18, new members were elected as follows: R. W. Wood, professor of experimental physics at the Johns Hopkins University; Harry Fielding Reid, professor of geological physics at the Johns Hopkins University; David White, geologist, U. S. Geological Survey; Roland Thaxter, professor of cryptogamic botany at Harvard University; Chas. B. Davenport, director of the Station for Experimental Evolution, Cold Spring Harbor, N. Y.; W. M. Wheeler, professor of economic entomology at Harvard University; John J. Abel, professor of pharmacology at the Johns Hopkins University; S. J. Meltzer, head of the department of physiology and pharmacology of the Rockefeller Institute for Medical Research.

THE committee on policy of the American Association for the Advancement of Science held meetings at Washington on April 16 and 17. There were present Mr. Minot, chairman

of the committee; Mr. Pickering, president of the association; Mr. Woodward, treasurer; Mr. Howard, permanent secretary, and Messrs. Cattell, Humphreys and Noyes. Various questions were considered, more especially the division of the association into sections, the relation of the sections to the affiliated societies and the program for the Cleveland meeting.

AMONG the many victims of the terrible disaster to the *Titanic* on April 15, were the following members of the American Association for the Advancement of Science: Mr. Edgar J. Meyer, the well-known mining engineer of New York, who joined the association at the second Baltimore meeting in 1908. Colonel John Jacob Astor who, as is well-known, was greatly interested in mechanical and engineering problems, and who joined at the third New York meeting in 1906. Mr. Frank D. Millet, the well-known artist of Washington, New York and London, who joined at the same meeting as did Colonel Astor. Mr. Millet's interest in science was great and was intensified by his long association with the scientific men in the Cosmos Club of Washington. Dr. Howard, the permanent secretary of the association relates the following anecdote of Mr. Millet: At the time of the meeting of the International Congress of Zoology at Washington in 1907, following the Boston meeting, Dr. Howard was dining one night at the Cosmos Club with Geza Horvath, of the Natural History Museum of Budapest, and G. Severin, of the Natural History Museum of Brussels. As Millet entered the room, he was called over since his knowledge of foreign languages was great and he was much interested in the foreign visitors. He was introduced and at once saluted Horvath in excellent Hungarian; then turning to Severin, instead of speaking to him in French as one naturally would do to a visitor from Brussels, addressed him in Flemish, having, with his artistic eye, noted his apparent descent. Both foreigners were greatly charmed and became at once interested in the man and have always sent greetings to him in their later letters to Dr. Howard.

DR. PAUL G. FREER, director of the United States Government Scientific Bureau in the Philippines and previously professor of chemistry in the University of Michigan, died at Beguio on April 17, at the age of forty-nine years.

THE letters of the late Professor William James are being collected for biographical purposes. Those who have any of his letters can render assistance that will be highly appreciated by addressing Mr. Henry James, Jr., 95 Irving Street, Cambridge, Mass. Casual or brief letters may have an interest or importance not apparent to the person preserving them; and news of the whereabouts of such letters will be gratefully received.

MR. A. D. HALL, F.R.S., has resigned from the directorship of the Rothamsted Experiment Station.

PROFESSOR H. F. NEWALL, F.R.S., has been elected a member of the Athenæum Club for distinguished eminence in science.

PROFESSOR PAUL WALDEN, of Riga, has been elected an honorary member of the Chemical Society, London.

AT the annual meeting of the Harvey Society, held on April 10, the following officers were elected for 1912-13:

President—Frederic S. Lee.

Vice-president—William H. Park.

Treasurer—Edward K. Dunham.

Secretary—Haven Emerson.

Additional Members of the Executive Committee—S. J. Meltzer, Graham Lusk, W. G. McCallum.

THE *Journal* of the American Medical Association states that a dinner was given to Dr. Ludvig Hektoen at the Chicago Club on April 11 by the faculties of Rush Medical College and the College of Physicians and Surgeons and his former students at these institutions, in honor of the twenty-first anniversary of his entrance into the practise of medicine. Dr. Frank Billings presided. An oil-painting of Dr. Hektoen was presented to him by his friends, the presentation speech being made by Dr. E. R. Le Count. Professor E. O. Jordan and Drs. H. Gideon Wells and James B. Herri-
rick responded to toasts.

PROFESSOR GEORGE GRANT MACCUDY, of Yale University, is installing a hall of European prehistoric anthropology for the American Museum of Natural History, New York.

DR. J. N. ROSE, who has recently been appointed research associate in the Department of Botanical Research of the Carnegie Institution, sailed for Europe on April 17, where he goes to investigate cactus collections in the various botanical gardens of England, France, Italy and Germany. He will be away about two months. His European address will be: Royal Botanic Gardens, Kew, London, England.

PROFESSOR G. FREDERICK WRIGHT, professor emeritus of geology at Oberlin College, president of the Ohio State Archeological and Historical Society, is carrying on a systematic investigation of the Ohio mounds. At present the society is erecting two buildings of importance, one at Columbus, costing \$100,000, to serve as a general library and museum, the other at Fremont, costing \$40,000, to hold the library of Americana left by the late President Rutherford B. Hayes. Professor Wright has in press a volume on "The Origin and Antiquity of Man," which will appear in July.

ON March 27 Dr. Samuel W. Williston, professor of paleontology in the University of Chicago, delivered an address to the students of the Kansas State Agricultural College, at Manhattan. Coincidentally this date was the fortieth anniversary of his graduation from the college. On this date also he matriculated his youngest daughter in the domestic science department of the college. On March 29 Professor Williston delivered a lecture on the "Evolution of Early Vertebrates" to a special meeting of the College Science Club.

AT the annual meeting of the Michigan Academy of Science, held at Ann Arbor March 27-29, the principal address was delivered by Professor Albert A. Michelson, of the University of Chicago. The subject of the address, which was illustrated, was "Iridescent Colors in Birds and Insects." Professor E. C. Case, of the University of Michigan, was elected president of the academy.

THE lecture on "North American Deserts" given by Dr. D. T. MacDougal before the Royal Geographical Society of London in December was repeated by him on request before the four branches of the Royal Scottish Geographical Society in Dundee, Aberdeen, Edinburgh and Glasgow during the first week in April.

PROFESSOR FREDERIC S. LEE, of Columbia University, lectured before the International Y. M. C. A. Training School at Springfield, Massachusetts, on April 12, on "Some Aspects of Muscular Action."

DR. FRANK D. KERN, of Purdue University, gave an illustrated lecture on April 15 before the local Academy of Agricultural Science on the "Floral and Scenic Features of Colorado." A number of seasons spent in studying the plant rusts of that state supplied the basis for the lecture.

PROFESSOR FRANCIS E. LLOYD has recently lectured before the botanical seminar of the Johns Hopkins University on some of his recent work on the tannin content of the acorn (*Quercus laurifolia*). Somewhat later he lectured also before the students of the department of biology, Teachers College, Columbia University, on recent advances in the teaching of botany.

UNDER the auspices of the department of geology two lectures by Professor Isaiah Bowman, of Yale University, were on April 4th delivered at the University of Michigan. The subjects of these lectures were: "The Mountains and Deserts of Bolivia" and "Geographical Explorations in the Peruvian Andes."

DR. IRVING A. FIELD, special investigator for the U. S. Bureau of Fisheries, lectured at Trinity College on the evening of April 18, on the subject "Utilization of Hitherto Unused Marine Organisms as Food."

DR. MARIE STOPES has given a course of ten lectures on the general and geological aspects of paleobotany at University College, London. It was the first course on this aspect of the subject to be given in London.

ON the evening of March 29, the Pennsylvania Chapter of the Society of the Sigma Xi was addressed by Professor William J. Gies, College of Physicians and Surgeons, Columbia University, on the subject, "Chemistry in the Service of Biology." Professor Gies reviewed the history of biological chemistry, explained the problems now being attacked by biological chemists and outlined the problems still open for investigation.

AT the Washington birthday celebration of the University of Pennsylvania it was announced that a donation had been received to endow "The Leidy Memorial Lecture in Science" in memory of the late Professor Joseph Leidy.

WE learn from *Nature* that the Essex Field Club has recently appointed a committee for the purpose of raising a small fund to put in order the tombs of John Ray and Benjamin Allen (which stand adjacent to one another in the churchyard at Black Notley, but have been allowed to fall into disrepair), and to erect at Braintree a memorial to Samuel Dale, of that town, to whom no memorial exists. These three naturalists were friends and contemporaries, living at Braintree or in its immediate vicinity in the closing years of the seventeenth century and the opening years of the eighteenth.

DR. EDWARD DIVERS, F.R.S., emeritus professor of chemistry in the University of Tokyo, died on March 8, aged seventy-five years.

DR. A. PACINOTTI, professor of physics at Pisa, has died at the age of seventy-one years.

THE U. S. Civil Service Commission announces an examination on May 8, to fill vacancies as they may occur in the position of scientist in soil survey, at a salary of \$1,600 per annum, in the Department of Agriculture, for duty in the field.

THE Columbia Chapter of the honorary Society of Sigma Xi held its annual initiation and banquet on April 4. At the initiation ceremonies, the 36 new members elected to the society were welcomed by the president of the chapter, Professor George F. Sever.

He explained the origin and purpose of the society, and introduced Professor Henry S. Munroe who spoke on the "Significance of Sigma Xi." At the banquet which followed at the university, representatives were present from the chapters at Cornell, Yale and Pennsylvania.

MR. C. W. LENG has put his valuable collection of "long horned" beetles at the disposal of the American Museum of Natural History for use in filling gaps in its collections. This means a gift of some 870 specimens covering nearly 300 species not hitherto acquired. Mr. John A. Grossbeck, who has been specializing for some time on the Geometridæ, has given to the museum his entire collection of these moths in addition to the series previously donated.

WE learn from *Nature* that the sixty-fifth annual general meeting of the Paleontographical Society was held in the Geological Society's rooms at Burlington House on March 22, Dr. Henry Woodward, F.R.S., president, in the chair. The annual report referred to the completion of the monograph of English Chalk fishes, and of the second volume of that of Pleistocene mammalia. It also acknowledged the help of the Carnegie Trust for the universities of Scotland in providing the plates for another instalment of Dr. Traquair's monograph of Carboniferous palæoniscid fishes. A special effort had been made to complete works in progress before beginning new undertakings. Miss Margaret C. Crosfield, Mr. George Barrow, Mr. H. R. Knipe and Professor W. W. Watts were elected new members of council. Dr. Henry Woodward, Dr. George J. Hinde and Dr. A. Smith Woodward were reelected president, treasurer and secretary respectively.

THE natural history library of the University of Illinois has been enriched by the addition of a set of *Flora Braziliensis*, in forty folio volumes and costing \$1,500. The set is written in Latin and is said to be the fourth obtained by American libraries, others being at Harvard, Columbia and the Shaw Botanical Gardens.

It is stated in *Nature* that the whole of the famous collection formed by the Rev. Canon Norman, F.R.S., consisting of North Atlantic and Arctic invertebrates other than insects, arachnids and myriopods, has now become the property of the Natural History Museum, the fourth and last instalment having been received recently at Cromwell Road. Of Mollusca there were specimens in 7,114 glass-topped boxes, of Crustacea there were 7,376 bottles and tubes containing specimens, and there were, in addition, 5,544 microscopical slides. The Polyzoa were contained in 1,063 glass-topped boxes, while there were 497 spirit specimens and 185 microscopical slides. The "lower invertebrata" were numerously represented in the earlier instalments.

UNIVERSITY AND EDUCATIONAL NEWS

THE University of Chicago has established a system of retiring allowances for professors or their widows. A fund of \$2,500,000 taken from the \$10,000,000 Rockefeller gift of 1910 has been set aside for this purpose. This pension system will grant to men who have attained the rank of assistant professor or higher, and who have reached the age of sixty-five, and have served fifteen years or more in the institution, 40 per cent. of their salary, and an additional 2 per cent. for each year's service over fifteen. The plan also provides that at the age of seventy a man shall be retired unless the board of trustees specially continues his services. The widow of any professor entitled to the retiring allowance will receive one half the amount due him, provided she had been his wife for ten years.

AT Princeton University a fund of \$5,000 has been established by Mr. Albert Plaut, of New York, for the purpose of encouraging the study of chemistry, especially by securing distinguished chemists to address the Chemical Club; and the Louis Clark Vanuxem foundation has been established by a bequest of \$25,000, under the will of Mr. Vanuxem, for the support of a series of lectures at Princeton annually, at least one half of which must be

upon subjects of current scientific interest. It should have been stated in the last issue of *SCIENCE* that the gift of \$300,000 to Princeton University from Mr. W. C. Procter for the establishment of fellowships was part of his gift of \$500,000, the balance having been used for the construction of a memorial dining hall in the Graduate College.

MRS. H. M. BERNARD, of London, has arranged with Professor Kellogg who is at present in London, to establish a small scholarship in the department of entomology at Stanford, to aid an advanced student for two years in an investigation of some problem in insect evolution. The scholarship will yield one hundred dollars a year besides an additional sum to pay all laboratory fees. Mrs. Bernard is the widow of the English biologist Henry M. Bernard, a student of Ernst Haeckel, at Jena, an authority on the corals and an independent investigator of evolution problems. Mrs. Bernard has recently edited and published many of her husband's notes in a book called "Some Neglected Factors in Evolution" (Putnam's). She has already established an evolution scholarship in the University of London, and expects to found others in three or four American universities.

THE library of the department of botany, Brown University, has received a gift of 150 volumes of rare botanical books, valued at \$2,000, in memory of the late Edward P. Taft, class of '54.

GOVERNOR DIX has signed the Harte bill providing for the establishment of a New York State School of Agriculture on Long Island and appropriating \$50,000 for that purpose. He says in a memorandum that plans should be formed and put into effect for the training of qualified agricultural teachers in one or more of the state normal schools and that an effort should also be made toward the introduction in the public high schools of at least the elementary study of agriculture.

PROFESSOR HENRY B. FINE has resigned the deanship of the faculty of Princeton University but continues as dean of the departments

of science and as Dod professor of mathematics. He has been granted a leave of absence for the next academic year which he will spend in Europe. Dr. William F. Magie, Henry professor of physics, has been elected dean of the faculty to succeed Professor Fine.

DR. ALFRED M. TOZZER has been appointed assistant professor of anthropology at Harvard University.

DR. GILBERT N. LEWIS, research professor of chemistry in the Massachusetts Institute of Technology, has been appointed professor of physical chemistry in the University of California, succeeding the late Willard B. Rising. Dr. H. W. Morse, now of Harvard University, becomes lecturer in chemistry. In the same institution Dr. S. J. Holmes, of the University of Wisconsin, has been appointed associate professor of zoology. The last appointment is made to fill the vacancy caused by the removal of Professor H. B. Torrey to Reed College.

DISCUSSION AND CORRESPONDENCE

PHENOTYPES, GENOTYPES AND GENS

WHILE there should be no objection to weekly revisions of the vocabulary of genetics, if any useful purpose is served, some readers of *SCIENCE* may share in the belief that special terms can have little practical value unless they continue to bear the same or closely related meanings. The word phenotype, for example, seems to have been employed by Professor Johannsen as a statistical term, for a purpose essentially different from that illustrated in Dr. Shull's recent paper, in *SCIENCE* of February 2, 1912, p. 182. Dr. Shull assures us of Professor Johannsen's authority for the new version of phenotype, but this does not destroy the historical interest of previous revelations.

To show the distinction that phenotype once conveyed, a free translation of Johannsen's most direct statement may be given:

Thus we recognize that the "type" in the Queletian sense is merely a superficial appearance which may be deceptive; only through further investigation can it be determined whether one or many biologically different types are present.

Therefore it would be proper to designate the statistically prominent type as an apparent type (*Erscheinungstypus*), or, more briefly and directly, a phenotype (*Phänotypus*). Such phenotypes are in themselves measurable realities; something that can be observed as typical; that is, the centers among series of variations, around which the variants are grouped. The word phenotype serves only to make the necessary mental reservation that from the appearance alone no further conclusion can be drawn. A given phenotype may be an expression of biological unity (*Ausdruck einer biologischen Einheit*), but it does not at all need to be. Indeed, this is not true, in a great majority of cases, of the phenotypes found in nature by statistical investigations of variations.¹

Of course it would be presumptuous to assume that any translation would convey the exact meaning of such a passage, but at least it can be seen that phenotype was being used by Johannsen as a concrete collective term, and not merely as an abstract conception, as Shull has supposed:

"Phenotype" and "genotype," when both are rightly used, are contrasted terms, both being abstractions referring to the type to which an individual or group of individuals belongs, and not to the group of individuals belonging to that type. To illustrate the use of "phenotype" in its correct sense, reference may be made to the F_2 of a Mendelian hybrid.²

When the phenotype idea was brought later on into direct contrast with the genotype idea, the two were compared as abstractions, but this conceptual refinement was for purposes of explanation and did not necessarily supplant the more concrete application of phenotype previously made. Shull need not apologize for himself or for Jennings on account of having used phenotype in a concrete sense. It may be that the first use of the term, as restricted to the statistically prominent center of the group, was too narrow for convenience, but any group that has been found to show a statistical unity could be described at least as phenotypic.

¹Johannsen, W., "Elemente der Exakten Erblichkeitslehre," p. 123.

²Shull, G. H., "'Phenotype' and 'Clone,'" SCIENCE, N. S., Vol. XXXV., February 2, 1912, p. 182.

That Johannsen did not contemplate the employment of "genotype" in any such concrete sense as phenotype seems plain from the statement that accompanies his definition:

Very obvious phenotypical differences may be shown where no genotypical difference is present; and there are also cases where with genotypical diversity the phenotypes are equal. Just for this reason it is of the greatest importance to separate clearly the conception phenotype or apparent type (*Erscheinungstypus*) from the conception genotype or germ-type (*Anlagetypus*), as one might say. With this latter conception, to be sure, we shall not be able to work (*nicht operieren können*)—a genotype does not make its appearance in pure form (*tritt eben nicht rein in die Erscheinung*); but the derived concept of genotypical difference will be of use in manifold ways.

Phenotypes, as we learned from the previous quotation, are found in nature, but genotypes are not. To the unregenerate reader Johannsen's genotype appears to be nothing more than an unframed conception of a germinal or genetic constitution, considered as something apart from the external manifestation of the characters. It is an indirect and complicated substitute for the old distinction between latent and patent characters, between transmission and expression.

To replace the word genotype because it was preoccupied in taxonomic biology may not seem so necessary if it be considered merely as the name of an abstract conception with no real existence that needs to be discussed in biological literature. But that geneticists should wish to keep the word in active use as a major term after its previous history has been pointed out is only one more way of showing disregard for the taxonomic framework of biology.

The adjective use of genotype is hardly more fortunate than the substantive application. Why we should say genotypical differences instead of genetic differences or germinal differences is not obvious, but perhaps the longer word means more to geneticists. If the object was to keep closer to the idea of a germinal constitution made up of separate units or gens, the meaning could have been

conveyed more effectively by speaking of *genic* differences than by adding extra syllables. The "type" part of Johannsen's words has served only to confuse the issues, as in the passage where Shull says that phenotypes and genotypes are abstractions relating to types but not to groups. How can there be typical differences, in any biological sense, unless groups are compared? The fact seems to be that Johannsen was not using the word type in accord with biological traditions, but in a loose metaphysical way that renders the terms more abstract instead of more concrete.

There should have been no difficulty in finding suitable names for the two classes of Mendelian hybrids that Shull has pointed out, instead of allowing them to become confused with Johannsen's genotypes and phenotypes. As the so-called genotypes are supposed to have the same gens, they could be described as isogenic hybrids or isogens. Any group treated as having biological unity may be called an isogen. Johannsen approached the idea of biological unity in the passage explaining the use of phenotype, but did not provide a name for such groups except indirectly through the genotype concept.

The hybrids that have different germinal constitutions, and yet look alike, could be described as isophanic hybrids or isophans. They have the same dominant characters, but this does not involve any complete statistical or phenotypic unity. The groups are formed with reference to alternative, Mendelian characters, instead of on the basis of statistical measurements of continuous variations. As Johannsen pointed out, even genotypical unity does not preclude phenotypical differences.

Pluralizing the word *gen* is another difficulty encountered by geneticists. Johannsen used the term mostly in its German plural form, *Gene*. Our writers have added another letter making a double plural, "genes," something like "memorandas."

Johannsen proposed *gen* as a simplification of Darwin's term *pangen*, to avoid the implications of Darwin's theory of pangenesis:

Instead therefore of *pangen* (*das Pangen*) and

pangens (*die Pangene*), we shall simply say *gen* (*das Gen*) and *gens* (*die Gene*).

Along with this word *gen*, to represent an invisible rudiment or transmitted germ of a character, it will be useful to have a corresponding term, *phan*, to represent an external manifestation or expression of a character. To be able to refer to the external expression or phanic relations of characters is quite as important as to discuss them from the standpoint of theories of transmission. From these two roots it will be easy to develop a simple and appropriate terminology for many of the facts of heredity.

WASHINGTON, D. C.,
February 24, 1912

CROSS CUTTING AND RETROGRADING OF STREAM-BEDS

IN the October (1911) number of the *American Journal of Science*, I read with interest an article by Mr. John Lyon Rich on "Recent Stream Trenching in the Semi-arid Portion of Southwestern New Mexico, a Result of Removal of Vegetation Cover," on which I have ever since intended making brief comment, because it seemed to me Mr. Rich presented only one phase of the subject. While the stated factor, "removal of vegetation cover," may in some localities, accelerate the retrograding (trenching) of stream-beds, it is not, in my opinion, the cause of retrograding. I noted the same characteristics (and others probably also noted) years ago in places where there were no cattle and never had been any.

The "trenching," Mr. Rich says, "is still in progress," which is true, for it has always been and always will be, in progress, cattle or no cattle, vegetation or no vegetation, not only in semi-arid regions but everywhere. There are differences in degree and rate—that is all—and in arid regions the rate is conspicuous.

There are two forces at work wherever water runs or ice flows, which, so far as I know, have not been sufficiently defined up to the present. They are *cross-cutting* and *retro-*

grading of stream-beds. They are close companions and they are among the chief causes of degradation in any region, being more noticeable in mountainous semi-arid regions because inequalities of stream flow are greater in such regions.

Every water course (or glacier course) is subject to cross-cutting, on a greater or smaller scale according to conditions. In semi-arid lands it is often violent.

Take a stream flowing in a semi-arid region over the surface of a sedimentary deposit of say 20 feet in depth. This stream bed terminates in some other stream bed which may be dry most of the time, the water of the first evaporating or seeping away before the junction is reached. For some reason this master-stream corrodes its bed more rapidly than the tributary—by sudden flood, perhaps, in which the tributary does not share. The tributary stream bed is cut away at the junction, leaving it high above the bed of the master-stream—the water, if there is any at this point, cascades. The tributary enters by what has been termed a hanging-valley. The process of retrograding then begins in the tributary stream-bed. It is a process of corrosion by undercutting. It may be slow or fast, depending on many conditions. In arid and semi-arid regions, banks of dry earth often remain vertical for years. This is partly because the surface behind the wall (as pointed out by Stanton in his investigation of the landslides on the Canadian Pacific Railway) becomes impervious to water and, like a roof, prevents the earth mass from becoming saturated. Even when chunks of this earth fall beside a stream they do not readily disintegrate unless completely submerged, because the clay forms on their surface an impervious coating. I have seen earth-cliffs 30 to 40 feet high with all the characteristics of a rock-cliff erosion. The run-off is quick. Steady rains are infrequent. The earth mass can not become saturated. But given an abnormally steady and long-continued rainfall, in combination with a "cloud-burst," at the headwaters, and all is changed with startling rapidity. It is dramatic. The tributary

flood undercuts its precipice steadily and mass upon mass of the earth drops into the flood to dissolve. The precipice travels up stream.

The tributary stream-bed is immediately placed on a par with its master. When the storm is over the precipice of earth is found at all is found miles towards headwaters. The former stream instead of flowing on the surface amidst verdure and willows and cottonwoods, now glides at the bottom of a desolate and barren earth canyon.

In the retrograding it has cross-cut the mouths of other stream-beds, where in time, the operation described is repeated over and over, as the country is gradually lowered by these forces.

There have been many excellent examples of cross-cutting and of violent retrograding, two of which I may mention. In the 60's of the last century one occurred at the little Mormon settlement of Santa Clara in south Utah. In a single night the stream was metamorphosed. At Kanab, south Utah, a similar example took place about 1900. In an astonishingly brief time the Kanab creek meandering amongst willows and vegetation was transformed into a waste for miles of its course. The channels through which the Colorado River broke into the Imperial Valley exhibited retrograding in its violent form and excellent photographs were made at the time.

In the Mukuntoweap Valley in southern Utah cross cutting and retrograding in rock may be studied. Some small valleys that were cross-cut ages ago remain almost unaltered. They hang 1,000 feet above the master-stream. The explanation seems to be that during the Glacial Epoch the high plateaus at the head waters of the Virgin river were heavily piled with snow and ice which, melting in the summers, carried on rapidly the work of corrosion in the main streams which had sources in the very high lands, while the shorter stream-beds with lower sources were even then arid and were left behind, having no power of retrograding to keep level with master streams. In other words the corrosion of the master-streams ran away from the erosion of the drier valleys, leaving the latter hanging

in the air. The process is the same as when earth is concerned.

REPORTED DISCOVERY OF RADIUM IN NORTHERN
ARKANSAS

In this day, new results of scientific work make such rapid appearance that the public in general are very credulous about reported discoveries however unreasonable they may appear, and even scientists are cautious about expressing adverse opinions concerning such, without having carefully investigated them. Apropos of this, a short article that some weeks ago appeared in a St. Louis paper, reporting an alleged discovery of radium in northern Arkansas and naming the writer as authority for its existence, has been somewhat widely copied by the press, and has brought numerous letters to the writer from different parts of the country from New York to California. Among these have been letters from scientists and those engaged in commercial work. The foundation for the report is as follows:

In the latter part of February there came to the writer's office, then at the University of Arkansas, a Mr. Leib, of Bentonville, that state, who brought a cigar box of earthy material which he said came from a cave near his home. It was just such material as might come from any limestone cave. With the box was a photograph which Mr. Leib said had been made by exposing the box containing the material before a camera, for several hours, in an absolutely dark room. The picture was of about the distinctness of an ordinary X-ray photograph. It plainly showed the box, the string about it and the knots in the string.

Mr. Leib was told by both Professor A. A. Steel, of the University of Arkansas, and myself that while the photograph was interesting, careful investigation was necessary before it could be stated that the substance contains any radium or other radio-active material. For this purpose he was advised to

send some of it to Professor B. B. Boltwood, of Yale University.

Such is the basis of a newspaper story that seems to have attracted a good deal of attention.

THE AMERICAN ASSOCIATION FOR THE ADVANCE-
MENT OF SCIENCE

TO THE EDITOR OF SCIENCE: It is generally agreed that the recent Washington meeting of the American Association for the Advancement of Science and its affiliated societies was one of the most enjoyable, helpful and inspiring meetings ever held in this country. The attendance was large, the programs well filled, the discussions earnest and the efforts of the local committees fully successful in providing ample means for social intercourse without too much distraction from the work of the meeting.

Nevertheless, that meeting probably marks the parting of the ways, and it behooves all of us who have been and still are loyal to the American Association for the Advancement of Science to give earnest consideration to the question of the future policy of that union of scientific workers which has in the past done so much to deserve its title.

Two of the fundamental principles of the association are: first, by means of migratory meetings to arouse interest in scientific matters in different sections of the country; second, to bring together workers in all branches of science, for mutual acquaintance and for the development of broader view-points than is possible from too close absorption in one's own special line.

These ideals could be and have been well realized in the past when the average attendance on such meetings was not too large for the hotel accommodations of most of our cities and when it was usually possible to have meetings of various sections in one building, thus enabling closely related sections to meet in adjacent rooms.

But that day has passed. Organization among scientific workers has increased at a tremendous pace during the past few years, largely through the energy of the officers of the organizations of special branches of science. The growth from two thousand to almost six thousand in the membership of the American Chemical Society within the past four years is only typical of the relative activity in other societies.

With such an increase in organization membership it has now become a physical impossibility to longer realize the old ideals of the American Association for the Advancement of Science, and so we hear more and more of withdrawal movements. The example of the zoologists, naturalists and anatomists, during the last convocation week is going to be more and more followed by other societies.

Does this mean the dismemberment of the American Association for the Advancement of Science, the giving up of the opportunity to come in touch with fellow workers in allied sciences, the loss of a national association of organized science? Truly this would be a calamity.

Can such a calamity be avoided?

In the hope of at least provoking discussion, the following suggestions are submitted, in full realization of their imperfections, but nevertheless, as based upon an honest effort to look the situation squarely in the face.

First. Let the American Association for the Advancement of Science lend all of its aid and sympathy to the development of the affiliated societies.

Second. Let the American Association for the Advancement of Science give up its present annual meetings and instead hold triennial or quadrennial meetings.

Third. Let the affiliated societies in turn give up their regular meetings at the time of the American Association for the Advancement of Science meetings and lend all of their influence towards making these meetings great national gatherings of scientists.

Fourth. Let the migratory meetings of the affiliated societies serve the purpose of arousing local public interest in scientific work.

Fifth. Let the meetings of the American Association for the Advancement of Science be held in the national capital, at a time when Congress is not in session and hotel accommodations consequently ample.

If such a policy could be agreed upon by all, the American Association for the Advancement of Science could well afford to give up its charge of an initiation fee from all who are members of affiliated societies. Further, in view of the decreased administrative expense and largely increased membership the present annual dues might possibly be still further reduced.

Such truly national gatherings of scientific workers would be inspiring to all of us, and would make a national impress, as the best conditions would there prevail for the formulation of scientific policies of nation-wide importance.

To carry out the above plan no very great practical difficulties would have to be overcome. The changes are not radical, but evolutionary in character. It is hoped that the suggestions may be of some service.

CHAS. H. HERTY

UNIVERSITY OF NORTH CAROLINA

SCIENTIFIC BOOKS

Bacteria in Relation to Plant Diseases. By ERWIN F. SMITH, in charge of laboratory of plant pathology, Bureau of Plant Industry, U. S. Department of Agriculture. Volume II., History, General Considerations, Vascular Diseases, Washington, D. C. Published by the Carnegie Institution of Washington. 1911. Pp. viii + 368. Quarto. Publication No. 27, Vol. two.

Somewhat more than six years ago the writer of this notice had the pleasure of publishing a note (SCIENCE, Nov. 24, 1905) in regard to the first volume of this work, and there expressed the hope that the publication of the second volume would "not be long delayed." But good and sufficient reasons for the delay are given in the introduction to this volume, where we are told that it is "based in great part on data obtained as the result of a

multitude of experiments made by the writer and his assistants" and that "it has often happened that the ink on some chapters would scarcely be dry before the results obtained from new experiments would require some part of it to be rewritten." We are further told that in this way some chapters were "rewritten a dozen times, in whole or great part." These quotations will serve also to give some idea of the method of science, and of the infinite pains which must be taken before final results are attained.

As indicated by the title of this volume, it deals with the history of the subject, that is, with the successive investigations of workers in this field of science. Some of the pronouncements of the earlier pathologists now make "mighty interesting reading," as shown by the quotations which are liberally given on pages 9 to 20. Then follow nearly two hundred pages of "general considerations" in which are discussed such questions as "the supposed normal occurrence of bacteria in plants" (which is decided in the negative); "bacteria on the surface of plants"; "parasitism"; "inception and progress of the disease"; "reaction of the plant"; "symbiosis," etc. The remainder of the book (about 150 pages) is devoted to "Vascular Diseases," that is, the diseases which have to do with the vessels of plants.

Three vascular diseases are fully discussed, namely, the "Wilt of Cucurbits," the "Black Rot of Cruciferous Plants" and the "Yellow Disease of Hyacinths." These are severally due to the invasion of the tissues by *Bacillus tracheiphilus* Smith, *Bacterium campestre* (Pammel) Smith, and *Bacterium hyacinthi* Wakker. As one reads the pages of descriptions he is impressed with the thoroughness with which the work upon which they are based was done. At every step one sees the results of the most painstaking investigation, much of which extended through many years. And with it there grows the feeling that here at last we have contributions to plant pathology that rest upon solid foundations and from which guesses and inferences have been wholly omitted.

In the introduction (page 4) we are given a convenient grouping of the diseases of plants due to bacteria, viz.: (1) The vascular diseases, (2) the parenchyma diseases without hyperplasia and (3) cankers, tubercles and tumors in which there is a more or less distinct hyperplasia. It will appear from this that the author has treated but one type or group of diseases, and from this we may infer that this volume is to be followed by one or more others, although no hint is given us by the author as to his intentions. It is to be hoped that Volume III. will appear in due time and that if this be not enough still others may follow. We can not help wishing that the plant diseases due to the fungi might find an investigator who would do for them what Dr. Smith is doing for those due to bacteria.

CHARLES E. BESSEY

THE UNIVERSITY OF NEBRASKA

Corrosion of Iron and Steel. By J. NEWTON FRIEND, Ph.D. Longmans Green & Co. 1911. Pp. 300; 62 figures.

Of the many references to the literature of the subject cited by the author, none is more interesting than the following from Pliny written some 2,000 years ago. In his "Natural History" Pliny writes "there is a kind of hallowing iron within the city called Zeugma, seated upon the Euphrates, where-with King Alexander the Great some time bound and strengthened the bridge over the river there; the links whereof, as many as have been repaired and made new since, do gather rust, whereas the rest of the first making be all free therefrom." Evidently at this very early date the observation had been made, not only that iron rusts, but that different pieces may rust at different rates. The general subject has received so much attention from men in widely differing fields, and their publications have appeared in so great a number of places, that there existed a need for a work which would thoroughly digest this literature and gather together that portion which seemed sufficiently reliable to be of service to the investigators of the present. This task, which has not been an easy one, Dr.

Friend has accomplished in a thoroughly satisfactory way in the present volume.

The action of air and water and also steam upon iron is discussed at length, together with the various theories which have been advanced to explain corrosion. The author's experiments to prove that a trace of carbonic acid, however minute, is essential in order that rusting will take place, are of but academic interest, since such conditions can never be duplicated except with the refinements of a laboratory; and his conclusion that the electrolytic theory of iron is untenable is not warranted. In fact, the so-called acid theory which the author vigorously defends is none other than the electrolytic theory, where the assumption is made that the hydrogen ion concentration in pure water is not great enough to produce a speed of reaction sufficiently high to make the rusting of iron at low temperatures obvious; while by the introduction of carbonic acid the concentration of the hydrogen ions is increased to such a point that iron will pass into solution rapidly enough to appear as rust. The book in many places suffers somewhat by the author's unwillingness to make use of the conceptions introduced by the electrolytic theory which, were they used, would simplify the treatment.

The chapters on the factors influencing the rate of corrosion exposed to natural forces, the action of acids and single salts and other electrolytes upon iron are most complete and give the reader a clear idea of the existing knowledge of this phase of the subject. Chapter XII. is devoted to the passive state of iron, and while it seems to contain all that we know upon the subject it emphasizes the fact that our present knowledge is far from giving us a satisfactory explanation for this peculiar phenomenon. The later chapters deal comprehensively with the influence of chemical composition upon the durability of iron, electrical and galvanic action, and the relative rate of corrosion of iron and steel.

It is a matter of regret that the author has been misled, as have also the reviewer and others, by giving credence to statements and data supplied by the American Rolling Mill

Co., of Middletown, Ohio, which he publishes on pages 114, 250, 276 and 251, regarding the purity of this firm's products. For example, the material said to have the analysis published on page 114, as containing 99.954 per cent. iron, and which on page 276 is proposed as a standard for *pure iron* on which to base a corrosion factor, was later found by the author himself, much to his surprise, to contain .172 per cent. copper.

The book constitutes a distinct and valuable contribution to the literature on the subject of corrosion, and will prove of interest to the general reader as well as of great service to those particularly interested in this field.

WILLIAM H. WALKER

Principles of Electrical Engineering. By HAROLD PENDER, Professor of Theoretical and Applied Electricity in the Massachusetts Institute of Technology. New York, McGraw-Hill Book Company. 1911. Pp. xviii + 438.

Convinced that the principles of electrical engineering are the principles of physics—a fact too frequently overlooked—and recognizing that a clear conception of these principles is essential for a proper understanding of the complicated reactions that take place in electric machinery and transmission circuits, the author of this book in an admirable manner deals successively with the more important phenomena of electricity and magnetism, continuous and alternating currents. On the whole the treatment is satisfying and thorough. The mathematical discussions are adequate but, being merely a means to an end, are not too extensive. Descriptions of machinery and apparatus—even of the transformer—are entirely omitted, the book having the same relation to electrical engineering as a first-class treatise on mechanics has to mechanical engineering. There has long been a demand for a comprehensive and thorough treatise of this kind. It has been customary either to shirk the matter and use descriptive texts, or to use separate texts, on the elements of electricity and magnetism, electrostatics, alternating currents, etc.

Technical schools should make every endeavor to develop men who are capable of advancing the art and who are not mere followers of "best practise," an end that may be secured by the more general use of books of this type. The reviewer agrees thoroughly with the author's point of view and in general with his methods; minor criticisms seem unnecessary. The lack of reference to the work of others is noticed. The abbreviation of "logarithm" to \ln , in the same font as is used for expressing quantities, seems undesirable; thus, $\ln i$ is not recognized at once as the familiar $\log i$. Some statements in regard to units might well be qualified by the insertion of "sometimes used" or of some similar phrase; since, for example, no electrical congress has recommended the "gilbert" or the "abvolt," objection may be taken to the statements that the C.G.S. unit of magnetic potential difference is the "gilbert" (p. 92) and the C.G.S. unit of electric potential difference is the "abvolt." In general, however, the phraseology is precise.

FREDERICK BEDELL

Electro-Analysis. By EDGAR F. SMITH, Professor of Chemistry and Provost, University of Pennsylvania. Fifth edition. Philadelphia, P. Blakiston's Son & Co. 1911. 12mo. 332 pages, 46 illustrations, flexible leather binding. Price ?

The revised and enlarged edition of this attractive and useful book contains, as new material, the essentials of all that has appeared upon electro-analysis during the past four years. The author particularly emphasizes his continued success in using the mercury cup and his conviction of its wide utility in electrolytic analysis. To those unfamiliar with the previous editions it may be said that the work contains practically everything of value extant in electro-analysis, presented in most attractive and available form, and that possibly half of the whole subject matter is the direct work of Dr. Smith and his students and assistants. It is quite pertinent to call attention to the fact that many of the methods of

exact quantitative separation and precipitation used in electro-analysis are borrowed from and constitute modifications of industrially applied processes; this is especially true of the mercury cathode methods; reciprocally it is even still more evident that many valuable industrial processes have evolved from the laboratory investigations and the exact manipulations of electro-analysis, and yet more are waiting to be developed. This reciprocal excitation of laboratory and works is a particularly gratifying object lesson in modern scientific and industrial interdependence. We therefore recommend the book most heartily, not only to chemical analysts, but just as strongly to technical electrochemists studying the problems of electrochemistry, both in the research laboratory and in the works.

JOSEPH W. RICHARDS

*THE HABITS OF FLIES OF THE GENUS
CORDYLOBIA, PARASITIC ON MAN
IN AFRICA*

In Africa the larvæ of certain flies (*Cordylobia*) of the family Muscidae are parasitic under the skin of man and other warm-blooded animals in the same manner as are the larvæ of many of the flies usually grouped together as Eristidae. Until recently the manner in which *Cordylobia* infected its host was unknown. Independent results have now thrown light on this question.

Monsieur E. Roubaud, in the *Comptes Rendus Hebdomadaires des Séances de l'Académie des Sciences* of the 23d of October, 1911, presents the results of his studies of the "Ver du Cayor," *Cordylobia anthropophaga* Blanchard. The larva is found under the skin of man and domestic animals. In the Eristidae, with the forms found in tumors under the skin, two distinct modes of infection of the host are known. In both cases the eggs of the fly are laid upon the host. In one case the newly hatched larvæ penetrate at once to their proper habitat, but in the other the eggs are swallowed by the host and the newly hatched larvæ bury themselves in the tissues of the oesophagus and only reach the surface after protracted wanderings within the body of

their host. With these facts in mind M. Roubaud experimented upon *Cordylobia*. He found that eggs placed directly upon the skin do not result in the infection of the animals. In the same way his experiments indicated that where eggs were swallowed by animals no infection followed. His experiments with a third method proved successful. Fifteen small larvæ were taken immediately upon the hatching of the eggs and were placed upon a light layer of sand in a large vessel. A guinea pig was shut up in the vessel for twenty hours and then taken out and placed in a wire cage. The result was that three days afterwards six tumors were found on the under side of the body, upon the muzzle and near the anus, each one containing a rapidly developing larva. His experiments indicate, therefore, that infestation is accomplished exclusively by the direct and active penetration of young larvæ hatched elsewhere. He followed day by day the evolution of the larva and describes the successive stages, which occupy only a week. He believes that Europeans are only accidental hosts of this parasite, but that with the natives who sleep on the ground the infection is naturally much more easy. The investigations were made in the laboratory at Bamako.

Of equal interest are the observations of Herbert von Pelser-Berensberg ("Societas entomologica," Vol. 26, p. 34, July 29, 1911) on *Cordylobia rodhaini* Gedoelst. It had been supposed that uncleanly habits led to infection, but it was found that those persons who bathed most frequently were most subject to infection and the inference was that the eggs were laid upon the exposed body. Keeping eggs under a watch-glass bound to his arm, von Pelser-Berensberg found that the newly hatched larvæ, while they gnawed the skin, did not succeed in penetrating. Later he solved the problem by direct observation. While bathing he noticed that certain flies were attracted to the clothing which he had spread out on bushes, in the sun, to dry off the perspiration. He found that these flies were *Cordylobia* and that they had glued about twenty eggs to his underclothing. As an experiment he continued to wear the clothing.

Examination at the end of the first day showed that the eggs were intact, but on the second day they had hatched. Search with a lens upon the skin revealed some minute red spots and beneath these were the young larvæ, about .5 mm. long.

FREDERICK KNAB

THE NATIONAL ACADEMY OF SCIENCES

THE scientific program of the National Academy of Sciences, which met at Washington on April 16, 17 and 18, was as follows:

George E. Hale: "The New Tower Telescope of the Mount Wilson Solar Observatory."

W. W. Campbell: "Radial Velocities of 213 Brighter Class A Stars." "Radial Velocities of 190 Brighter Class F Stars." "Some Characteristics of Stellar Motions."

W. J. Humphreys (introduced by Cleveland Abbe): "Holes in the Air."

R. A. Harper: "The Organization of the Cell Colony in *Pediastrum*." (By title.)

D. H. Campbell: "On the Morphology and Systematic Position of *Calycularia radiolosa* (Sande Lac) Stephens." (By title.)

William Trelease: "A Revision of *Phoradendron*."

H. F. Osborn: "Biological Foundation of Bergson's 'Creative Evolution.'" (By title.)

E. S. Morse: "Biographical Memoir of C. O. Whitman." (By title.)

G. L. Goodale: "Biographical Memoir of Alexander Agassiz." (By title.)

By invitation of the Council—

Harvey Cushing: "Some Observations on the Functions of the Pituitary Body."

Jacques Loeb: "The Activation of the Animal Egg from the Physico-chemical Standpoint." (By title.)

J. A. Holmes: "The National Phases of the Mining Industry."

C. G. Abbot: "The Solar Radiation."

ANNUAL MEETING OF THE AMERICAN FEDERATION OF TEACHERS OF THE MATHEMATICAL AND THE NATURAL SCIENCES

THE American Federation of Teachers of the Mathematical and the Natural Sciences held its annual meeting at the New Willard Hotel in Washington on December 27.

The associations composing the federation reported concerning their activities during the past year, and the reports of committees were considered as follows:

Action on the recommendations in the report of the committee on college entrance requirements was postponed for one year, with the understanding that the various associations were to take action on it in the meantime, and were to report their decisions to the federation.

The national geometry committee report was approved as a report of progress. The chairman, Dr. Slaughter, reported that a preliminary report would soon be distributed to all members of the federation who were engaged in mathematics teaching, as well as to such other teachers as were interested. An edition of 5,000 copies will be published, the expense being borne by the National Educational Association.

The amendments reorganizing the council by limiting the representation of each association to one member were adopted, as follows:

Section 6. Each association shall have one delegate on the federation council, this delegate to cast one vote for every fifty members of the association he represents, but to have at least one vote. The delegate may be chosen in any way decided upon by his association, shall hold office for three years, or until the appointment of his successor, and shall be eligible for reelection. In case of a vacancy by death or resignation, the association in question must at once appoint a successor.

Section 7. The duty of a delegate shall be to keep the secretary of the federation informed as to the activities of his association, and to represent the interests of his association at every meeting of the council. If for any reason he can not attend a meeting, he shall be responsible for being represented by a properly accredited proxy.

The associations have been asked to appoint these representatives at once, and it is hoped that the new council will soon be in full working order.

The treasurer reported as follows:

EXPENDITURES

Stationery and stamps	\$ 8.50
Printing and mailing	70.52
National Geometry Committee	100.00
	<hr/>
	\$179.02
Balance	85.78
	<hr/>
	\$264.80

RECEIPTS

Balance from 1910	\$ 85.60
Dues from 12 associations	179.20
	<hr/>
	\$264.80

One association, the Association of Biology Teachers of New York, has resigned from the federation, and two associations with an approximate membership of 150 have not yet paid their dues for the year.

A committee of teachers of physics, J. A. Randall, Pratt Institute, Brooklyn, chairman; W. R. Pyle, Morris High School, New York City; W. A. Hedrick, McKinley Manual Training School, Washington, D. C.; G. A. Works, Madison, Wisconsin; P. B. Woodworth, Lewis Institute, Chicago, has been appointed "to coordinate new apparatus and new teaching content with the present secondary school physics course."

Mr. Randall is chairman of a similar committee of the New York State Science Teachers' Association, and committees to cooperate in this work have already been appointed by the Physics Club of New York and the New Jersey State Science Teachers' Association. It is hoped that the National Educational Association will decide, at next summer's meeting, to be a partner in this undertaking, as it has been in the work of the National Geometry Committee.

The plan of work for the committee is to have each member act as chairman of a local committee, which shall investigate conditions in its territory, collecting data as to new apparatus and improvements in courses to be submitted to the general committee, and giving to the instrument makers plans for whatever apparatus seems worth while. The general committee will probably form a new definition of the "physics unit" to correspond with what they find to be the most improved usage in the subject, and will perfect machinery by which every physics teacher in the country can secure the most improved forms of equipment.

On Thursday morning, at a joint session with Section L of the American Association for the Advancement of Science, the members of the council listened to addresses by Professor C. W. Moore, of Harvard; Professor A. L. Jones, of Columbia, and Dean J. R. Angell, of Chicago University, on the new systems of admission to these colleges.

EUGENE R. SMITH,
Secretary

POLYTECHNIC PREPARATORY SCHOOL,
BROOKLYN

ANTHROPOLOGY AT THE WASHINGTON MEETING FOR 1911

THE annual meeting of the American Anthropological Association was held in the United States National Museum, Washington, D. C., December 27-30, 1911, in affiliation with Section H of the American Association for the Advancement of Science and the American Folk-Lore Society. The attendance was good and the program exceptionally long and interesting. The most important features were the two symposia: (1) "The Problems of the Unity or Plurality and the Probable Place of Origin of the American Aborigines," discussed by J. W. Fewkes, A. Hrdlička, W. H. Dall, J. W. Gidley, A. H. Clark, W. H. Holmes, Alice C. Fletcher, Walter Hough, Stansbury Hagar, A. F. Chamberlain and R. B. Dixon; and (2) "Culture and Environment," discussed by J. W. Fewkes, Clark Wissler, Edward Sapir and Robert H. Lowie. The first of these two discussions is printed in full in the January-March issue of the *Anthropologist*, and the second will appear in the April-June issue. Dr. J. Walter Fewkes presided at the six sessions in charge of the American Anthropological Association; also at the single session of the American Folk-Lore Society, in the absence of Professor Henry M. Belden, president of that society. Professor George T. Ladd, vice-president of Section H, was chairman of the single session in charge of the section. The social functions to which members of the affiliated societies were invited included: a reception by Dr. and Mrs. Robert S. Woodward at the Carnegie Institution, a reception at the New National Museum, and the opening of the Corcoran Gallery of Art.

SECTION H

Officers for the Washington meeting were nominated as follows: member of the council, Dr. Ales Hrdlička; member of the general committee, Dr. Charles Peabody. Sectional offices were filled by the nomination and election by the general committee, of Dr. J. Walter Fewkes, Bureau of American Ethnology, as vice-president for the ensuing year; Dr. Alfred M. Tozzer, member of the sectional committee to serve four years (to fill a vacancy), and Dr. Pliny E. Goddard, member of the sectional committee to serve five years.

President Fewkes opened the first public session of the joint meeting with the following remarks:

Ladies and Gentlemen, Members of the American Anthropological Association:

A year has passed since the last meeting of the association and we have now again gathered together, bringing from field and laboratory new material to lay before our fellow workers for their critical examination. It is eminently fitting that we should hold our service in this beautiful building erected by the nation to contain the precious collections gathered from the uttermost parts of the earth as well as our own country. Part of these collections illustrate the physical and cultural history of man, the sciences we cultivate. Our place of meeting should stimulate us with a new enthusiasm and a high ideal of research, and the time of year a new sense of the service to humanity it requires. Although our science has a very practical side, its strength lies primarily in the study of truth for its own sake and thereby the elevation of human character. With your assistance it shall be our effort to eliminate, as far as possible, all personal feeling in our discussions and keep continually in mind the noble ideal that all our work is a service to science.

It has seemed desirable to group our communications in such a way that discussions of methods and principles would be a prominent feature, and it is earnestly hoped that these discussions may be untrammelled by personal feeling, critical when necessary, but always on the highest possible plane. It is evident to all that with so many speakers, all of whom we desire to hear, it may be necessary sometimes for a speaker to curtail his remarks to conform to the time allowed by the committee. Although in such condensation he may feel that he can not do himself full justice, it is to be hoped that he will make the sacrifice for the sake of others who follow.

ADDRESSES AND PAPERS

The address of retiring Vice-president Roland B. Dixon of Section H on "The Independence of the Culture of the American Indian" is printed in *SCIENCE* of January 12, 1912.

In the absence of President Henry M. Belden, of the American Folk-Lore Society, his address on "Folk Poetry in America" was read by Dr. Charles Peabody.

Many of the important papers read at the joint meeting are represented in this report by abstracts. These are:

Investigations among the Plains Indians: CLARK WISSLER.

A preliminary statement of the general plan

for work by the American Museum of Natural History among the Northern Plains tribes and the southwestern Indians was presented in brief, followed by a general comparative résumé of the results in the Northern Plains. Attention was called to recent evidences for the former use of pottery by the Blackfoot Indians and its apparent similarity in type to that used by the Menominee and the Saulteaux. The chief discussion, however, was confined to ceremonial bundles of the Blackfoot, special attention being called to the great uniformity of structure in the rituals belonging to the same, suggesting that all had a common origin. Certain striking similarities to Pawnee rituals were pointed out as well as correspondence with the Cheyenne. It was noted, however, that the Blackfoot bundles seem to be of a distinct type as opposed to those of the Menominee, Winnebago, Ojibwa, Sauk and Fox, etc. The individuality of the Blackfoot bundle scheme is shown in the peculiar transfer conception by which a bundle may pass from one person to another without restriction. There was also an investment feature in the transfer, that is, while considerable property changed hands when the bundle was secured, the owner could at any time secure an equivalent return by transferring the bundle to another. The transfer-investment character of Blackfoot rituals has not so far been reported among other tribes and may remain tentatively as a Blackfoot characteristic.

Problems in the Ethnology of the Crow and Village Indians: ROBERT H. LOWIE.

One problem in the ethnology of the Northwestern Plains is the extent of Caddoan influence. It is certain that one form of the pipe ceremony was introduced by the Arikara among the Hidatsa and thence traveled to the Crow. It is further possible that the origin of the earth lodge among the Hidatsa and Mandan is due to the same tribe, and accordingly it is necessary to study the Arikara-Pawnee culture in order to ascertain what other elements of the culture of the Upper Missouri may be reasonably traced to this source. A second problem suggested by a comparison of the Hidatsa and Crow is that of cultural differentiation among genetically affiliated tribes. The Crow and the Hidatsa are linguistically very closely related and must have separated in relatively recent times; nevertheless, the main features of their social and ceremonial life differ to such a degree that a purely cultural comparison could not satisfactorily establish a genetic relationship between them. A third problem is the

character and development of the "age" societies. It appears that certain features of these societies are widely diffused over the entire Plains area, while the system of age grades is confined to but five tribes. The essential factor in entering the age societies is purchase. An historico-critical investigation of the conceptions of these societies expressed in the writings of Maximilian, Schurtz and Kroeber is highly instructive as to the methods employed in ethnological thinking.

The Principle of Convergence in Ethnology: ROBERT H. LOWIE.

Dr. Graebner in his "Methode der Ethnologie" denies that the principle of independent development is logically on a par with that of historical connection in the explanation of resemblances. He also regards convergent evolution as involving assumptions as to a mystical psychological unity of mankind. Neither of these views is justified. More especially, the apparent mysticism in the doctrine of convergence disappears at once if the supposed identities are recognized not as ethnological realities, but as logical abstractions—not as homologies, but as analogies.

Notes on the Material Culture of the Rio Grande Pueblos: HERBERT J. SPINDEN.

The cultural conditions found in the southwest may be explained by divergent evolution due to a different economic use of the land. The aridity acted as a natural barrier against a people in the hunting stage, becoming one in the agricultural stage. The change could only be accomplished by cooperation in the building of irrigation ditches, etc., and by corresponding changes in the habits of life.

The nomadic tribes used the soil extensively. They gathered natural fruits and followed the chase. The sedentary tribes used the soil intensively. They irrigated the soil, built permanent villages and cultivated the household arts of weaving and pottery making. The minor features of material culture show the fundamental bond between the sedentary Indians of the southwest and the nomadic Indians of the Plains and Plateau. The following rough classification of the arts may be of interest.

Arts largely resulting from the change to sedentary life: architecture; pottery; weaving; decorative symbolism; use of white clay in cleaning buckskin; rattles of deer hoof, etc.; use of heart line in realistic art; occurrence of horned and plumed serpents in realistic art; use of sand paintings.

Features of extremely wide distribution not given in the above list: coiled basketry; bags or cloths of yucca fiber, Indian hemp, etc.; fire drills and pump drills; tubular pipes; grooved stone axes, arrowheads, etc.; flageolles, flutes, drums, tambourines, etc.

Features that are probably of southern origin: metates; compound arrows with reed shafts; corn and other agricultural products; details in textiles and ceramics.

Features suggesting connections with the Plains and Plateau: buffalo shields and covers; war whistles; scalping knives; war lances and other regalia; deerskin shirts and leggings; porcupine quill decoration; decoration of buckskin by perforation; buffalo and elk hide blankets with decorated strip; rabbit-skin blankets; war-bonnets; sinew-backed and horn bows; double quiver with separate bow and arrow cases; grooved arrow rasps and polishers; flint flakes of bone; perforated arrow straighteners; self arrows with blood grooves and painted rings; wickerwork carrying baskets built on a foundation of two crossed sticks; fish trap made by converging walls and willow mat; mats of sewn tule; saddle made of two long narrow cushions; skin dressing tools; use of brains in tanning.

Some Aspects of the Negro Problem: ALBERT ERNEST JENKS, University of Minnesota.

Immigration.—Since we have a serious negro problem is it reasonable that this problem be made more difficult by admission into the United States each year of an increasing number of un-Americanized immigrant alien negroes?

There are no United States laws against such immigration. Just short of 40,000 such persons have come to this country in the last ten years; in 1911 we received 6,721. They come from near at hand—three fourths coming from the West Indies. The West Indies have nearly 6,000,000 negroes, any of whom may come to the United States. America debarbs oriental peoples, not because they are inferior, but because they and their culture are so different from American people and culture. For the same reason we should exclude the "African black." He should also be excluded because his admission is unfair to the white and also to the negro American—since he makes even more difficult one of America's most perplexing problems.

Miscegenation.—There are two forms of negro-white miscegenation: (1) Legal marriage, per-

mitted in twenty-three states where the unions are largely between negro men and white women; (2) illegal, more or less temporary unions, usually between white men and negro women. Investigation in a certain area shows that 65 per cent. of the white wives of negro men are foreign-born girls—usually of Teutonic peoples. Over two per cent. of children are born to these marriages. The result of both these forms of miscegenation is an increasing number of mulattoes cemented by color and prejudice to the negro race, while by inheritance they are endowed to a considerable degree with Anglo-Saxon initiative, will, ideals and desire for a square-deal—which, because of their color, they can seldom get. These mulattoes are the migrants in the north and west of the United States; they are more migrant than the restless, foot-free white American. The mulatto is the chief factor in the negro problem; the problem is bound to increase, then, in geographic area, in number of discontented negroes, and in its intensity, hand in hand with the increased flow of Anglo-Saxon blood into the veins of this new American man. All forms of miscegenation between the two races should be made a felony, punishable for one offence; and the father of children born to one white and one negro parent should be held to support and educate such children.

Who is a Negro?—The negro should be defined uniformly, so that there would be no question of the legal and racial status of any given person, no matter in what commonwealth he may be. To-day there is no such uniformity of laws.

Murderous Race Riots.—The white man's passion against the offending, or suspected, negro is often nothing short of blood vengeance against the negro race. This is seen in the fact that assault against the virtue of a white woman is only one of some three dozen offences for which negroes are annually lynched. In many of these lynchings and burnings murder is not committed in the frenzy of the moment; the mob starts out to lynch or burn—the crime is premeditated. If America is to train her annual armies of immigrant recruits into law-respecting and law-abiding citizens, she must punish to the limit necessary all participants in murderous race riots.

Education.—Each negro child should have, so far as public and private schools are concerned, an equal opportunity with the white child to make of himself all that he is capable of being.

Investigation.—A commission should be selected to study every aspect of the negro problem. This

commission might well be financed by private funds so as to keep it from the almost certain bias of politics and sectionalism.

Presentation of Specimens of Eolithic Form from Salinellas (Gard), France: CHARLES PEABODY.

Dr. Marignan (Hérault) recently discovered chipped flints, which he considers to be eoliths. In spite of their localization the specimens are eoliths in facies probably rather than in actual age. Noteworthy is a series of discoidal hammers. The natural fractures of the flint and the outlines of the stones were carefully noted and compared with specimens from the Kent Plateau, Boncelles, etc.

Cacimbas of the Isle of Pines (Cuba): J. WALTER FEWKES.

The word *cacimba*, varying in form, apparently found in several linguistic stocks, is widely spread in aboriginal Latin-America, from the Andes in South America to the larger Antilles. It is supposed by most linguists and by natives generally, to be a purely aboriginal term signifying a receptacle or, in a slightly changed form, possibly another word, a pipe. In the Isle of Pines it is applied to a hill with reservoir-like depressions, and to a landing place called "Embocadero de los Casimbas," near Sigüea Bay, but mainly to certain artificial subterranean, vase-shaped receptacles occurring in various localities. The *cacimbas* are always constructed under ground, where they are either cut out of the solid rock or built of rude masonry. In a few instances the lower portion is excavated and the upper or neck is formed of a wall of undressed stone.

About thirty of these structures were examined in various localities in the Isle of Pines, others being reported from the south coast of the western end of Cuba. They occur near to or far from the banks of rivers, some distance from the seashore, in woods or open fields, singly or in clusters. The largest number was found near Nueva Gerona and Santa Fé, the latter situated in the middle of the island, where considerable quantities of turpentine were once made, as indicated by remains of ovens of undoubted Spanish manufacture. Isle of Pines *cacimbas* are accompanied, especially where the surface of the ground has not been greatly disturbed, by low circular mounds depressed in the middle but with raised rims varying from twenty to thirty feet in diameter, situated about the same distance away and overgrown with guano prieta or black-bark palmettos and under-

brush. The *cacimbas* average about five feet in depth; four feet is the greatest diameter and the narrowed, neck-like entrance, the rim of which is sometimes elevated a foot above the surface, has an orifice large enough to admit the human body. Their inner surface is generally smooth, plastered and blackened, the mortar in which the stones are laid being black, as if impregnated with tar. The floor is flat, circular, sloping slightly to the center, where, in one instance, there is a groove connecting with a covered trench which opens on the hill-side. A thin layer of tar was found covering the floors of several examples. When these *cacimbas* were cleaned out they were discovered to be about half full of rubbish, damp soil, debris and decaying leaves. No aboriginal implements or human bones occur in any of them, but there were in one a few fragments of Spanish pottery and the broken jaw of a domestic hog, with other animal skeletal remains. The moist earth in some *cacimbas* is a favorite habitation for the Cuban crayfish, many specimens of which were taken from one of these structures near Mr. Allnutt's home a short distance from Nueva Gerona. Trenches dug diametrically across the adjacent mounds revealed black layers containing ashes and charcoal with fragments of tar just below the humus, but no walls or aboriginal objects were observed in these mounds.

The Isle of Pines *cacimbas* are almost universally, and without hesitation, ascribed by the natives to the Indians. It is sometimes held that they were constructed by Caribs as storage places for tar and other objects, as their name implies, and one intelligent person affirmed that the builders were Indians working under Spanish direction. It is claimed by others that they were made by white men and were used as receptacles for turpentine, the neighboring mounds being the places where this substance was manufactured. One of those who held this opinion claimed that pine logs were so laid on the mound that their ends were brought to the center and application of heat caused tar to ooze from them into a pan or small receptacle, from which it was transferred to the *cacimba*. No reliable facts that would prove or disprove any of the current theories were obtainable, but it is certainly strange, if these structures are of Indian manufacture, that no aboriginal objects or implements were ever found with them. Under the circumstances their origin remains one of the unsolved problems of the West Indian culture history. However, the opinion of a very intelligent native of advanced years, who claimed

that he was a descendant of one of the Comarco Indians of the Isle of Pines, is worthy of record. He said that he had been told by his father, who came from Camaguey, that they were constructed by the Indians and that he had never heard that white men made them or used them as turpentine receptacles. Two cacimbas, situated about three miles from Nueva Gerona where the road to El Bobo forks, sending a branch to McKinley, are called Cueva de los Indios, although there is no cave in the vicinity.

The morphological resemblance of the cacimbas to the chultunes of Guatemala and Yucatan is great. Cacimbas are ordinarily smaller and differ from chultunes in not containing aboriginal objects. If the structures are Indian and pre-Columbian, of which I confess doubts, this unique fact is significant as being the only resemblance thus far found in the antiquities of western Cuba and the neighboring peninsula of Yucatan. No evidence can be presented to indicate that they are related to the cave men of Cuba or to those Indians whose skeletal remains were found in the Cueva de los Indios near Nueva Gerona.

The Chultunes of Northern Guatemala: ALFRED M. TOZZER.

The subterranean cistern-like reservoirs called "chultunes" of northern Yucatan as described by Mr. E. H. Thompson in his paper on "The Chultunes of Labna" seem to have been intended primarily for the storage of water. They are found in most cases in regions where there are no natural sink-holes or cenotes or other available source of water. In a few cases they may have been used as burial places.

In northern Guatemala the country is well watered and there is little need of cisterns for the storage of rain-water. The chultunes, however, are far more frequent than in the peninsula to the north. A large number were mapped along the route taken by the Peabody Museum Expedition of 1909-1910. They seem to stretch in long lines connecting the various ruined centers in this region. In addition, several were found in close proximity to the cities themselves.

The chultunes of this region are of two types, the simple cistern-like subterranean chamber similar to those in the north and the lateral-chambered chultun. This second type is met with far more frequently than the first and consists of a room excavated out of the rock and opening from the bottom of the shaft.

From the fact that these chultunes occur in

many places where there is an abundant supply of water, it may be argued that the storage of water is not the primary object of these subterranean rooms. Some were no doubt used as burial places. From a large lateral-chambered chultun at Yaloch a large collection of excellent Maya pottery has been taken out. From the manner of occurrence it seems probable that there was a burial here on the floor of the chamber, although no bones of any kind were found still existing in the three feet of earth which had been deposited in the chamber. Three examples of a tall bottomless type of vase were found which are unique. Covers to jars were also common.

Chultunes were also excavated at Chorro, Nakum and Holmul. From the large number of extensive groups of ruins in this area and the hundreds of small mounds and chultunes connecting these centers with one another, together with the examples of pottery from this region, it may be seen that here in northern Guatemala we have perhaps the most important center of the Maya culture.

The Mexican Maize Season in the Codex Fejérváry-Mayer: STANSBURY HAGAR.

On sheets 33 and 34 of the Codex Fejérváry-Mayer (Loubat edition) are two series of symbols including four paintings on each page, two above, two below. The four upper symbols, reading from right to left in the usual manner, picture the maturing of the maize crop during a period of four months: the lower symbols represent the deities governing the months mentioned. But the writer has presented evidence in a previous paper upon the "Elements of the Maya and Mexican Zodiacs"¹ that this sequence of deities also represents the zodiacal signs Cancer, Leo, Virgo and Libra. These signs correspond with the months July, August, September, October, which correctly represent the maize season described upon the Mexican plateau.

A Study of Biological Paleogeography in its Bearing on the Origin of Man in America: AUSTIN H. CLARK.

From a study of the geographical distribution of animals we find indicated: (1) an Indian Ocean land extending from the Lesser Sunda Islands (Sumbava to Timor) to Ceylon, Madagascar, the Mascarene Islands and southeastern Africa; (2) an Afro-Antillean land extending from the Mascarene Islands and Madagascar across south cen-

¹Sixteenth Int. Cong. of Americanists, pp. 277 et seq.

tral Africa to the West Indies and the highlands of South and Central America (including the Galapagos Islands); (3) a South Sea Island land bounded by Formosa (Taiwan), southern Japan, the Hawaiian and Marquesas Islands, New Zealand, New Caledonia and the Lesser Sunda Islands (but not New Guinea), possibly including Java, Sumatra, Borneo, Celebes, the Philippine Islands, and the Malayan region; (4) a large Australian continent including Australia, New Guinea and the Aru Islands (but not the Ki Islands nor the islands further west or north); (5) a connection between southern Australia and the Magellanic region; and (6) a very broad strait including the entire Behring Sea and the adjacent Arctic Ocean as far at least as Wrangel Island and the New Siberian Islands. 1 and 2 became disintegrated and disappeared at a very early date, probably long before the existence of man; 3 became submerged, first on the eastern border, very early, also probably before the existence of man; 5 disappeared very early, but persisted late enough so that much of the southern South American fauna entered that continent from Australia by means of it; it is possible that man also entered South America along this path and later entirely lost his Australian character through amalgamation with the true American stock from the north; this would account for certain Australian characteristics found among the Fuegians; 6 persisted long after man inhabited eastern Asia; it was thus probably the path by which man entered America.

The People of Sandao-a: ELIZABETH H. METCALF.

In the extreme southern part of Mindanao, the most southern and largest of the Philippine Islands, on the foothills of the beautiful volcano which the Spaniards call "Apo" (The Grandfather), live the Bagobos, a pagan tribe of high mentality, docile natures, spectacular in dress, and in some respects very primitive. They call the volcano "Sandao-a" (pronounced Sandowa), "The Sulphurous One." These Bagobos are a mountain people, and to a certain extent nomadic. They understand only the cultivation of mountain rice; and as this necessitates the cutting of a new bit of forest each year for their rice plantation, they are likely to move also each year into the vicinity of the new rice field. Recently they have been brought together into villages by government order. Although the American arrangement of the tribal wards somewhat curtails the political power of the present head Dato, he is still highly esteemed by both natives and Americans.

Formerly the wealth of the people was in slaves, animals, aguns and fine clothes. The days of slavery are past; the aguns, or big gongs, they still possess. These are their most important musical instruments; and the magnificence of tone coloring of many large gongs played together is quite indescribable. The Bagobos have other instruments of percussion, wind and strings, but these large gongs are also for them their medium of exchange, and a man's wealth is usually reckoned by the number of gongs he possesses.

Their clothes are made from hemp fiber, which the people weave into a cloth, unique in manufacture, and which lends itself admirably to the artistic fashion of ornamentation employed by these people. Of the old embroidery of cross-stitch on coarse Chinese cotton cloth, which the women understood fifty or more years ago, there are still a few samples to be found; but the present style of ornamentation consists of an applique in various forms of bright-colored cloth, of embroidery, of beads and tiny pearl disks sewn on in designs. The beads the people purchase from the Chinese merchants, the pearl disks are made from shells, found farther back in the mountains by another tribe living there.

The houses are always built up from the ground—sometimes of bamboo prepared in various ways, sometimes with the frame of wood with the leaves of certain trees laid on thickly for the roof and more openly for the sides. The entrance to the house is by a notched stick or by a ladder, and the furniture is exceedingly simple. A peculiar feature, especially of the houses of the aristocrats, is the different floor levels. At the extreme end of the house, opposite the door, the floor is often raised from 6 inches to 3 feet and the whole width of the house. This place is for guests and for the heads of the family. I have seen a house of an important old Dato with three floor levels; on the highest level only the old Dato and his wife and such persons as they might bid, could come.

The fireplace is usually near the door, with bamboo tubes of water standing on end nearby; the better class have bamboo frames of various kinds for holding dishes, and always in its proper place in every house, even the poorest, is the "Tambara," the little bowl containing the usual offerings, the simplest form of house altar. The greatest of their altars, the "Pat-a-non," or war altar, is also a house altar. The erection of this altar is allowed to only a very few high Datos and is connected with their most important fes-

tival, which occurs some time during rice planting. The most significant ceremonies formerly attended this festival, which might last from two days to two weeks; but as in other regions of the earth, so here, the incoming of commerce and civilization kills the ancient culture; and it is probable that if it is given at all in its entirety, it is only in the remote regions of the mountains, that this great festival of the "Ginum" is now observed with all its elaborate ceremonies. The Bagobos have other altars for different places and different occasions; altars for the planting of their corn or rice; for the cutting of their crops; and very often they place an altar with their offerings near a great tree or a beautiful spring or running water, especially if the water is to be used for any ceremony of purification.

A Note on the Personification of Fatigue among the Nez Percé, Kutenai, et al.: ALEXANDER F. CHAMBERLAIN.

In common with other authorities, Dr. Paul Ehrenreich, in his recent volume, "Allgemeine Mythologie" (Leipzig, 1910), takes the view (p. 159) that personifications of abstract ideas, etc., are of little mythological significance, being almost entirely of cultural or ceremonial import. Such personifications as do exist he regards as not primarily personifications of such qualities, but originally representations of lunar personalities, as, *e. g.*, in the cases of the Greek Hermes-Autolykos (gambling and pleasure) and the gambling-deities of certain North American Indians. According to Ehrenreich, the hunting-gods are "not really personifications of the hunt, but almost always the moon-god, or at least a being furnished with lunar traits" (p. 160). But this is going too far in the way of panlunarism.

Among interesting personifications of abstract qualities among the North American Indians are *sleep* among the Ojibwa (Schoonercraft) and *hunger* among the Shushwap (Teit). Another case is that of *fatigue* among the Nez Percé and the Kutenai.

As Bartels ("Medicin d. Naturv.," Leipzig, 1893) notes (p. 235), citing Bancroft ("Native Races," Vol. I., p. 284), among the Nez Percé there was a ceremonial participated in annually by all the males of the tribe between the ages of 18 and 40. The ceremonial, which lasted for from 3 to 5 days, had, as its most noticeable element the pushing of willow-rods down the throat into the stomach, this being followed by hot and cold baths and fasting. The firm opinion of the Indians is that they thereby obtain great bodily

strength and power of resistance to fatigue. The ceremonial is held in order to overcome *Mawish*, the spirit of fatigue. This is the Nez Percé "spring-medicine," reported on recently by Dr. Spinden. There are certain identities and resemblances in Kutenai and Nez Percé mythology, etc., that deserve careful study (one curious item is the presence in each of a character with *one leg*). *Mawish*, of course, is the Chinook jargon word for animal (*e. g.*, deer)—and the deer figures prominently in the dances, etc., of the Kutenai.

Initial and Terminal Formulæ of Kutenai Tales:
ALEXANDER F. CHAMBERLAIN.

Although, in the adverb *pik'aks*, the Kutenai language has a word corresponding to our "long ago," "once upon a time," etc., so familiar as an initial formula in the tales and legends of many lands, this term does not appear as the customary beginning of such stories as have been recorded in the native text.

In narration the Kutenai employs the "historic present," as the grammarians term it, adding thus to the vividness of the story told. The great majority of the tales begin with a verb in the present tense, therefore, not with such a phrase as our "once upon a time," with its verb in the past tense. Examples of Kutenai initial formulæ are:

Kānaquē Skinkūts	= Coyote is traveling.
Kānaquē tlántlā	= Grizzly-Bear is traveling.
Kāusākā'ne Wōtak	= Frog is there.
Kōnitlāinē Skinkūts	= Coyote is in his house.
Kōnitlāinē G'ōtsāts	= Chipmunk is in his house.
Tsināqē Skinkūts	= Coyote sets out (starts off).
Kāktlūnām'nē	= There is a village.
Nātlqōnē Djāis	= He carries his brother on his back.

Very seldom is the order as above indicated inverted, as *e. g.*, Mitsākākas Kāusāk'ā'nē, "The Tomtit is there." The "Tale of Seven-Heads" begins: Wistātlātlām sāhānē, "Seven-Heads is bad"; a tale of the owl, Kūpi tsākētlāine, "The Owl is a great thief." The term āwātīlnē, "together," begins a tale, as, *e. g.*, Āsmātīlnē tsināqē Skinkūts āqi Nāik'yū, "Coyote and Fox set out together," although the formula Skinkūts āsmātīlnē, etc., is also used. Among the Kutenai, as with some other Indian tribes of the Oregon-Columbian region, the coyote who figures so largely in myth and legend is represented as being "on his travels"; so, too, with certain of the other animal characters. Kānaquē Skinkūts is the typical be-

ginning of most of the stories in which he plays the chief rôle; tsinâqê, "he starts off," "he sets out," is another initial formula of frequent occurrence in the animal-tales. The word Kâusâk'ainê signifies "he is at," "he stays," "he stops," "he is there," "he is." Such beginnings are Kônitlâinê, "he is in his house," "he is at home," and Kâktlânâm'nê, "there is a village," are quite picturesque. Often there is no terminal formula in Kutenai stories. A common term, however, is táqas, "ended," "enough," "done," "finished." The phrase tlâtlônê, "there is no more," also occurs. The terminal Kâpêť, used by some of the Indians, seems to be the Kópêť of the Chinook Jargon, modified by supposed derivation from Kutenai K'âpê, "all."

The Allentiacan Linguistic Stock: ALEXANDER F. CHAMBERLAIN.

All the evidence in hand indicates that the language (extinct in the eighteenth century; represented by the "Grammar and Vocabulary" of de Valdivia, published in 1607 and 1608, reprinted in 1894 by Medina) of the *Allentiacs* or *Huarpes* forms an independent linguistic stock, the *Allentiacan*, as it may be called. The *Allentiacs*, according to Boman, were quite a savage people and unrelated to the tribes of the Andean valleys. This Argentinian people inhabited, at the time of the Spanish conquest, the plains about the great lagunes of Huanacache, extending probably to the western slopes of the Sierra de Cordoba, and southward to the northern parts of San Luis and Mendoza. The *Allentiac* linguistic material has been discussed by de la Grasserie (1900) and Mitre (1894 and 1909).

The Bororoan Linguistic Stock: ALEXANDER F. CHAMBERLAIN.

There can be no doubt of the status of the language of the Bororó Indians of Central Matto Grosso (Brazil) as an independent stock, as suggested by von den Steinen as early as 1886, or a little before that. Brinton in his "American Race" (1891) failed to recognize this, or had not noticed von den Steinen's statement, and classed them incorrectly as Tupian. It was only in 1888, as a result of the second Xingú expedition, that the identity of the so-called "Coroados" branch of the stock with the genuine old Bororo was established. Conflicts with the whites have sadly reduced the numbers of the Bororó. Their characteristic area, as defined by Frič (1906), is "the entire course of the S. Lourenço river as far as its

union with the Cuyabá, where they come into contact with the Guatô." Further north they occupy "both banks of the Araguaya right across the road that leads from Cuyabá to Goyaz." In the first half of the eighteenth century these Indians roved about the region of the Xingú-Araguay watershed in central Matto Grosso. Later on, the so-called "Borroró do Cabaçal" settled on the upper Paraguay. The vocabulary of 360 words, given by von den Steinen, in his "Unter den Naturvölkern Zentral-Brasiliens" (1894) is the most useful linguistic material of the Bororoan stock. Other vocabularies are given by Caldas (1899) and Frič and Radin (1906)—the last print also a vocabulary from Boggiani.

The Calchaquian Linguistic Stock: ALEXANDER F. CHAMBERLAIN.

The character of the Calchaquian language and the extent of the area over which it prevailed have been the subject of much discussion and dispute. Some have held that the Calchaqui, Catamarqueño, or Cacana tongue was nothing more nor less than a dialect or *patois* of Onechua, spoken in Tucuman, etc. Others seek to connect it with Aymara, Atacameñan, etc. The Calchaquis may have been a mixed people, as Lafone-Quevedo and Ehrenreich maintain. But there was an essential Calchaquian (or Diaguitan, as Boman prefers to call it) culture, and with it went a language, which was still spoken in the seventeenth century, and, from all appearances, seems to have been an independent form of speech, deserving rank as a linguistic stock. Boman (1908) failed to find any trace of the existence in Paris of the grammar and vocabulary of Calchaqui said to have been written by the Jesuit missionary Alonso de Barzuna (or Barcena) in the sixteenth century. The Calchaquian linguistic data consist of place-names, etc., discussed, *e. g.*, by Lafone-Quevedo, in his "Tesoro de Catamarquenismos" (1898). At its greatest extent the Calchaquian (rather than Catamarcan or Diaguitan) stock may be said to have occupied a territory of varying breadth, between about 23° 30' and 32° 30' S. lat. For the archeology of this region much knowledge is due to the researches of Ambrosetti, his colleagues and students.

Recent Opinion as to the Position of the American Indians among the Races of Man: ALEXANDER F. CHAMBERLAIN.

The author discussed briefly the various theories in the light of the scientific literature of the past

few years—the autochthonous, the European, the Asiatic. The protagonist of the theory of the autochthonous origin of American man is Professor Ameghino, the Argentinian paleontologist, who derives him from the higher simians in southern South America. Professor G. Sergi, the Italian anthropologist, who looks with some favor on Ameghino's views, recognizes—he takes a rather polygenetic view of human origins—among his separate human races a *facies Americana*. The old view of Boyd Dawkins (resurrected by him, in a somewhat modified form) that the Eskimo are the representatives or the descendants of European cave-man still finds favor in certain quarters, but the recognition of the interior origin (in the region east of Hudson Bay) of the Eskimo as demonstrated by Boas, etc., places this theory rather out of court. That the American race is simply a Mongolian type, a view once much in favor, has lost its standing since the results of the Jesup North Pacific Expedition have become known. The data acquired concerning the so-called “paleo-Asiatic” peoples (Chukchee, Konaks, Kamchadales, Yukaghir, etc.) of northeastern Asia and the peoples of northwestern North America, demonstrate that the “paleo-Asiatic” people, at least (as the Asiatic Eskimo did later) must have crossed from America to Asia long subsequent to the arrival of the ancestors of the American race from Asia (if they came by way of Bering's Straits, as now seems reasonable). The American Indians may thus be considered as an Asiatic people (sprung from the proto-Mongolian stock), considerably modified by their New World environment. By a reflux wave of migration they have “Americanized,” as it were, a large section of northeastern Asia.

The Mourning Ceremony of the Southern Paiutes:
EDWARD SAPIR.

The main ceremony of the southern Paiutes of Utah, Arizona and Nevada is an annual mourning ceremony or “cry.” The expenses of such a ceremony, which generally lasts for five days in June or July, are borne by two men, one of them a close relative of a recently deceased member of the tribe. Sometimes neighboring bands are invited to take part in the ceremony. The place of the mourning ceremony varies from year to year and is decided upon at a preliminary council meeting. The essential elements of the ceremony

are the singing of numerous mourning songs and the offering of valuables, such as baskets, articles of clothing and horses, in memory of the dead.

The songs, which are accompanied by rattles held by each singer, are to be classified into four sharply distinguished types, roan songs, bird songs, coyote songs, and mountain sheep songs. Each of these has its characteristic type of melody and accompanying movements on the part of the singers. There does not seem to be any idea of a grouping of the participants of the ceremony into four societies singing these different types of songs; one may join in the singing of any class of songs and leave one group of singers for another. There is, however, a song leader for each type of song. This merely means that certain people are proficient in the singing or composing of particular classes of songs. The texts of the songs are in comparatively few instances in Paiute, but belong to a language that is unintelligible to the singers. There is reason to believe that the types of songs, the actual song-texts, and perhaps the whole ceremony are borrowed from the Yuman tribes to the west. There is a possibility that the song texts consist of an elaborate system of burdens.

At various stages during the singing, which forms the major part of the ceremony, ceremonial “cries” take place which are conducted by a cry leader. On the last night of the mourning ceremony, during which it is forbidden to sleep, the articles which have been set aside as offerings to the dead are burned on a funeral pile; horses are shot, valuable articles which have been exposed as offerings may be taken by others and replaced by objects of less value. It is evident that the Paiute mourning ceremony bears considerable resemblance to mourning ceremonies of various Californian tribes.

Cephalic Type Contours: WILLIAM C. FARABEE.

The main object aimed at in all physical measurements is to find characters that shall be peculiar to the race or group of people under investigation. Under the old methods little attention was given to actual measurements of characters, except in so far as they aided in the determination of ratios or indices. The various indices for each individual were calculated and the average and range determined for the whole group. It was believed that these ratios were more constant than were the absolute dimensions and hence general conclusions were based upon the ratios obtained from short series.

Recently, improved methods have shown that these ratios have as wide range of variability as the measurements themselves and it has been found necessary to apply rigid statistical methods to the actual dimensions. The most constant characters of a large number of individuals must be observed and selected for measurement. In the past the head measurements have been considered of most importance and most constant. For the Harvard Expedition to South America De Milhau devised a cephalometer which allowed one to take measurements from the center of the auricular passage to any desired position on the head or face. For comparative group studies these dimensions were most satisfactory. Yet one very important factor was lacking, viz., the angle between the lines, which prevented any possibility of graphic presentation. To overcome this defect and to minimize as far as possible the importance of definitely locating all the positions mentioned, a protractor was attached to record these angles. This made it possible to locate the points to which the measurements were made, whether or not the positions were correctly determined. All measurements and angles were taken with reference to the horizontal plane of the Frankfort agreement. The vertical height is perpendicular to this plane and this line is marked zero in the scale.

When all results have been worked out according to correct statistical methods it will be possible to plot the *means* of all angles and measurements and when the ends of these lines have been connected by means of a spline a *type contour* will result. In the same way type contours of different related or unrelated groups in races may be made. These contours should be plotted on thin paper and superposed for comparative study. The advantage of the method is that it may be applied to the cranium as well as to the living head and direct comparisons made to determine relationships. Head measurements may be reduced to cranium measurements by allowing for the thickness of the cranial tissues.

Some Factors in the Differentiation of Human Types: ROBERT BENNETT BEAN.

Dr. Bean has studied random samples from four groups of mankind, Europeans, Africans, East Indians and Filipinos, and in each group three types that are similar in physical characteristics may be segregated. He has heretofore called these three types Primitive, Australoid and Iberian, but here they will be designated *A*, *B* and *C*, respectively.

Type *A* is small, brachycephalic and platyrrhine.

Type *C* is tall, dolichocephalic and leptorrhine.

Type *B* is medium in stature, mesocephalic or mesaticephalic and platyrrhine.

From the standpoint of growth other factors may be utilized to differentiate the types. It is known that the relative total leg and arm length increase from birth to maturity, the face increases in size, and the umbilicus descends. To make these factors relative we may use the length of the leg in relation to stature, the length of the arm in relation to stature, the size of the face in relation to the size of the head and the position of the umbilicus in relation to the position of the suprasternal notch and the symphysis pubis. Dividing the length plus breadth of the face by the length plus breadth of the head gives a cranio-facial index, which is low at birth and high at maturity. Dividing the distance of the umbilicus from the symphysis pubis by the distance of the umbilicus from the suprasternal notch gives the omphalic index, which is high at birth and low at maturity.

The three types may be assembled by the use of these factors according to the stage of development that each represents, as follows:

Type <i>A</i> Hypo-onto-morph	Type <i>C</i> Meso-onto-morph	Type <i>B</i> Hyper-onto-morph
	Relative total arm length	
Small	intermediate	large
	Relative total leg length	
Small	intermediate	large
	Cranio-facial index	
Small	intermediate	large
	Omphalic index	
Large	small	!

Type *A* is less developed than type *B*, and type *C* is intermediate.

Additional factors, mainly descriptive, have been utilized to differentiate the three types, the form of the external ear or pinna enabling one to classify any individual after close scrutiny. The distinctive differences of ear form refer particularly to the inversion or eversion of the outer rim of the concha, and the rolling in (forward) or rolling out (backward) of the helix. These changes are especially to be seen at the lower part of the ear in the region of the tragus and antitragus, and the helix and anthelix. The ear of type *A* has an inverted concha—the tragus and antitragus appear to be pushed in—and an inrolled helix, giving it a trumpet or bell shape. The ear

of type *C* is the reverse of this: the concha is everted—the tragus and antitragus appear to be pulled out—and the helix is rolled back at its lower part. The ear of type *B* appears to be intermediate between these extremes. The ear type is more distinctive than any other factor, and may be utilized more readily, therefore it is more serviceable.

The nose form is useful in the differentiation of type, although it is not so good as the ear form. The nose of type *A* is infantile. The bridge and root are wide and depressed, the nostrils flare and open forward rather than downward. The nose of type *B* is wide, long and high, with depressed root, straight, high bridge and nostrils that are wide and open only slightly forward and downward. The nose of type *C* is narrow, long and high with high root and bridge and nostrils that open downward.

The soundness of the teeth in types *A* and *B* is noteworthy, whereas the teeth of type *C* are very unsound.

Type *C* is more susceptible to diseases of the epithelial tissues, or those organs derived from the primary epithelium, such as the alimentary canal and the central nervous system; whereas types *A* and *B* are more susceptible to diseases of the mesothelial tissues or the organs derived from the primary mesoderm, such as the circulatory system.

Types *A* and *B* seem to be linked together in many respects, and in this they are different from type *C*, which seems a more clearly differentiated type than the other two. The three types differ slightly in the different groups of mankind, and resemble the type that is distinctive for each group. For instance, type *A* is distinctive for the Filipinos included in the present study, therefore types *B* and *C* resemble type *A* among the Filipinos; type *B* is distinctive for the Africans, therefore types *A* and *C* resemble type *B* among the Africans; and type *C* is distinctive for the Europeans and East Indians, therefore types *A* and *B* resemble type *C* among these peoples.

Type *C* apparently retains its characteristics in all the groups more specifically than do the other types. As this type is so distinct in at least the four groups thus far studied, besides forming such a considerable part of these four groups, Dr. Bean concludes that this type in the four groups originated from the same stock. He therefore believes that the tall long-headed blond northern European, the small long-headed brunette southern European, the tall long-headed, straight-haired black East

Indian and the tall long-headed, kinky-haired African are derived from this original stock. Their ear form is identical, and other factors confirm this evidence. Existing differences may be accounted for by hereditary, climatic and cultural conditions.

Linguistic Classification of Algonquian Tribes: TRUMAN MICHELSON.

Algonquian tribes linguistically fall into four major groups, to wit, Blackfoot, Cheyenne, Arapaho and Central-Eastern. The last may be subdivided into Central and Eastern. Of the Central subdivision, Ojibwa, Ottawa, Potawatomi and Algonquin form a special branch; and Peoria, etc., distinctly belong with them, but the latter are further removed from the others than any one of those from each other; moreover Peoria, etc., in certain respects are more archaic in their phonetics, and in some grammatical categories have more northern affinities. Menominee has the closest relations with Cree-Montagnais, though also is intimately connected with Fox, etc. Fox, Sauk and Kickapoo vary from each other but slightly; the differences are mainly in intonation and idiom. The first two are more nearly related than either is to Kickapoo. The last is closer to Fox than to Sauk. The three distinctly belong with Cree-Montagnais and Menominee as opposed to Ojibwa, etc. Shawnee is very close to Fox, Sauk and Kickapoo, but in certain respects agrees with Ojibwa, etc., and in others the Eastern subdivision. Natick clearly belongs with the Central and not the Eastern subdivision. In some categories it has affinities with the Ojibwa branch, but in others it is varied; and has some marked characteristics of its own. Delaware decidedly belongs to the Central and not the Eastern subdivision despite the popular notion to the contrary. The material in Zeisberger is a medley of Unami, Unalachtigo, Munsee. It is sufficiently clear that the linguistic relations of these were different; but the existing material is so unsatisfactory that it is premature to make any definite statement. The Eastern subdivision consists (to-day) of Micmac, Passamaquoddy, Malecite, Penobscot, Abenaki. Micmac is specialized in that it employs a conjunctive instead of independent mode; but the popular notion that it differs widely from the other members of the subdivision is mistaken, as is the belief that the Eastern subdivision belongs with Delaware. On the contrary the relations of the group are distinctly with Fox, etc., and Shawnee.

Dr. Michelson's paper is to appear in amplified form as one of the "Accompanying Papers" in an "Annual Report of the Bureau of American Ethnology."

The Status and Development of Canadian Archeology: HARLAN I. SMITH.

The archeological work of the Geological Survey since June 15, 1911, the date of Mr. Smith's appointment as dominion archeologist, has been divided into two main groups—the activities for diffusing archeological knowledge by such means as museum exhibits, guide books and lectures, and those for increasing such knowledge by exploration, original research and systematization.

The national collections have been classified tentatively into groups corresponding to the five ethnological culture areas. This grouping may be modified with the progress of research. The collection from the southern coast of British Columbia and the one from the southern interior of British Columbia are representative, and the collection from Ontario is large. The other provinces of the Eastern Woodlands, the Plains and the Arctic are hardly represented at all, and there are practically no data at hand concerning them. Popular guides have been prepared for the two western archeological areas, and work is progressing upon similar guides for the others. A series of lantern slides illustrating the archeology of Ontario has been made; general and topical labels for the collection are in the hands of the printer; duplicates of these will probably be furnished to the other museums throughout Canada, which with duplicate specimens, casts and photographs, when supplied to these museums, will make the archeological work truly national.

An archeological survey of the dominion is being organized, a reconnaissance has been made of some of the village sites in Ontario, and a survey of Brantford Township has been completed by Mr. W. J. Wintemberg. A scheme for systematizing and digesting the scattered and incomplete archeological data at hand and to be received in the future has been inaugurated. The cooperation of railroad officials, the northwest mounted police, Indian agents and geological explorers has been secured.

It is proposed to explore the less well known parts of Canada, beginning with intensive exploration at one site in each of the great cultural areas, in order that the results in the way of collections and monographs may be used as standards to which to refer for identification the results of

future exploration obtained in bordering areas where we may expect to find mixed or superimposed cultural material.

It is planned in the near future to make a reconnaissance of the Plains from which there is practically no material to-day available, to continue scientific exploration into the northern interior of British Columbia, using the Grand Trunk Pacific as a base, and to do an intensive piece of excavation along the St. Lawrence. Next the shell-heaps of the Atlantic coast may be examined.

The papers read of which the secretary was unable to obtain abstracts were:

The Anthropology of the Pueblos: A. HEDLIČKA.

To appear as a bulletin of the Bureau of American Ethnology.

Notes on the Words and Music of the "White Captive" Ballad: CHARLES PEABODY.

Relation of the Soil to Agricultural Practise.—The comprehensive study of agricultural questions which has arisen in recent years has revealed the necessity for accurate information on the character and distribution of soil conditions. It is being more clearly recognized how fundamentally the soil enters into all questions of agricultural betterment, both scientific and practical. Not only does the intelligent management of the soil rest upon a proper appreciation of the inherent physical, chemical and biological variations in soils in different parts of the country, but the suitability of these to different crops, the adjustment of the crops which can best be produced to the business organization of the farm, its size, equipment, money product, transportation and market facilities, and the social life of the community are involved. The application of the results of the investigation of the institutions for agricultural research—the experiment stations, the colleges of agriculture and the federal and state departments of agriculture—must take account first of all of soil conditions. Types and varieties of crops, methods of culture, tillage, drainage, irrigation and fertilization give better results upon some types of soil than upon others. Those which are well suited to one soil may be a total failure upon some other soil. The experiment stations have often confined their study to one or two types of soil on the central institution farm. It is only within very recent years that the importance of carrying on investigations at substations, upon the several typical soil

MAN intended for publication and books, etc., intended for review should be sent to the Editor of SCIENCE, Garrison-on-Hudson, N. Y.

formations which may exist in their territory, has been recognized. In all these and many other even larger questions a knowledge of the variety and distribution of the soils of a territory is of prime importance.

Principles of Classification.—The study of any group of facts or phenomena involves an understanding of the properties in which they may differ, and the systematic representation of these differences requires that the properties of importance be arranged and classified with reference to some controlling interest. Soil is no exception to this general rule, but the application of these principles in the field description of soils in a practical way and from the agricultural point of view presents many and complicated problems.

Definition of Soil.—In the discussion of the classification of soils, the soil should be viewed very broadly so as to include any portion of the earth's surface capable of producing plants. It includes thin, stony material as well as that of great depth and friability. It includes desert regions as well as humid regions. It includes the material as deep as any influence is exerted upon plants growing on the surface.

Requisites of Scheme of Soil Classification.—The classification of soil to be of the largest value should effect the accurate separation of materials with reference to all important inherent agricultural differences. This statement indicates the breadth of the point of view to be taken. It is that of the farmer—agriculture in its broadest sense. The classification should not be confined to any particular section of plant production. It should apply to flowers and forests as well as wheat and cotton. It should have a place for the roughest mountain region as well as for the most intensively tilled garden. To be less comprehensive is to invite arbitrary judgment and corresponding inaccuracy in

the application of the scheme in the field. The distinctions with reference to plant growth and agricultural practise which should be made are differences in, first, chemical composition, including total content of plant food, amount of lime, amount and condition of the organic matter and the solubility of all these, including the presence of alkali salts; second, physical properties including texture, structure, color, moisture capacity, aeration and temperature; third, the climate under which these properties exist. These distinctions which will determine natural plant growth will also make sufficient provision for agricultural practise necessary to produce domestic crops.

The ideal result of the scheme of soil classification is to separate all soil material into types or individuals which are uniform in their agricultural value and distinct from every other type of soil. The soil type must be the unit and the primarily important separation in the scheme. Once the types are recognized they may be grouped according to any selected properties, irrespective of those involved in arriving at their identity.

Difficulties in the Field Separation of Soils.—Having pointed out the properties with reference to which soils should be classified, the next problem is to apply these in a systematic way in the field. Herein arise two kinds of difficulties: First, to classify soils directly by their properties for plant growth is impracticable. Take chemical composition, for example. To classify soils upon the basis of chemical analysis of samples of every acre or even every ten acres is impracticable because of the large amount of labor and time involved. To directly determine the moisture capacity, temperature and other essential factors of plant growth presents similar practical difficulties. The direct

method must, therefore, be set aside. The important crop-producing properties must be correlated with some group of characteristics of the soil which are more easily recognized and grouped, and by this means arrive at individual types of soil which have some measure of agricultural unity and value. The more perfect this correlation of properties the more satisfactory will be the result. The characteristics of the soil which have been most often selected for correlation with its crop-producing properties are the geological. Second. Herein lies the second group of difficulties, namely, in establishing the correct relation between crop-producing power and geological origin, and also in the accurate separation of soil material along geological lines, due to the complexity of the geological processes and materials involved. Attention should be directed here to a point often overlooked, namely, that the separation of soils along geological lines is secondary to their separation according to crop-producing power. The method is an incident to the result, however interesting it may be as a part of the science of geology. Much confusion in work has resulted from the failure to sense this distinction. The soil type is a geological element in the structure of the earth and as such is legitimately investigated by the geologist. Unfortunately, for agricultural purposes, the geologist has seldom carried his separations far enough, due probably to the fact that he has not had the agricultural point of view and, therefore, has not appreciated the kind of distinctions which are demanded for farming purposes. This may be termed the agromomic point of view.

Principles which have been used in the Classification of Soils.—The soil has been classified from many points of view. Em-

mons¹ studied the soils of New York between 1835 and 1840 and made somewhat extensive chemical analyses of the soils in the several regions into which the state was divided. This is probably the most extensive of the early surveys and combined the chemical composition with geological origin in arriving at the agricultural separation, a method generally employed by investigators working in this field. The physical properties of the material were also recognized as important, but these several factors were not correlated in any definite way. Owen and Peters² made a very comprehensive study of the chemical composition of the soils of Kentucky. Hilgard³ has made the largest collection of the chemical analyses of soils available in America, in connection with the investigation of the cotton soils, and the soils are classified in the field and indicated on maps with reference to the native vegetation. The mode of formation and physical properties received consideration. Shaler⁴ in an article published in 1891 called attention rather definitely to the relation between the processes of soil formation and the character of the material and pointed out correlated types of plant growth.

In foreign countries a number of men have studied the problem of the practical classification of soils and of these the Russians have been most successful. Dokou-

chayev with his pupils,⁵ the most prominent of whom is Subertzev,⁶ studied these questions for many years and arrived at what may be termed the most perfect and comprehensive scheme devised up to the present time. Theirs is a genetic system based upon climate, the formation of the soil, and the apparent properties. It was rather a statement of broad groups than the designation in systematic order of the factors, which give rise to agricultural differences in soils.

The credit for definitely correlating the physical properties of the soil with its agricultural belongs chiefly to Whitney⁷ and his associates. By his work the textural properties of the soil, through their influence on the moisture capacity and general climate of the soil, were shown to have a very determinate effect on the crop-producing power of the soil. The adaptation of natural vegetation and of domestic plants largely reflects these properties. Grass is shown to be generally identified with fine-textured soils, corn with loams and truck and other special crops with rather light sandy loams.

The Federal Soil Survey.—In 1899, as chief of the United States Division of Soils, Whitney began the classification and mapping of soils in the field according to their evident agricultural value. At first the physical properties were used almost exclusively as the means of separation. This survey work expanded and many men were employed in the field. Gradually the scheme of classification expanded, under the lash of necessity, keeping always to the fore the agricultural significance of each

separation. Over four hundred thousand square miles were surveyed up to the beginning of 1911, distributed more or less in every state in the union. These surveys have proved their value and more than anything else have demonstrated the necessity of such work as a basis in general agricultural investigations and in education. They have also exemplified the necessity of arriving at definite principles for the classification of soils which in their distribution have little relation to political boundaries. Following the lead of the federal government and as a supplement thereto, many of the states have taken up survey work, some independently and some in cooperation with the federal bureau. All this emphasizes the need for a common basis for work such as the committee on soil classification of the American Society of Agronomy is endeavoring to establish.

While of great value and proceeding upon a broad basis of separation of soil types designed to represent their chief agricultural differences, on the one hand, the work has not always been as accurate as it might have been and, on the other hand, it has not been properly understood or appreciated because the factors which are used in the classification of soils have never been accurately stated. Individual survey men have been left very largely to absorb the scheme of separation from contact with the older men in the bureau and to work it out for themselves from previous training and especially from experience in the field. Apparently the factors which are used in the separation of soils are not always recognized and the grouping of types is often not upon parallel lines or lines of equal significance. The properties which determine differences in value have not been clearly perceived. The corollary of inaccurate grouping is inaccurate boundaries of soil types. As an in-

stance of the first inaccuracy the coastal plain is put on a par with the soils of glacial formation, however justified this may seem to be from the point of view of agricultural prominence. In the same line is the correlation of material occurring in the Ohio River bottom in Mason County, Kentucky, with the Norfolk series which is a part of the coastal plain. (Since changed.) The most serious errors in drawing the boundaries of individual types result from failure to appreciate the factors upon which the larger separations are made. These difficulties are pointed out, not to minimize the value of the work done, for they weigh lightly against the large and fundamental value of the surveys which have been completed, and which in the main are sound, but rather with the purpose to illustrate the importance of stating as clearly as possible the factors which are used in the practical classification of soils and the comparison of these with what may be termed an ideal scheme of classification. It is objected by some persons that it is not possible to devise a perfect scheme which is applicable under all conditions. The important point is rather that we now have a fair understanding of the primary factors which produce agricultural differences in soil and that the use of these in the classification, representation and study of soils is of great practical value. We shall attain nearer a perfect system as we accumulate more information on the subject. All of the elements of soil separation which are mentioned in the following pages have been employed in the work of the Bureau of Soils, but they have not been given equal or uniform value.

The most comprehensive review of the methods which have been used in the classification of soils is that by Coffey prepared as a thesis for the doctor's degree in George

Washington University under the direction of Dr. George P. Merrill.

The aim of this paper is to organize the factors which have been used in the classification of soils and any others which appear to have a controlling influence on the agricultural value of soil into a scheme which shall point out the fundamental factors involved, and the relation of these factors to the distribution of soils in the field. The requisites and some of the limitations of such a scheme have been stated. It was noted that the crop-producing power of a soil is dependent upon its chemical and physical properties and the climate.

Statement of Plan of Classification.—The climate of a soil has two phases: First, the climate of the region in general, due to its geographic position. Second, the climatic conditions within the soil, due to the physical and chemical properties of the soil itself. Due to the latter two soils of different properties situated under the same general climatic conditions may present different climatic conditions to the plants growing upon them. The temperature and humidity of sand and clay may be very different, which is illustrated by the fact that one is termed an "early" soil and the other a "late" soil.

The physical and chemical properties of a soil are due to its mode of formation and the kind of materials used. The first include the time element or extent of operation of the processes and changes subsequent to the general formation of the material such as drainage, climate, etc. The second include the kind of rocks from which the soil material is derived and may be as diverse as the kinds of rock multiplied into the proportionate mixture of any combination of these. The scheme is, therefore, genetic and in its broader lines purely geological. The relation of these to agri-

geologists, especially those who have given much attention to soils, for example, G. P. Merrill.* These are (a) general weathering which gives rise to residual material. The type of weathering and the activity of the several forces will depend upon the kind of rock. (b) Decay acting upon organic material to give rise to cumulose deposits. It differs from weathering, since there is an actual building up of material due to biological activity and biological changes are dominant. These two groups taken together have been termed the *sedentary division*, since the material has not been appreciably moved. Where rocks are involved the soil is likely to rest on rock of the same kind as that from which the soil was formed. The physical as well as the chemical properties of the rock maintain much of their identity in residual soil—for example, quartz bands in gneiss rock and chert masses and other impurities in the different strata of limestone.

The remaining processes involve appreciable transportation of the material and have been grouped together as the *transported division*. Four great agencies of transportation are recognized.

(c) Gravity produces the slow sliding of material down rather steep slopes and in some instances it includes avalanche movement. The material is without organized structure and likely to be rather coarse and thin and of low agricultural value in both extent and adaptation.

(d) Water has been the great transporting and soil-forming agency. Many of the most famous agricultural portions of the earth owe their formation to water, notably the Nile Valley, the American coastal plain and the interior lake plains and stream valleys. It couples a wide range of transporting power with very decided sorting

and in the deposit of the material produces stratification. Thereby nearly all of the areas of soil of distinct textural unity have been derived. Fine clay and clean, uniform sand are equally identified with the agency of water. Stratification implies differences in successive layers, and a shift in the direction or velocity of movement of the water when a material was being laid down may produce great variation in texture, structure and chemical composition. These principles of variation are so well understood that much explanation is unnecessary.

It is worth while to recognize three phases of action of water according to its breadth, extent of movement and to some degree its character. These are oceans (saline waters), lakes and streams. The depth, uniformity and chemical character of the soil formed under each of these influences are likely to be distinct. While water gathers rock material from many sources, each body is likely to have certain characteristics of its material due to the region drained.

(e) Ice in the form of glacial masses has been an extensive and important agency of soil-formation adjacent to the polar regions and in high mountains. Some of the most famous agricultural portions of the world, such as much of the Upper Mississippi River Valley owe their character to this agency. Here again peculiar chemical, physical and, to some extent, topographic features are imparted to the material handled. The kind of rock encountered, the rate and direction of movement of the ice and the minimum of chemical decay and leaching have determined the agricultural features of many regions formed by glacial ice. The soil conditions in New York State especially exemplify these distinctions.

Ice does not accomplish sorting or strati-

* Merrill, G. P., "Rocks, Rock-weathering and Soils," pp. 411, 1897, Macmillan Co., N. Y.

fication and is likely to produce a range in texture and a degree of compactness of the lower part of the soil section not found in soils formed in other ways. It is often difficult to distinguish between material deposited by pure ice action and that modified by glacial water due to the melting of the ice.

(f) Wind has not been so distinctively a soil-forming agency as water and ice, though it has very generally contributed to the result.* Like water it effects sorting and stratification, but the range in texture of material carried is very much more narrow, the type of stratification is different, and the material has a wider areal unity in chemical and physical properties. The most distinctive soil formations whose origin has been referred to the action of wind are sand dunes and loess. The former represents a large amount of material which has been rolled along the surface of the ground. It is usually a fine sand and shows sorting to the extent that very fine material is almost wholly removed. While the origin of loess has been referred to the settling of dust from the atmosphere, the American deposits exhibit properties which cause the adequacy of this theory to be questioned. In northern China, where this material was first recognized, its origin was attributed by Von Reichtofen to the agency of wind. At any rate it is a distinct material and seems more closely associated with this mode of formation than any other. The possible chemical and physical properties of wind-blown material entitle it to recognition in the scheme of classification.

IV. *The Group—Source of Material.*—The kind of rock from which a soil is formed is generally recognized to have a

*Free, E. E., "The Movement of Soil Material by the Wind," Bul. 68, Bureau of Soils, U. S. Dept. of Agriculture, pp. 272, 1911.

large influence on its chemical and physical properties. The mineral character of the rock and the extent of decay determines the texture of the soil. The composition of the rock influences both the composition and texture of the soil in a distinctive way. The same rock may be transformed into soil by several agencies and again the same agency may act on several kinds of rock. The product is likely to be equally diverse in its capacity to support plants. A large variety of rocks might be recognized as influencing the character of soils. The fact that soil has usually been derived from quite a variety of rocks, makes it necessary to keep the divisions here as broad as possible, since only such can be recognized with any degree of accuracy. These are rather large groups and in practise special distinctions are likely to be made on this basis. The primary groups to be recognized may be mentioned as acid and basic rocks of igneous origin, and with these the gneisses, schists and similar secondary rocks are likely to be included; shale and slate, sandstone and quartzite, limestone and marble. Plant remains constitute a separate and distinct class of material from which soil may be formed and the proportion of these which enters into any given formation may give distinctive character.

Often the mingling of material from several kinds of rock may impart peculiar character to the soils of a drainage system or a lobe of glacial ice. The red alluvial soils of the Red River drainage system owe their character largely to the red Permian formations of Oklahoma and Texas. The glacial soils of west central New York are largely dependent for their character upon the several shale, limestone and sandstone rock formations crossed by the ice in reaching that position. The line of movement of the material with reference to the gen-

eral rock structure will largely determine the relation of the soil to any particular rock formation.

V. *The Series*.—The soil series is the most complex of the separations made in practise. Unlike the others, it does not rest upon a single character. Its separation requires the employment of a group of correlated characters. These are more intimate in their nature, more concerned with the material itself than the bases of the larger separations. Having applied those, the final grouping of types or units is determined first of all by

(a) *Color*.—Color as a physical property is not of great importance, but when considered in connection with the properties which are correlated with color it is of the greatest significance. Color is usually indicative of the proportion of organic matter, of the drainage, of the state of oxidation, of the proportion of lime carbonate and to a degree of the mineral composition of the soil.

(b) *Organic Matter*.—The proportion of organic matter is suggestive of the nitrogen content of the soil. It has a large influence on the availability of the mineral particles. It is indicative of the natural drainage, of the proportion of lime carbonate and of the activity and type of micro-organisms.

(c) *Lime Carbonate*.—The presence of a fair amount of this constituent has been pretty generally recognized as essential to a fertile soil.

(d) *The Total Plant Food Content of the Soil*.—While the average soil contains a relatively large quantity of the mineral plant food constituents, soils which are decidedly deficient in some one or more of these are sufficiently abundant to warrant the special consideration of this property. It does not necessarily involve general chemical analysis and may often be in-

ferred from other properties. The solubility of the soil constituents, while seldom a distinctive series basis of separation, is often indicative of other characteristics of the soil and as alkali, especially, of the type of climate. These several elements will seldom, if ever, have equal value in deciding a separation. They can not well be applied independently in general field work. In some cases one, as color, may be dominant; in another drainage, and in still other separations it may be the lime content which will determine the grouping.

If one consider all soil series together without reference to their grouping according to the broader bases of classification, such as formation, etc., it will generally be observed that soil series are chiefly distinguished by chemical differences, that is, differences in composition and chemical form. Organic matter is suggestive of the nitrogen content, solubility, etc. The presence of lime is a matter of composition. Differences in rock material mean certain differences in composition. On the other hand, the last or unit separation of soils is based chiefly on physical properties—texture and structure. The series includes all material having the same characteristics, but varying in texture from the coarsest to the finest.

VI. *The Type. Texture and Structure*.—The fineness of the material of which a soil is composed is the most broadly influential of the physical properties of a soil. Through its influence on porosity, moisture relations, aeration, temperature, tillage properties, etc., it is probably the most dominant in deciding crop adaptation and agricultural value. The more distinct textures of clay, loam, silt and sand are generally recognized. These rest upon the proportion of particles of different sizes and a great variety of proportions may be recognized and given names. These are

being multiplied. A question requiring further consideration is the number of sizes of particles—separates—to be recognized and the limits of these. Several systems of groupings are now in use.¹⁰ The finer the particles the greater is the influence of a given mass of them upon the character of the soil. Many more divisions should, therefore, be made in the fine material than in the coarse material. It is an open question whether, as survey work has been done in the United States, sufficient divisions have been made below the sand classes. Undoubtedly field separation of materials by hand examination is not likely to be more refined than is possible with the divisions now generally made. However, finer distinctions in the mechanical analysis of material smaller than 0.005 mm. may explain some variations in types of soil not otherwise recognized and these form the basis for more detailed study of individual types.

The structure of a soil as determined by the order of stratification and the thickness of the layers may also be the basis of type separation. This is independent of general structural differences due to the general mode of formation and the characters of the rock.

The soil type is the unit for soil study and should be as nearly alike in all parts as is possible. It is the most important grouping of material primarily because it does represent the chief physical differences in soils. The next most important grouping is the soil series and these two will be most generally identified with particular crop and agricultural interests in practise. This does not minimize the value of the larger separations, which, as has been suggested, are essential to reasonable accuracy in these last two groups.

¹⁰ Briggs, L. J., et al., "The Mechanical Analysis of Soils," Bul. 24, Bureau of Soils, U. S. Dept. of Agr., 1904.

Of course the final test of a survey must be in the field man who applies these principles to a particular set of conditions. Owing to the intimate overlapping of several fields of natural science in this work it is evident that he should be a man of broad training, including especially geology and the principles of soil fertility, and he should have keen power of observation and correlation. Scarcely any experience or training which the field man may possess but finds use in the ideal soil-survey man.

ELMER O. FIPPIN

CORNELL UNIVERSITY

THE BRITISH ASSOCIATION

A PRELIMINARY program has been issued for this year's meeting of the British Association, which, as already announced, is to take place at Dundee from September 4 to 11. The meeting will be the eighty-second of the series, the twelfth in Scotland, and the second in Dundee, the association having previously met in that city in 1867.

The opening meeting will be held in the Kinnaird Hall on Wednesday evening, September 4, when Professor E. A. Schäfer, F.R.S., will assume the presidency and deliver his inaugural address. In the same hall the first evening discourse will be delivered on Friday, September 6, by Professor W. H. Bragg, F.R.S., on "Radiations Old and New," and the second on Monday, September 9, by Professor A. Keith, on "The Antiquity of Man." The reception room and offices will be established in the Albert Institute, and a considerable proportion of the sections will have their meeting-rooms in the University College.

Arrangements have been made with the railway companies for the issue to members of return tickets at reduced fares, available for the period of the meeting and eight days after, and excursions during and after the meeting, for the purposes of scientific field-work, are expected to prove particularly important this year. The famous Alpine flora of Clova and Glenesk, the fossil fish beds of Dura Den, and the geology of the Stonehaven region and of the Western Highlands

are among the objects of contemplated visits. The President will have the assistance of a body of vice-presidents representative of the administrative, educational, ecclesiastical and commercial interests of Dundee and its neighborhood, headed by the Lord Provost of the city, Mr. James Urquhart, LL.D., and in the notice of entertainments to be arranged in connection with the meeting the names of the Earls of Moray, Strathmore and Camperdown and of Lord Kinnaird appear as hosts.

PENSIONS AT THE UNIVERSITY OF CHICAGO

As has already been noted in *SCIENCE* the trustees of the University of Chicago have arranged a system of retiring allowances, and for this purpose propose to set aside a sum not less than \$2,000,000. The trustees do not reserve the power of altering the statute to the disadvantage of those in the service of the university at the time it was enacted. The full statute reads as follows:

1. Any person in the service of the university and sixty-five years of age who holds the position of president of the university, director or associate director of the university libraries, or university examiner, and who has been for a period of fifteen years in the service of the university, in a rank not lower than assistant professor; and any person in the service of the university and sixty-five years of age, who has been, for a period of fifteen years in a rank not lower than assistant professor, a member of the teaching staff of the graduate schools of arts, literature and science, the graduate divinity school, the law school, or the colleges, may retire from active service, or be retired by the board of trustees on an annual allowance to be computed as follows:

(a) For fifteen years' service, 40 per cent. of the average annual salary received during the five years immediately preceding the time of retirement.

(b) For each year of service beyond fifteen years, 2 per cent. of the said average annual salary.

But no annual allowance shall exceed 60 per cent. of the said average annual salary, nor shall it exceed \$3,000.

A person between sixty-five and seventy years of age, eligible to a retiring allowance, may retire, or may be retired by the board of trustees; at the

age of seventy years he shall retire, unless the board of trustees specially continues his service.

2. The widow of any person in receipt of, or eligible to, a retiring allowance at the time of his death, shall be entitled to one half of the amount of his allowance during the period of her widowhood, provided she was his wife at the time of his retirement and had been his wife for not less than ten years before his death.

3. No right or claim under this statute shall vest in, or accrue to, any person until a retiring allowance shall become due and payable under and in accordance with it; and the exercise of the right or power of the board of trustees to terminate the service, or reduce the salary, of any person shall not give to such person any claim or cause of action hereunder against the university.

4. The board of trustees reserves the right to suspend the retiring allowance of any person, who, while in receipt of such allowance, accepts an appointment on the staff of any other institution of learning.

5. The obligation of the university to pay retiring allowances shall be neither greater nor less than its obligation to pay salaries to persons in active service, so that if misfortune should compel a percentage reduction of salaries, retiring allowances may be reduced in the same proportion.

6. Nothing in this statute shall preclude the board from granting other retiring allowances, or allowances on account of disability to officers of administration or instruction, or their widows, where the term and character of service, or the special circumstances of the case make the same appropriate, or from adding a term of years to the actual years of service of a person who enters the service of the university as an associate professor or of higher rank.

7. The board of trustees retains the power to alter this statute, but the alteration shall not have any effect as to persons of the class or rank mentioned in Art. 1, at the time of such alteration.

SCIENTIFIC NOTES AND NEWS

MRS. MARY MAURY WORTH, of Richmond, Va., and other descendants of Matthew Fontaine Maury, the eminent hydrographer, have presented to the United States through President Taft the Maury medals, commissions and correspondence.

DR. KARL CHUN, professor of zoology at Leipzig, has been awarded by the University

of Göttingen the prize of the Otto Vahlbruch foundation, of the value of \$3,000.

DR. PIETRO ALBERTONI, professor of physiology in the University of Bologna, has been elected a member of the Italian senate.

DR. A. HRDLÍČKA, of the U. S. National Museum, has been named a corresponding member of the Société d'Anthropologie de Bruxelles, Belgium.

PROFESSOR FÜRBERGER, the director of the anatomical institute at Heidelberg, retires at the close of the summer semester and is succeeded by Professor Braus.

AN expedition for the study of malaria from the department of tropical medicine and hygiene of Tulane University, under the direction of Dr. Charles Cassidy Bass, sailed from New Orleans on April 20 for Central America.

DR. MARCUS BENJAMIN has just been informed that his valuable collection of the portraits and autograph letters of the presidents of the American Association for the Advancement of Science received the award "diploma d'honneur" from the exposition that was held in Turin, Italy, last summer.

DR. AMOS W. PETERS, of the Carnegie Food Laboratory in Boston, has been appointed biochemist in the research department of the Training School for Feeble Minded Children, at Vineland, N. J. So far as is known this is the first appointment of the kind ever made. Five years ago, the Vineland Training School opened a department of research for the scientific study of mental defectiveness of which Dr. Henry H. Goddard was made director. Studies in growth, heredity, classification of defectives, the measurement of intelligence have been carried on and now the work is being extended in other lines. Dr. Peters has worked in zoology and biochemistry at the University of Illinois and later at the Harvard Medical School with Dr. Otto Folin. He will carry on studies in metabolism and brain chemistry. He will begin the new work about July 1.

AMONG recent lectures of scientific interest at the University of Illinois are the follow-

ing: three lectures on "Heredity," by Professor W. E. Castle, of Harvard University; "The Paleozoic History of Illinois," by Dr. T. E. Savage, of the Geological Department of the university; "Foreign Students and Student Life at the University of Berlin," by Dr. Wilhelm Paszowski, of the University of Berlin; "Morals and Moral Ideals of the Japanese," by Professor Inaze Nitobe; "Some Methods that have been tried in University Business Organization," by Dr. H. C. Bumpus, business manager of the University of Wisconsin; "European Bridges," by Professor F. O. Dufour, of the department of civil engineering.

A JOINT meeting of the Columbus Section of the American Chemical Society with the Ohio State University Sigma Xi Society was held on April 17, when the address of the evening was delivered by Professor R. A. Millikan, of the University of Chicago, on "New Proof of the Kinetic Theory of Matter and of the Atomic Theory of Electricity."

BEFORE the Society of Sigma Xi of Columbia University, Professor Henry E. Crampton gave on May 2 an illustrated lecture on "A Zoologist's Trip to South America."

ASSOCIATE PROFESSOR JAMES R. WITHEROW, of the Ohio State University chemical department, recently delivered a lecture before the Kenyon College Chapter of the Phi Beta Kappa, on the "Destructive Distillation of Heartwood."

ON returning to Europe in September Captain Raold Amundsen will make his first address before the Norwegian Royal Geographical Society in Christiania. A few days later he will lecture before the Royal Geographical Society in Berlin, then in other cities in Germany, Austria and Switzerland. On November 18 he will address the Royal Geographical Society, London.

DR. HOWARD T. BARNES, MacDonald professor of physics in McGill University, will lecture before the Royal Institution of Great Britain on May 31, on Icebergs and their Location in Navigation.

THE Rev. George William Knox, professor of philosophy and the history of religion in the Union Theological Seminary, died on April 25, at the age of fifty-nine years.

PROFESSOR CHARLES HENRY CHANDLER, emeritus professor of mathematics at Ripon College, died, on March 29, from heart failure, at the age of seventy-one years. He graduated from Dartmouth College in 1868, taught at Antioch College from 1871 to 1881, and at Ripon College from 1881 until his retirement on the Carnegie Foundation in 1906. He was for many years a fellow of the American Association for the Advancement of Science.

THE death has occurred of Mrs. Margaret E. Stinson, who for forty-six years was connected with the Massachusetts Institute of Technology, latterly in the care of the chemical apparatus. During her long connection with the institute she assisted and befriended many of the students.

DR. WILLIAM OGLE, distinguished for his contributions to vital statistics, died on April 12 at the age of eighty-four years.

THE nineteenth summer meeting of the American Mathematical Society will be held at the University of Pennsylvania on Tuesday and Wednesday, September 10-11, 1912.

THE Society of American Bacteriologists will hold its annual meeting in New York City at the close of this year.

THE next annual meeting of the Biochemical Association will be held at the College of Physicians and Surgeons, Columbia University, on Monday evening, June 3. Besides the usual business meeting there will be a scientific program consisting of the presentation of reports of recent researches by members of the association. This scientific session will be the first of an annual series of similar meetings. Abstracts of the reports will be published collectively in the June issue of the *Biochemical Bulletin*.

MR. J. B. TYRRELL, the geologist and mining engineer, is to lead the Ontario government expedition into the north to locate the five-mile strip which the province is to receive

from the Dominion. Although the route has not been settled, the party will probably proceed first to Winnipeg about the end of May, and thence to Lake Winnipeg to Port Nelson, much of the journey by canoe. At the mouth of the Nelson River, some time will be spent in locating the ten-mile strip which Ontario will have as a terminus for the Temiskaming and Northern Ontario Railway, should it be decided to extend the line there. The party will then head for the south, and a larger part of the five months will be taken up in exploring the 50-mile stretch along Hudson Bay, anywhere in which the government has a right to choose its five-mile strip.

PROFESSOR C. H. EIGENMANN, of the Indiana University and the Carnegie Museum, after a successful exploring trip on the rivers of Colombia, returned by the *Alemanía* on April 15. The main object of this expedition was to secure a series of the fishes of Colombia. After collecting in the lower courses of the Magdalena River, he ascended that river to an elevation of one thousand feet at Girardot. From here a side trip was made to Bogota. After returning to Girardot, he went by pack-train, *via* Ibagué, Cartago, Cali to Caldas on the Pacific slope. From Caldas he went by train to Buenaventura on the Pacific Coast. In this trip collections were made in all the streams crossed and especially in the Rio Dagua, flowing into the Pacific from an elevation of 5,000 feet to tide water. From Buenaventura he went up the San Juan, first by steamer and later by dug-out canoe with Indians to Istmina. From Istmina the divide between the Pacific and Atlantic slopes was again crossed by horse to Tambo. From Tambo, at first small canoes and later one larger canoe took him and his effects on the San Pablo and Rio Quibdo to Quibdo. As the navigation of all of these streams was very irregular on account of the unusually dry season, special arrangements were made to take him from Quibdo to Rio Sucio where, on account of a scare of pirates, the regular steamer from Cartagena was delayed awaiting the arrival of a company of soldiers from

Cartagena. This brought him to Cartagena on April 2, only three days beyond the date on which he hoped to sail.

On April 20 Governor Dix signed a bill appropriating \$500,000 for the rehabilitation of the New York State Library. This makes a total of \$622,000 appropriated for this purpose since the destruction of the library by fire in March, 1911. Beyond the fundamental general reference material, the State Library will specialize in science only so far as may be necessary to serve such agencies or departments of the state government as are doing scientific work. Good working collections will be made in geology, zoology, entomology, botany, with more particular attention to the economic phases of these subjects, and in chemistry as related to agriculture, the arts and commerce. The fact that the New York State Museum is administratively connected with the State Library will mean that in the subjects falling within the scope of the museum's work special attention will be given to the establishing of a notable collection of books.

THE Smoot bill to consolidate all national parks and monuments under one Bureau of National Parks, has been reported favorably by the Senate Committee on Public Lands. The measure has the endorsement of the Interior Department and the American Civic Federation.

THE University of California will establish a temporary outpost this summer in the Yosemite Valley. At the conclusion of the summer session (which extends from June 24 to August 4) the summer students of botany and zoology will go to the Yosemite for two weeks. The botanical students will put into practise the training received at Berkeley, by field studies on the classification and zonal distribution of the flowering plants and ferns in that portion of the Sierra Nevada. Meanwhile those who have had the summer session courses in zoology will study the habits and characteristics and ways of life of the mountain birds and mammals of the Yosemite region. For five weeks during the summer a

party of summer session students will be encamped south and east of Mount Diablo, engaged in collecting fossils, identifying extinct animals of which they are the remains, and mapping the faunal zones which record the changes of species over periods of uncounted hundreds of thousands of years. Still another summer outpost of the university will be the Summer School of Surveying, at Camp California, near Swanton in Santa Cruz County. Here some 200 men will be learning how to make maps, survey lands, run railroads and canals and lay out irrigation and drainage systems.

THE *Journal* of the American Medical Association states that the originator and president of the recent international hygiene exposition at Dresden, Dr. Lingner, has petitioned the local authorities to establish a national museum of hygiene in Dresden. It is contemplated to use the hall, "Man" (*Der Mensch*), which proved the greatest attraction for visitors to the exposition, as the nucleus of the museum. The museum is to be designed to realize the important principle that every one shall gain by direct inspection the knowledge which will fit him for a sanitary and intelligent conduct of his life. For the completion of this self-instruction, popular weekly lectures are to be held, which will gradually cover the entire field for the care of health. In addition, the management of the museum shall provide scientific lectures and demonstrations for professional people, that is, for physicians, officials, engineers and the leaders of industry. An academy of scientific character is also proposed to supplement the museum. Lingner will present to the museum the objects exhibited at the exposition, which represent a value of \$250,000. The land, which is reckoned at about 6,000 square meters, is to be donated by the city of Dresden. The expense of building and furnishing are reckoned at about \$875,000. The expense of building will be defrayed first out of the surplus from the international hygiene exposition, amounting to \$250,000, while the government of the province (Saxony) will give the rest. The annual expenses are estimated

at about \$62,500. Of this, the city of Dresden will furnish \$37,500; the special income of the museum from entrance money and fees for attendance at lectures, etc., is estimated at \$20,000. The rest, it is hoped, will be supplied by gifts. The museum is to include three chief divisions, "Der Mensch," the historical division and the ethnologic division.

UNIVERSITY AND EDUCATIONAL NEWS

NEARLY two hundred thousand dollars have been subscribed to the equipment fund in the past two weeks, according to the announcement of the Alumni Fund Committee of the Massachusetts Institute of Technology.

THE Sheffield Scientific School of Yale University has received from Mr. Murray Guggenheim, of New York City, \$20,000 as a nucleus of a fund for additional instruction and equipment in the branches of mining and metallurgy.

By act of legislature of the state of Pennsylvania, dated April 20, a charter of incorporation, with the power to grant degrees, was given to the Carnegie Technical Schools, and the name of the institution is changed to the Carnegie Institute of Technology.

WORK has been commenced upon the construction of the new Ceramics and Mining Engineering Laboratories of the University of Illinois. These buildings are to form a part of the group of engineering buildings to be located upon ground east of Mathews Avenue, which has recently been acquired by the university. The contracts for the new Transportation Building and the Locomotive Testing Laboratory will soon be let.

PROFESSOR FILIBERT ROTH, head of the forestry department of the University of Michigan, who recently accepted the chair of forestry at Cornell, has reconsidered his decision and will remain at Michigan where the regents have agreed to provide additional facilities for the forestry school.

PROFESSOR FREDERICK E. BOLTON, professor of education and director of the school of education in the State University of Iowa, has accepted a call to become head of the depart-

ment of education in the State University of Washington at Seattle, and will begin his work at that place in September.

DR. ROBERT CHAMBERS, JR., has accepted an appointment as assistant professor of histology and embryology in the University of Cincinnati. Dr. Chambers is on the teaching staff of the Marine Biological Laboratory, Woods Hole, Mass., and has held the position of lecturer in the University of Toronto for the last three years. He now has a fellowship in Professor E. B. Wilson's department.

DISCUSSION AND CORRESPONDENCE

THE NAME AND BRAIN OF THE GAR

TO THE EDITOR OF SCIENCE: From my former pupil and assistant, Asa C. Chandler, A.B., now on the staff of the University of California, I have recently received a copy of his paper, "On a Lymphoid Structure Lying Over the Myelencephalon of *Lepisosteus*," constituting No. 2 of Vol. 9 of the "Publications in Zoology" edited by Professors Ritter and Kofoed of that institution. Every such contribution to the knowledge of this genus is to be welcomed as helping to remove the "reproach to the comparative anatomists of this country that the brain of this [almost] exclusively American form should not have been fully elucidated."¹ Material and literature for the profitable discussion of the structure and homology of the newly described organ are now inaccessible; but a careful

¹The sentence here quoted is from my review of Wiedersheim's "Comparative Anatomy of Vertebrates," SCIENCE, N. S., Vol. 27, May 8, 1908, under the caption, Fig. 159. The bracketed word is introduced in qualification of the too sweeping statement as to the distribution of the genus; according to Jordan and Evermann it is represented in China by a single species, *L. sinensis*. Never having seen an example of this species, or even a picture or description of it, I had forgotten its existence not only when the sentence quoted was written, but also when trying to enumerate my errors ("Some Mistakes of the Writer and Others," etc., SCIENCE, N. S., Vol. 34, July 21, 1911). Are the other readers of this journal equally ignorant, or forgetful, or simply indifferent, or needlessly sparing of my feelings?

reading of the paper has led me to make some notes which I should submit to the writer were we still associated and which I hope will not be without interest and profit to others.

1. *The Generic Name of the "Gar."*—Mr. Chandler and the editors adopt *Lepisosteus* as introduced by Lacépède in 1803 rather than *Lepidosteus* as corrected by the elder Agassiz and—till lately—almost universally employed. With all admiration for President Jordan (another former pupil who, I think, suggested or at least sanctioned the change), I feel that this is too rigid an application of the "priority rule." Had an ignorant or heedless person first christened the "duck-bill" as *Ornisorhynchus* should we have perpetuated a blunder that would offend all scholars? I doubt it. Conceding, however, that in this matter each has a right to his own opinion and usage, I protest against the change in the title of my paper, "On the Brains of *Amia*," etc.,¹ where the original *Lepidosteus* is converted into *Lepisosteus*. I hold that the latter form has no etymologic standing, and—excepting in quotation—would no more use it than a profane expletive.

In this connection it may be properly mentioned that the specific name of the "alligator gar" is not *tristachus*, as used by Mr. Chandler on p. 87, but *tristachus*, from *στρίχτος*.

2. *The Contour and Constitution of the Gar's Brain.*—The dorsal aspect is represented in the text-figure A. It is very unlike the corresponding figure of Balfour and Parker as reproduced by Wiedersheim. Although I have exposed several gar brains, unable now to refer to them, I will not undertake to say which of these figures is the more nearly correct; possibly difference of species or age may account for some discrepancies, certainly not for all. Chandler's figure contains no indication of the thalamic region (diencephalon or "thalamencephalon") or explanation of its omission. The outline is represented by a continuous line; it should be interrupted at the place of emergence of the olfactory nerves even if the nerves themselves are omitted.

¹ Amer. Asso. Adv. Sci., Proc., 1875.

3. *The Names of the Parts.*—Why should the two cephalic ("anterior") pairs of lobes be designated as "anterior" and "posterior lobes of the cerebrum" when there can be no doubt that the first pair are the hollow olfactory bulbs and the second the solid striata (unfortunately called "prothalami" by me in 1875)? And since the, so to speak, "specific" names of these two parts, of the "optic lobes," and of the "trilobed cerebellum," were deemed adequate for their designation, and since the segmental constitution and names were in no way concerned in the general treatment of the subject, why should the region supporting the newly described lymphoid structure be singled out for the application of the ponderous title, "myelencephalon" when "oblongata" or "medulla oblongata" would have sufficed? "Oblongatal gland" would be unobjectionable. Excepting, perhaps, his own coinage, "Isthmus rhombencephali," for a region since commonly admitted to be non-existent or negligible, *myelencephalon* is one of the most objectionable components of the neurologic nomenclature selected by the late Professor His, adopted by the Anatomische Gesellschaft, and blindly, hastily or slavishly employed by many in this country. Its only logical justification would be the adoption of Owen's "myelon" in place of "medulla spinalis." Even if myelencephalon is preferred, should not "metencephalon" have been added as a synonym? It is a more appropriate equivalent of Von Baer's "Nachhirn"; it is quite as familiar to most anatomists; it was preferred by the majority of the committee on nomenclature of the Association of American Anatomists in 1897; and, as has been pointed out by me on several occasions, the prefix lends itself readily to useful and euphonious compounds, *metacele*, *metaplexus*, *metatela* and *metapore* ("Foramen of Magendie"). These considerations render me hopeful that when there comes a subsidence of "Hisolatry" and of the prevailing obsession of most American anatomists for ideas and words "made in Germany," the last encephalic segment will be known as *metencephalon* and the last but one as *epencephalon*.

To offset in some measure the foregoing criticisms of the terminology of Mr. Chandler's paper let me commend his use of pial, dorsal, caudad and cephalad.

BURT G. WILDER

A FISTULA IN THE DOGFISH

IN a shipment of dogfish pups (*Mustelus canis*) sent from Woods Hole to the Biological Laboratory of New York University during the summer of 1910, there was a specimen about 20 inches long with a coelomic fistula which had been closed in a curious manner. The opening was on the ventral surface, just posterior to the left pectoral fin. Externally it was not conspicuous, the tissue of the oval scar being much the same color as the surrounding skin, although evidently of a somewhat different texture.

On laying open the body cavity it was found that the fistula had been plugged by a growth from the left lobe of the liver, which had filled the wound completely without adhering to the structure of the body wall. The edge of the cicatrice, after the liver had been drawn away intact, was smooth and thoroughly healed.

ROBERT CUSHMAN MURPHY

MUSEUM OF THE BROOKLYN INSTITUTE

NOTE ON "SOME EARLY PHYSIOGRAPHIC INFERENCES"

AMONG the interesting physiographic comments quoted from early writers by Dr. Emerson on page 374 of SCIENCE for March 4, the one by James Hall is evidently misinterpreted. The quotation is as follows:

About midway between St. Louis and the mouth of the Ohio, masses of limestone rock are seen on either side, which, though now unconnected, have the appearance of once having formed a continuous ridge crossing the river in an oblique direction.

This is supposed by Emerson to refer to the bluffs bordering the new trough of the Mississippi River near Thebes, Ill., where it leaves its old valley and crosses into another formerly occupied by the Ohio River. It seems practically certain, however, that Hall had in

mind a conspicuous ridge of limestone beds dipping steeply northeastward, which appears on the west bank of the Mississippi in Perry county, Mo. Just below Wittenberg, this ridge has evidently been obliquely intersected by the river, the obvious southeastward continuation in a direct line appearing on the east bank in the picturesque series of isolated rock masses known locally as the Devil's Bakeoven and Devil's Backbone; the latter ending abruptly at the town of Grand Tower, Ill. This is about three fifths of the distance from St. Louis to the Ohio, while the Thebes cut is only a short distance above the mouth of the Ohio; and at the cut neither the rock masses nor the oblique direction are especially evident.

CHARLES A. HART

ILLINOIS STATE LABORATORY
OF NATURAL HISTORY

SCIENTIFIC BOOKS

The Mechanical Factors of Digestion. By WALTER B. CANNON, A.M., M.D., George Higginson Professor of Physiology, Harvard University. Illustrated. London, Edward Arnold; New York, Longmans, Green and Co. 1911. Pp. 227.

The motor activities of the muscle tube which forms the digestive system has long been a favorite subject of investigation, and a considerable mass of valuable information is at our disposal. But this evidence often shows a marked lack of harmony, even though the observations were made upon the same organ in the same animal. The fault, however, lay not so much with the experimenters, as with the methods employed; there was no single procedure which was applicable for the study of the entire gastro-intestinal canal without grave operative interferences, and these interferences often altered or even abolished the very function which was to be investigated. It was therefore natural that varying interpretations and consequent confusion should arise. In 1896, a method was developed by means of which the motor functions of the entire digestive tube, from pharynx to rectum, could be observed without

any operation whatsoever; or the effects of operations (resection of nerves, portions of the gut, etc.) could be studied after the animal had fully recovered. Cannon achieved this result by means of the X-ray. This method depends on the fact that food mixed with a salt of bismuth (subnitrate or oxychloride; an iron salt has also been used lately) becomes opaque to the X-ray. If the subject under investigation, man, dog, cat or other animal, ingests this bismuth paste, the bolus may be observed on the fluorescent screen, for the bismuth mass blocks the X-rays and betrays its presence to the observer by a vibrating shadow on this screen. The progress and change in shape of this shadow disclose to the eye of the expert observer the character of the muscular activity of the digestive system.

Besides originating and perfecting this method Cannon has also been the foremost modern investigator of gastro-intestinal motility. The experimental results with which he enriched physiology during the last fourteen years have, however, only recently been collected by him in a monograph, and this monograph is the first authoritative attempt to give a complete, critical study of motor digestive activities as a whole, using as a guide the results gained by his new method. Although Cannon's work forms by far the largest part of our modern knowledge of the motor activities of the gut, his monograph is by no means a one-sided presentation of the results obtained by his laboratory; other important work, gained by various experimental methods, is critically considered and brought into relation with the direct testimony which the X-ray affords.

The entire subject matter is considered by Cannon in sixteen concise chapters, and the chapter headings will indicate to the reader how completely the field has been covered. I., General Features of the Movements of the Alimentary Canal, and Methods of Investigation; II., The Movements of Mastication and Deglutition; III., The Nervous Control of Deglutition; IV., Conditions Affecting the Activities of the Cardia; V., The Movements of the Stomach; VI., The Effect of Stomach

Movements on the Contents; VII., The Stomach Movements in Relation to Salivary Digestion and Gastro-enterostomy; VIII., The Passage of Different Foodstuffs from the Stomach; IX., The Acid Control of the Pylorus; X., The Correlating Functions of the Pylorus, and some Conditions Affecting It; XI., The Movements of the Small Intestine; XII., The Movements of the Large Intestine; XIII., Auscultation of Gastro-intestinal Sounds; XIV., The Intrinsic Innervation of the Gastro-intestinal Tract; XV., The Extrinsic Innervation of the Gastro-intestinal Tract; XVI., Depressive Nervous Influences Affecting Gastro-intestinal Movements. At the end of each chapter a complete list of the more important literature references is given, and this list will be a great convenience for many research workers.

While these chapter-headings show the scope of the book, they give no indication of their interesting, and attractively presented, contents. Although it is not possible here to discuss all the valuable and interesting sections of the book, and they will be found in every chapter, attention may be called to Cannon's theory of the acid control of the pylorus. The pylorus, a sphincter muscle which guards the opening of the stomach leading to the intestine, regulates the passage of the food into the duodenum (upper part of the small intestine). Depending upon the character and state of the food in the stomach, this gate-keeper feeds at intervals a spurt of food into the gut. By what mechanism is this accomplished? How can this ring of muscle-fibers differentiate, for example, between carbohydrates, which are permitted to leave quickly, and proteids, which remain for a considerable period of time in the stomach?

This remarkable behavior of the pylorus was first explained satisfactorily by Cannon, and his theory, in brief, is as follows: Free acid above the sphincter causes a relaxation of the muscle ring and a peristaltic wave is thus able to discharge a quantity of chyme into the duodenum. But as soon as the chyme reaches the duodenum, its acidity produces a closure of the pylorus. The acidity of the

chyme, however, is soon neutralized by the alkaline bile and pancreatic juices, and then the free acid in the stomach produces again an inhibition of the sphincter tonus and another quantity of chyme is driven out. This hypothesis has been tested by Cannon in numerous ways. He has shown, for example, that anything which delays the appearance of free acid delays the onset of the discharge from the stomach; that hastening the appearance of free acid hastens the time of discharge; and by means of a fistula, he was able to observe that the appearance of free acid closely precedes the first gastric discharge into the duodenum. In addition, Cannon showed that free acid causes opening of the pylorus in the *excised* stomach of a cat, thus proving that the control of the pylorus is independent of the central nervous system and resides probably in the local nerve plexus. Free acid, therefore, above the gastric sphincter causes it to relax, and this explains why carbohydrates leave the stomach much earlier than proteids, for both these food-classes stimulate the secretion of gastric juice, as Pavlov has shown, but the proteids unite with the acid as it is produced, forming acid albumen; there is thus no free acid available for a considerable period of time, and, as shown above, free acid is necessary to cause a relaxation of the pylorus. There is no such difficulty with carbohydrates; as soon as the free acid appears the pylorus relaxes, and the crackers, potato-mush, or whatever carbohydrate was fed, is at once transferred to the gut by the peristaltic waves of the stomach.

The evidence that free acid *below* the sphincter, in the duodenum, causes closure of the pylorus, is just as conclusive, for various investigators had shown that acid in the duodenum slows the output of chyme from the stomach, and this must be due to an effect on the pylorus, for Cannon demonstrated that gastric peristalsis was not stopped during this condition. Another support was furnished by the observation of Pavlov that acid solutions leave the stomach much more slowly in dogs with a pancreatic fistula than in normal animals. This is easily explained by the

fact that absence of the alkaline pancreatic juice permits the chyme to remain acid in the duodenum for a longer period, and thus the stimulus which causes closure of the pylorus remains effective until the food material becomes neutral or alkaline. Cannon studied the effects of ligation of the larger pancreatic and bile ducts on the rate of discharge from the stomach and gives a chart which shows the marked delay caused by this interference. The stimulus which causes the closure of the pylorus is mediated through the myenteric nerve plexus, for after severance of the entire muscular coats of the duodenum just below the pylorus, Cannon found that the discharge of the stomach content was considerably more rapid than in normal animals: the acid chyme undoubtedly still produced its usual stimulus in the duodenum, but this stimulus could not reach its destination, the pyloric sphincter, because its path had been destroyed.

From the foregoing it will be seen that Cannon's theory seems adequately and simply to explain one of the most remarkable functions in the body, and it is of theoretical interest that the same agent may exert diametrically opposite effects, the sign of this effect being dependent upon the locus of the stimulation.

It may be said, in short, that this concise monograph by Professor Cannon gives a balanced and authoritative view of the present state of our knowledge regarding the motor mechanism of digestion under normal and experimentally modified conditions. In addition, the reader will find that the presentation is lucid and that dogmatic statements are absent.

ROCKEFELLER INSTITUTE

CHEMICAL TEXT-BOOKS

The Elements of Qualitative Chemical Analysis with Special Consideration of the Application of the Laws of Equilibrium and of the Modern Theories of Solution. By JULIUS STIEGLITZ, Professor of Chemistry in the University of Chicago. Parts I. and II. Fundamental Principles and their Ap-

plication. Parts III. and IV. Laboratory Manual. New York, The Century Co. 1911.

As the appearance of Ostwald's "Foundations of Analytical Chemistry" in 1894 showed the way by which it would be possible to transform analytical chemistry from a somewhat mechanical process to a scientific system based on definite laws, and as the investigations of A. A. Noyes and Bray furnished the facts necessary to enable one to select the methods most exact and rapid, so the appearance of this work has marked a milestone in the progress of the science of qualitative and quantitative analysis. In this work the author has collected and applied the observations and deductions which have resulted from the researches of the last score of years in the field of physical chemistry and has furnished a rational explanation for reactions which have hitherto been merely empirical. The work is divided into two parts, the theoretical and the applied. How inspiring it would be if a teacher could always start with a class already trained in physics and mathematics and, with more than the usual time at his disposal, use this method, knowing that he was turning out thinking chemists instead of mechanical analysts. Unfortunately in many cases neither the time nor the previous training of the students is such as will enable him to use this book to advantage, so far as the undergraduate student is concerned, but this is the fault, not of the book, but of conditions governing the methods of instruction and arrangement of courses in different institutions.

Part I. of Vol. I. contains a discussion of the fundamental principles which lie at the foundation of analyses, such as ionization, chemical equilibrium and the law of mass action, osmotic pressure, the colloidal condition and the conditions governing precipitation. All of these questions are discussed in a very clear manner with constant reference to examples in the way of reactions in qualitative analysis. In Part II. we find a general discussion of the methods used in testing for the metallic ions with a detailed statement of each step in the process, great emphasis being

placed on the reasons for each step and upon the bearing of the dissociation theory and the law of mass action upon the question under consideration. The theory of the separation of some of the metals by the precipitation with hydrogen sulphide and the theory of complex ions, as well as a discussion of the process of oxidation and reduction, the latter being regarded as involving essentially the loss or gain of electrons, are treated in a very thorough manner.

Although the views here expressed regarding oxidation and reduction may not be generally accepted the subject is admirably presented from the author's point of view.

In Vol. II. we find a discussion of the reactions of the individual metals and acids, especially those reactions which are made use of in qualitative analysis and a very full and clear course in systematic analysis. It would be very desirable if every student of chemistry could follow the course mapped out in this book and work out all the reactions according to the principles given in Vol. I.; but in many instances the time allotted to a course in qualitative analysis is too short to permit the use of such a detailed method. •

Every teacher of chemistry and every advanced student of chemistry should study carefully the material contained in this book.

To one who is or is to be a chemist its value can not be overestimated. To the beginner in qualitative analysis its thoroughness and scope should be an inspiration and lead to the very desirable conception of quantitative chemistry as much more than mechanical proficiency in manipulation.

A Handbook of Organic Analysis, Qualitative and Quantitative. By H. T. CLARKE, B.Sc. (Lond.), Lecturer on Stereochemistry in University College, London. With an introduction by J. NORMAN COLLIE. Longmans, Green & Co.

The Identification of Organic Compounds. By G. B. NEAVE, M.A., D.Sc. (St. Andrew), and I. M. HEILBRON, Ph.D. (Leipzig), F.I.C., Lecturers and Demonstrators, Department of Chemistry, Glasgow and West

of Scotland Technical College. New York, Van Nostrand Co. \$1.25 net.

In the first of these volumes efforts have been made to supply the organic chemist with a scheme of analysis and identification of the groups and compounds comparable to the scheme used for the identification of the metallic ions and acid groups. A system of this kind has been greatly needed; but, owing to the great similarity of organic compounds, so far as their constituents are concerned, and to the great diversity, so far as their behavior is concerned, up to the present has not been successfully developed.

By classifying the substances according to the elements they contain and by studying their action with water, alkali, acid, reducing agents, etc., the authors have been able to separate the substances generally met with into groups which in turn are subdivisions of classes. Having reached this point, the exact division to which the substance belongs can be determined by specific tests. Detailed methods are given for testing for the different classes of compounds, and a table of many of the more important substances with their physical and chemical properties serves as a valuable and handy reference. While this scheme of analysis may seem very crude as compared with the one we use in organic chemistry, it is a step in the right direction and worthy of careful study and testing.

The second of these books has the same object in view, but is on a less systematic and comprehensive scale. The general reactions seem too few and indefinite and the special reactions not specific enough to enable one to identify organic compounds by its aid unless considerable reference is made to other records.

Contemporary Chemistry. A Survey of the Present State, Methods and Tendencies of Chemical Science. By E. E. FOURNIER D'ALBE, B.Sc.; A.R.O.S.; M.R.I.A., author of "The Electron Theory, etc." New York, D. Van Nostrand Co. \$1.25 net.

The author has written a very interesting "birds-eye view of the whole field of modern

chemistry." While not intended as a history of chemistry, all the recent discoveries of importance have been included and their importance and relations to other phenomena have been pointed out. One who has worked in some other science than chemistry, as well as students of this subject, will find this book instructive and well worth reading.

Progressive Problems in General Chemistry.

By CHARLES BASKERVILLE, Ph.D., Professor of Chemistry, and W. L. ESTABROOKE, Ph.D., Instructor in Chemistry, College of the City of New York. Heath & Co. 1910.

The authors have brought together a large number of problems covering all the phases of chemical action. This book will furnish the teacher a mine of material from which he may select examples to meet the needs of the students as the different subjects are studied and so test their understanding of the principles involved. The solution of problems, such as these, is of special value in the early stages of the study of chemistry and especially with young students, as it demands the power of applying the facts and reasoning from them and not simply the ability to commit facts and reactions to memory. The value of this work might be increased by adding at the beginning of each subject a general statement as to the methods of solving the problems in this section and the principles involved for the aid of those who are not sufficiently familiar with the subject to work it out entirely independently.

J. E. GILPIN

THE JOHNS HOPKINS UNIVERSITY

Bibliography of Non-Euclidean Geometry, including the Theory of Parallels, the Foundations of Geometry, and Space of n Dimensions. By DUNCAN M. Y. SOMMERVILLE. London, Harrison and Sons. 1911. 8vo. Pp. xii + 403.

In these days, when a non-Newtonian mechanics, based on the principle of relativity, is forcing itself upon the attention of the scientific world, it is instructive to notice how valuable the non-Euclidean and n -dimensional

geometries have become, although it is only about forty years since they began to be appreciated thoroughly and studied systematically. The vast and increasing interest which these subjects have aroused is indicated by the fact that Sommerville's Bibliography contains the titles of about 2,300 works on non-Euclidean geometry, of which nearly 800 were published in the decade 1901-10, and 1,800 works on hyperspace, of which 700 belong to the same decade. Let us glance briefly at a few of the principal ways in which these sciences have shown themselves to be of importance, not only in mathematics, but also in the related domains of mechanics, logic, psychology and epistemology.

In the first place, a flood of light has been thrown on the epistemological problem of the nature of our spatial concepts. Kant's famous doctrine of the *a priori* synthetic nature of these concepts is seriously threatened by the modern geometry, and will require considerable modification, if it is not entirely rejected.

In the realm of psychology, also, these theories have a decided bearing on the distinction between the perceptual space of experience and observation and the conceptual idealized space of mathematics proper. The former space has a physiological basis, principally visual and tactual, and the theorems of its geometry can have only an approximate meaning. Now the striking fact is that this natural geometry of experience is much more nearly non-Euclidean than Euclidean. For instance, as Mach observes, the space of tactual perception, namely, the skin, corresponds roughly to a two-dimensional Riemannian space. Moreover, with all the refinements of astronomical observation the space of visual perception can obviously never be proved to be Euclidean.

The recent developments of deductive logic as typified by the symbolic logic of Peano and Bertrand Russell unquestionably owe much to non-Euclidean geometry; and they in turn have helped to make the foundations of geometry secure at last, after two thousand years of misplaced confidence in Euclid.

In the domain of mechanics, if in addition

to the three Cartesian coordinates of a moving particle we interpret the time as a fourth coordinate, we obtain a space of four dimensions, and thus establish a useful correspondence between three-dimensional kinetics and four-dimensional geometry. Now the remarkable thing about this correspondence is that whether the original kinetics is Newtonian or non-Newtonian, the corresponding geometry is in each case of a non-Euclidean type.

Perhaps the highest significance, however, of these seemingly pathological theories is due to the light which they shed on other, less suspicious branches of mathematics. For instance, the geometry of hyperspace provides a convenient language in which to express the theory of functions of several variables; and in particular the projective geometry of n -space is closely connected with the algebra of forms, or quantics, involving $n+1$ variables. Moreover, the point-geometry of 4-space helps us to understand the sphere-geometry of ordinary 3-space, because the spheres of 3-space form a four-dimensional aggregate.

Non-Euclidean geometry, also, derives its chief importance from its bearing on Euclidean geometry. It often discloses unsuspected bonds of relation between apparently disconnected Euclidean developments. It brings out the inner meaning of the process of building metric geometry on the basis of projective geometry. It gives a clear insight into the theory of surfaces of constant curvature. Of great value is the correspondence between the group of projective transformations which leave a quadric surface invariant and the group of non-Euclidean movements. Another correspondence of similar importance is that which exists between the group of conformal point-transformations of a Euclidean 3-space and the group of movements of a non-Euclidean 4-space.

Sommerville's Bibliography consists of three parts, a chronological catalogue, a subject index, and an author index. In the chronological catalogue the titles of the works published in each year are arranged alphabetically according to the authors. Later editions, translations and reviews are included.

In the subject index no titles are given, but references are given to the year and author, so that the corresponding title can be easily found in the chronological catalogue.

It is obvious that a scientific bibliography like this serves a very useful purpose to the student and investigator, especially when it is well arranged and possesses a high degree of completeness, as is the case here. With Sommerville's book at his command the worker in the field of non-Euclidean or n -dimensional geometry is unusually well equipped for referring quickly to the literature of his subject.

ARTHUR RANUM

CORNELL UNIVERSITY

Report on the Dune-Areas of New Zealand, their Geology, Botany and Reclamation.

By L. COCKAYNE, Ph.D., F.L.S., Department of Lands, New Zealand. Printed by John Mackay, government printer. 1911.

Because of extensive dune-areas and the impending danger to valuable lands from encroachment, the Dominion government commissioned Dr. Cockayne to conduct a careful investigation of the dune conditions in New Zealand and to embody certain recommendations as to the reclamation of the dune lands and the protection of threatened territory in a formal report. This report, which is an extension of the author's earlier researches, we now have from the government printer. The paper is divided into two parts; the first deals with the geology and botany of the dune-areas and the second with various methods of reclamation. In Part I. the geology of these dynamic habitats is very excellently handled under such subheads as: The Material of Dunes, Dune Building on the Coast, The Effect of Solid, Flexible and Inflexible Obstacles, and the Effect of Climate, General Topography of the Dune-areas in New Zealand, Movements of Dunes and Dune-sand. There are more than 300,000 acres of dune lands in North and South Islands, where occur chains of sandhills of irregular form, which are generally divided in places by basin-like hollows of greater or less extent. The wind plays a great part in constantly changing the form of

the dunes, the position of the hills, and in modifying the slope angles. Hills in all stages of growth and decay, and basins in the process of being hollowed out or being filled up appear on every side. The wider dune areas appear like seas of sand with the ridges as more or less stationary billows with their scanty vegetation.

Under "Botany" is treated such ecological matters as: Climatic Factors, Heat, Light, Moisture, Soil, Topography and Biotic Factors. The most characteristic plants with their growth-forms and adaptations are treated in considerable detail. The leading dune plants in New Zealand are: *Spinifex hirsutus* (Gramineæ); *Scirpus frondosus* (Cyperaceæ); *Euphorbia glauca* (Euphorbiaceæ); *Carex pumila* (Cyperaceæ); *Calyptegia Soldanella* (Convolvulaceæ); and *Arundo conspicua* (Gramineæ). These plants are distinguished as "sand-binders" in distinction to the following which are called "sand-collectors": *Caprosoma acerosa* (Rubiaceæ); *Pimelea arenaria* (Thymelæaceæ); *Cassinia leptophylla*, *C. fulvida*, *C. retorta* (Compositæ); *Festuca littoralis* (Gramineæ); *Calamagrostis Billardieri* (Gramineæ); and *Scirpus nodosus* (Cyperaceæ).

The commoner plant associations represented are: Sand-Grass Dunes, Pes Capræ Dunes, Shrub Dunes, Lakes and Swamps, Dry Hollows and Stony Plain. The various dune species are noted in tabular form with various ecological notes. This list includes 147 species of which 82 are endemic, 43 Australian and 15 South American. Fifty-one families and 104 genera are represented in this number.

The methods in vogue the world over for the artificial fixation of dunes are based upon those which nature herself uses and these are here enumerated as fifteen "fundamental principles" with which plant ecologists are more or less familiar. Marram-Grass, *Amphiphila arenaria*, and the Tree-Lupin, *Lupinus arboreus*, are noted as the best of the "sand fixers" for the region under consideration. The efficiency of these two species is compared in considerable detail. Under "Methods of Reclamation" the methods of preparing and

planting Marram-Grass and Tree-Lupin are discussed in detail and suggestions are included for the post-planting management of the plantations. The possibility of checking sand movement by means of sand-fences and protection belts is considerably elaborated. Protection belts are merely narrow bands of Marram set at the junction of the advancing sand and the invaded ground. Such a belt is efficient usually for only a few years unless it is constantly watched and repaired.

The report closes with a discussion of afforestation of the dunes, which method seems to the author to be the only means of establishing the desired static condition over the dune complex. Little tree-planting upon the dunes has been done in New Zealand under difficult conditions, but the method is strongly recommended. The more important trees and shrubs for dune afforestation in these islands are as follows: *Olearia Traversii*, *Pinus pinaster*, *Pinus halpensis*, *Araucaria excelsa*, *Cupressus macrocarpa*, *Pinus radiata* (most valuable), *Pinus muricata*, *Tamarix gallica*, *Lupinus arboreus*, *Acacia melanoxylon*, *Salix caspica*, *Populus deltoides*, *Populus balsamifera*, *Populus fastigiata* and *Alnus glutinosa*. Besides these species, all of them promising dune holders, *Pinus laricio*, *P. pinea*, *P. Coulteri* and *P. Strobus* grow "quite well" on the dunes of New Zealand. A final list of plants (over 200 species) suitable for dune cultivation in these islands contains useful information as to the habitat, growth-form, etc., for the various species, many of which are North American.

This very interesting and well-written paper is well illustrated by means of sixty-nine half-tones and three etchings, and includes a bibliography of sixty-six general works and seventy-three references to the literature of New Zealand Dunes.

RAYMOND J. POOL

THE UNIVERSITY OF NEBRASKA

Aerial Navigation. A Popular Treatise on the Growth of Air Craft and on Aeronautical Meteorology. By ALBERT F. ZAHM. New York, D. Appleton & Co. 1911. 8vo. Pp.

xvii + 497; 58 illustrations in text and 92 full page plates.

Amid the flood of ephemeral popular and pseudo-scientific books on this subject which have appeared in England and America during the past two years, here is one that rests on a solid foundation, fit to carry the superstructure of subsequent progress. The author, distinguished as a pioneer investigator of aerodynamics in America, has been intimately acquainted with Langley, Chanute and the Wrights, and a close student of aeronautics in Europe. Therefore Dr. Zahm is eminently qualified to write a book, which in character resembles the reviewer's earlier and smaller "Conquest of the Air," a revised edition of which Dr. Zahm's later and more detailed publication seems to render superfluous. However, the most recent achievements in aeronautics chronicled in any book are already antiquated and surpassed when presented to the reader and conclusions based thereon require corresponding modification.

Authors naturally give prominence to those subjects with which they are most familiar and, therefore, while the reviewer accorded first place to the Ocean of Air, Dr. Zahm puts Aeronautical Meteorology last, having compiled this section largely from other authors and thereby somewhat neglected its status in this country. The two preceding divisions of the book are: the Growth of Aerostation, in which both spherical and dirigible balloons are considered, and the Growth of Aviation, treating of early attempts to fly, the modern glider and the power aeroplane. An appendix contains technical papers and three letters of Benjamin Franklin, written from Paris in 1783 describing the first balloons, which are reprinted from "The Conquest of the Air." The author refrains from prophecies concerning future developments of craft either lighter or heavier than air, since progress in the art of aerial navigation has been so rapid as to baffle conjecture concerning their ultimate applications.

In conclusion, it may be said that the work can be recommended, to either the lay or scientific reader, as admirable in its material

and method of presentation. The numerous illustrations are wisely chosen and well rendered and the few errors noticed in the text are mostly typographical. A misleading misprint occurs in the statement that the first successful dirigible balloon in 1885 sailed from Calais to Paris and returned to its place of departure, which really was Chalais-Meudon, a suburb of Paris.

A. LAWRENCE ROTCH¹

BLUE HILL METEOROLOGICAL OBSERVATORY

SPECIAL ARTICLES

HEATING OF LOCAL AREAS OF GROUND IN CULEBRA CUT, CANAL ZONE²

THE marl shales, through which Culebra Cut extends, in the region opposite the Culebra railway station, have, from time to time, on exposure to the atmosphere, become hot. The intensity of this heat has varied from noticeably warm to a temperature sufficient to readily char wood, without, however, causing it to burst into a flame. The duration of this heating has been from a few days to several weeks. These shales are dark, thin bedded, soft and easily crumbled, and some of the layers are largely fine basic tuff, loosely cemented by lime. Other beds contain more carbonaceous material, with some local partings of lignite an inch to a foot or more thick. The relatively unweathered character of these basic sediments is evidence that they were derived from nearby volcanic mountains, and the carbonaceous and lignitic layers in them indicate shallow water and swamp conditions of deposition. The presence of fossil oysters, pelecypods, corals and foraminifera show that these shallow estuaries were marine, and that they existed in early Tertiary time. Dr. T. Wayland Vaughn, of the U. S. Geological Survey, examined some of the specimens on the ground and gave it as his opinion that they are Oligocene in age. The evidence so far points to a shallow water connection between the Atlantic and the Pacific during Oligocene time.

¹ This review was written immediately before the lamented death of Professor Rotch.—Ed.

² Published by permission of the chairman of the Isthmian Canal Commission.

After exposure to the atmosphere by drilling, or blasting, certain local areas of this formation become, in the course of a few days, warmed up, and as the heating goes on the carbonaceous matter in the shales is gradually oxidized off and they tend to assume a gray to dull reddish color. The first working hypothesis entertained in looking toward a solution of this heating phenomenon was that possibly the heavy blasting had furnished heat enough to break down the calcium carbonate present to the oxide form, and that ground water and atmospheric moisture reacted on this to slake it and thus probably generate sufficient heat to start the oxidation of the carbonaceous material. This hypothesis was, however, rendered untenable by three lines of evidence:

1. The heating was much more local than the calcium carbonate, and the carbonaceous matter.
2. The heating bore no definite relation to the lime and carbon content of particular beds.
3. Colonel Gaillard, in charge of the Division, informs me that in some instances the heat began in the holes some time after they had been drilled, but before the ground had been blasted at all.

Another line of inquiry was suggested by finding a small amount of pyrite in some of the beds which were heating. It was suspected that this, through its oxidation, was a factor in furnishing the initial heat of the action. In April, 1911, samples of the beds then heating were sent to the chemical laboratory of the U. S. Geological Survey with instructions to make qualitative tests for sulphur and other products that might serve, through oxidation, as the mainspring of the action. These tests revealed the presence of sulphuric acid to the amount of 1.92 per cent., also minute crystals of gypsum. This confirmed the hypothesis that pointed to the pyrite present as the substance acted on by atmospheric oxygen to develop the initial heat.

The most aggravated case of heating so far noted is now going on in Culebra Cut, about 350 yards north of the foot of the stair at the observation tower near Culebra Station. The

mass of heated ground here is about 500 feet long by 20 feet wide, and the action reaches a depth of perhaps 15 or 20 feet. Blue smoke, which contains a high percentage of sulphur-dioxide, issues from vents in the mass, and fragments of wood inserted in these are readily charred and consumed. A small amount of steam may also be detected emanating from local moist spots, but this is mainly due to the vaporization of ground water. In the investigation of this heated mass samples were taken, and these were tested qualitatively for sulphuric acid and for sulphates of calcium, aluminium and magnesium. The tests were made by Mr. Jacobs, of the Hospital Laboratory Staff at Ancon, and they revealed the presence of all of the above substances, both in the shale and as the white coating on the moist spots and steam vents of the mass. The yellow deposit near the larger vents is sulphur. Sulphuric acid, especially, was shown to be present in considerable quantity. The origin of the sulphuric acid here was at first a puzzle, because the examination of many samples, with the naked eye and with the microscope, failed to reveal the presence of pyrite. Finally samples of eight to ten pounds were taken, ground with water in a large mortar for some minutes, and then concentrated to a few ounces by washing or "panning." This concentrate showed a high content of pyrite, much of which could scarcely be seen with the naked eye. Under the microscope very small crystals of pyrite were noted; also considerable magnetite, present as black sand, and some sub-angular to fairly rounded grains of quartz.

The mainspring of the action here then, as in the other instances observed, has undoubtedly been the oxidation of the pyrite. The reasons why this oxidation has been so rapid and effective, seems to be as follows:

(a) The finely divided, almost microscopic, character of the pyrite gives maximum surface exposure to atmospheric agencies and greatly promotes oxidation.

(b) The very warm, moist atmosphere. The tropical sun shining directly on dark rock surfaces produces a temperature sufficiently

high to greatly promote oxidation, especially in the presence of slight moisture.

(c) Once oxidation of the pyrite has been started the heat thus generated tends to accelerate chemical action and thus the heating increases in geometric progression.

(d) When the heat of pyrite oxidation reaches the comparatively low temperature of oxidation of the hydrocarbons present in the lignitic shale, they, too, become oxidized and still further add to the temperature. Finally the fixed carbon content tends to become oxidized, at least in part, and gives maximum intensity to the action.

(e) Some heat is also generated by the action of the free sulphuric acid on the calcium carbonate for the formation of gypsum. Other minor chemical actions added their quota to the total heat.

As the temperature rises all chemical activity is vastly stimulated and the heating increases to a maximum. After the most readily oxidizable substances are consumed the heat gradually dies down toward normal temperatures, which may be reached in a few weeks or months. The intensity and duration of the heat depends largely upon the percentage of finely divided pyrite, volatile matter and fixed carbon in the rocks.

Some of the geological considerations suggested by a study of this phenomenon are:

(a) Chemico-thermal springs. Whenever jointing fissuring or change of groundwater level gives free access of oxygen-bearing surface waters to beds which contain the necessary finely divided pyrite, and carbonaceous matter, a heating up of such beds is likely to result. Groundwater flowing over such heated beds, and coming to the surface in the general vicinity of them, would constitute thermal springs.

(b) Should a rise of land surface bring pyrite-bearing beds from subaqueous to terrestrial conditions, oxidation of the pyrite might, in the course of a year, give local redbeds that would otherwise require centuries of atmospheric action to produce. Of course it is recognized that no very extensive redbeds could be produced in this way.

(c) The very fine pyrite sparingly disseminated through the carbonaceous shales, herein described, seems to have resulted from the action of sulphur, from decaying animal and vegetable life, on the ferro-megnesian silicate fragments which are abundant in these sediments.

DONALD F. MACDONALD,
Commission Geologist

CULEBRA, C. Z.,
April 1, 1912

THE ASTRONOMICAL AND ASTROPHYSICAL SOCIETY OF AMERICA

WASHINGTON MEETING, DECEMBER, 1911

THE thirteenth session of this society was held at the Carnegie Institution in Washington, D. C., on December 27-29, 1911, with President E. C. Pickering in the chair. There were sixty-four members of the society in attendance besides many friends. Nine persons were elected to membership, making a total of more than 270 members.

Six sessions were held, two of which were joint meetings with Section A of the American Association for the Advancement of Science. At the joint sessions Professor E. B. Frost presided in the double capacity of vice-president of Section A and first vice-president of the Astronomical and Astrophysical Society of America; and for these sessions a special program was arranged comprising addresses by Professor Lewis Boss on "Recent Researches as to the Systematic Motions of the Stars," by Professor E. H. Moore, retiring vice-president of Section A, on "The Foundations of the Theory of Linear Integral Equations" and by the Reverend Joel H. Metcalf on "The Asteroid Problem."

The society's scientific program included thirty-two papers and also reports from the committees on comets, photographic astrometry and cooperation in the teaching of astronomy. A new committee on asteroids was created with members, E. W. Brown (chairman), J. H. Metcalf, G. H. Peters and A. O. Leuschner.

The following members were in attendance at the Washington meeting: Misses L. B. Allen, H. W. Bigelow, A. J. Cannon, M. M. Hopkins, E. A. Lamson, Mary Proctor, S. F. Whiting, Messrs. A. T. G. Apple, E. E. Barnard, S. G. Barton, L. A. Bauer, L. Boss, J. A. Brashear, E. W. Brown,

C. A. Chant, H. S. Davis, C. L. Doolittle, E. Doolittle, R. S. Dugan, J. C. Duncan, J. R. Eastman, W. S. Eichelberger, F. E. Fowle, E. Friaby, E. B. Frost, C. H. Gingrich, A. Hall, W. M. Hamilton, J. C. Hammond, H. B. Hedrick, G. A. Hill, W. J. Humphreys, H. Jacoby, H. H. Kimball, W. F. King, F. B. Littell, F. H. Loud, E. O. Lovett, C. A. R. Lundin, Jr., J. H. Metcalf, W. I. Milham, J. A. Miller, S. A. Mitchell, W. M. Mitchell, H. R. Morgan, C. P. Olivier, G. H. Peters, E. C. Pickering, J. S. Plaskett, R. W. Prentiss, W. F. Rigge, F. E. Ross, A. L. Rotch, H. N. Russell, F. Schlesinger, A. N. Skinner, H. T. Stetson, O. Stone, E. D. Tillyer, A. B. Turner, F. D. Urie, R. W. Willson, D. T. Wilson, R. S. Woodward.

New members were elected as follows: John August Anderson, Johns Hopkins University, Baltimore, Md.; Zaccheus Daniel, Allegheny Observatory, Pittsburgh, Pa.; Walter M. Hamilton, 2307 Washington Circle, Washington, D. C.; H. H. Kimball, Weather Bureau, Washington, D. C.; William Francis Rigge, Creighton University, Harlow Shapley, The Observatory, Princeton, N. J.; Vesto Melvin Slipher, Flagstaff, Ariz.; Albert Harris Wilson, Haverford, Pa.; Charles Clayton Wylie, Laws Observatory, Columbia, Mo.

The program of the meeting included the following papers and reports:

A Device for Facilitating Various Forms of Computation: E. W. BROWN.

The device consists of a frame and a carrier which supports a number of tapes. On these tapes small oblong pieces of cardboard are pasted, the members to be summed being written on the pieces of cardboard. It is essentially a device for avoiding the frequent rewriting of the same number when it has to enter into a calculation in many different ways. It is being used for the summation of many small harmonic terms at numerous time-intervals and for the formation of double-entry tables which consist of ten or more terms of the type $A \cos (i\theta + j\phi + a)$ where i, j are integers, a, A constants and θ, ϕ increase uniformly with the time. It will probably be also used for the analysis of numerous observations at equal time-intervals into harmonic terms whose periods are known or have been previously determined, as, for example, in obtaining the tidal constants of a port from hourly observations of the tide height.

The Lesson of Joseph Piazzi's Life: H. S. DAVIS.

Piazzi's career is followed from his birth, through

his student days in Milan, Turin and Rome, and his professional days in the universities of Genoa, Malta, Ravenna, Cremona and Rome, and while getting wider experience in Paris and Greenwich preparatory to beginning his long period of astronomical observations at Palermo, where he built an observatory on the royal palace.

The method of his observing for the large catalogue of stars, his discoveries of certain stellar proper motions, his wide range of observations and of writings on astronomical and geodetic subjects, are narrated to elucidate the influence which this Theatine priest exerted on the science of his and later days, and inversely to exemplify the influence which had been exerted on him by his environment and by his intercourse with Laplace, Lagrange, Delambre, Bailly, Cassini, Herschel, Wollaston, Oriani, Cagnoli and other notable men of astronomy. It is further shown how his discovery of Ceres was not altogether an accident, nor by any means his greatest achievement, but was the natural by-product of his plan of work and his persistent diligence; and that all the many and valuable fruits of his quarter-century of labor were but the outgrowth of an unselfish devotion that had adopted as its motto the words of Seneca: "At mehercules non aliud quis aut magnificentius quæsierit aut didicerit utilius, quam de stellarum siderumque natura."

(This paper will be published *in extenso* in "Makers of Astronomy," soon to be issued by the Fordham University Press, New York, as companion to "Makers of Electricity.")

The Astronomischer Jahresbericht (an Announcement): H. S. DAVIS.

A brief historical summary of the founding and maintaining of this review of astronomical publications, its plan and scope, and to what extent its purpose has been attained. Its future, since assumption of the editorship by Professor Dr. Fritz Cohn, on the retirement of Dr. Berberich, who succeeded to the editorship on the death of Professor Dr. Wislizenus, its founder.

The Variability of Polaris: JOEL STEBBINS.

The variation in the light of Polaris was detected by Hertzsprung and confirmed by King. Assuming the spectroscopic period of 3.9681 days, Hertzsprung found the light-curve to be approximately a sine-curve with double amplitude 0.17 mag., and King found a similar curve with variation greater than 0.10 mag. Both of these results were from photographs. Observations by the writer with the selenium photometer give a similar

curve of the same phase, but of much smaller amplitude, the approximate range being 0.057 mag. It is highly probable that the amount of the visual variation is likewise about 0.06 mag.

The Asteroid Problem: JOEL H. METCALF.

In ninety years from January 1, 1801, to 1891, 323 asteroids were discovered. In the last twenty years about 427 have been added. The rapid multiplication of discoveries and the probable existence of 1,500 brighter than the 14th magnitude demands greater cooperation and division of labor in this field. Except for special investigations the work should be photographic, which gives great facility for observation of old asteroids as well as the discovery of new ones. The importance of the investigation in the light of the discovery of Eros and the Jupiter group of asteroids and the probable existence of still more interesting bodies is increasingly obvious.

Magnitudes, Colors and Spectra of Standard Stars within 17° of the North Pole: J. A. PARKHURST.

This paper describes the determination of the "visual" and photographic magnitudes, color-indices and spectral classes of all the stars down to the B. D. 7.5 magnitude, from declination + 73° to the north pole. There are 666 stars within these limits. The instrument used was a camera having a Zeiss doublet of "ultra-violet" glass, also a 15° prism of the same material. The aperture of each is 145 mm. and the focal length of the lens 814 mm.

The photographic magnitudes were taken from Seed plates exposed 6.5 mm. inside the focus, and the opacity of the images was measured with a Hartmann "mikrophotometer." To obtain the "visual" magnitudes images were taken in focus on Cramer trichromatic plates through a "visual luminosity" filter, and the diameters of the images measured under the microscope. The spectral classes were estimated on the Harvard system from the objective prism plates. The magnitude scale was determined on the "absolute" system, directly by sensitometer squares on the extra-focal plates, and indirectly through the Pleiades stars on the focal plates. The measures were reduced by using the Müller and Kempf Potsdam visual magnitudes of the white stars in each field, and reduced to the Harvard system by subtracting 0.29.

Curves were shown giving comparisons with the results of Schwarzschild, Müller and Kempf and Mrs. Fleming; also the relation between color-index and spectral class, and between the color-index and Müller and Kempf's estimates of color.

A Comparison of Dr. Peters's Celestial Charts with the Photographic Charts of the Sky: J. G. PORTER.

The value of star-charts lies, first, in the completeness with which they represent the sky, and secondly, in their availability for use at the telescope.

Four of the photographic charts of the sky, taken at Algiers and Bordeaux, were compared with Dr. Peters's celestial charts, the stars in corresponding regions being carefully counted. In every case the photographic charts contain fewer stars, the percentages running from 51 to 81, and the average being 67 per cent. That is, the visual charts contain on the average 50 per cent. more stars than the photographic charts.

Dr. Peters's charts are pretty complete down to the twelfth magnitude. The photographic charts, therefore, are by no means complete to the twelfth magnitude.

On the photographic charts the images of all but the brighter stars are too faint to see without brilliant illumination, and the configurations of the fainter stars are difficult to trace. Hence these charts are ill suited for use with the telescope.

Two conclusions follow from this comparison. First, the visual charts, so far from being superseded by the photographic charts, are much superior both in their fullness and in their practical usefulness.

Secondly, the photographic charts while ostensibly showing stars to the fourteenth magnitude, really go hardly lower than the eleventh and a half. Some of this discrepancy may be due to the difference between the photographic and visual scales; yet in any case it is clear that in the matter of these charts photography has accomplished far less than was claimed for it, and less than should have been done to justify the expenditure of time and money.

The New Twin Photographical Telescopes of the U. S. Naval Observatory: GEORGE H. PETERS.

This paper is a continuation of one given at the meeting of the society at the Yerkes Observatory in 1909, entitled, "On the Construction of Astronomical Photographic Objectives at the Naval Observatory." It describes the progress in construction and adjustment of the triple photographic objectives of 10 inches aperture and 110 inches focal length. These new lenses and their mechanical parts, forming a twin photographic telescope, are now practically completed, and are

erected in position on the old 28-inch mounting. The tests for errors of adjustment in collimation and refraction are exemplified, together with the methods employed in correcting them.

The Use of Special Topics in Teaching Astronomy: SARAH F. WHITTING.

The large numbers who should study elementary astronomy for information and culture should be taught to handle the books of an astronomical library and to express themselves clearly in connected discourse.

To these ends a method more frequently used in literary subjects may well be used—the method of "special topics." A large class for this exercise must be divided into parallel sections; the topics must be given out with bibliography and suggested outline, and the presentation of the topics before the class rated for excellence of outline, form of presentation in language and manner.

Such series of topics as the following have been found practical.

1. Historical topics, some of which may be presented in connection with the biographies of astronomers.

2. A series of topics to show the knowledge of astronomy at different epochs—astronomy of the Bible, astronomy of Homer, astronomy of Milton, astronomy of Shakespeare.

3. The progress of astronomy as related to instruments and mathematical methods. The development of the telescope, of calculus, logarithms, etc.

4. A set of topics to show the immense cost in money and labor to obtain facts—eclipse expeditions, expeditions to obtain solar parallax.

5. Great observatories.

6. Special studies of celestial objects—Halley's comet, net in Orion, etc.

The Orbit of the Spectroscopic Binary, β Scorpii: J. C. DUNCAN.

The variability of the radial velocity of the brighter visible component of β Scorpii was discovered by Dr. V. M. Slipher at the Lowell Observatory in 1903. In 1908 he found that the star's spectrum showed a sharp, non-shifting K line. The writer of the present paper has determined the orbit of the binary from seventy-nine spectrograms made by Dr. Slipher in 1908, 1909 and 1911.

Measurement of the spectrograms was rendered difficult by the scarcity and diffuseness of the spectral lines. In addition to the K line, two

lines of hydrogen and three of helium were all that could be measured. The H line of calcium is concealed by the broad H of hydrogen. On some of the plates the presence of the fainter component of the binary is made evident by the doubling of the lines of hydrogen and helium, so that on these plates three different velocities are indicated—that of each component of the binary and that of the K line.

The orbital elements derived are as follows:

	Bright Com.	Faint Com.
Period, P	6.8292	
Eccentricity, e . .	0.25	
Time of periastron, T	1908 July 2.98	
Dist. node to periastron, ω	20°	200°
Semi-amplitude of vel. curve, K . .	126 km./sec.	166 km./sec.
Maximum velocity	+150 km./sec.	+120 km./sec.
Minimum velocity	—102 km./sec.	—211 km./sec.
Projected semi-axis major, $a \sin i$. .	11,457,000 km.	15,094,000 km.
Ratio of masses .	1:0.91	
Velocity of system	—6.0 km./sec.	
Velocity of calcium	—16.4±0.6 km./sec.	

The velocity of the calcium differs by ten kilometers per second from that of the center of gravity of the binary system—a difference that seems too great to be explained by errors of measurement or of the assumed wave-lengths. Since a uniformly moving mass accompanying the system would be expected to have a velocity equal to that of the common center of gravity of the revolving stars, this investigation may be regarded as tending to support the hypothesis, favored by Slipher and others, of a detached calcium cloud in the line of sight.

There is some indication that the period is slowly lengthening. It is hoped that data derived from some older plates by Dr. Slipher may decide this point. This will also have a bearing on the question of the location of the calcium since, if the star is involved in a cloud of calcium or other substance, the friction should cause the period to shorten.

The Dissolution of Solar Prominences: **FREDERICK SLOCUM.**

Among the photographs of solar prominences at the Yerkes Observatory there are several series which show prominences in the act of dissolving. In general the prominences dissolve in one of the four following ways:

1. By floating up and dissipating like smoke from a fire.
2. By ascending and contracting into a long, fine filament.
3. By being torn into fragments and borne away as if by a strong wind.
4. By dissolving *in situ* like the trail of a meteor.

These processes were illustrated by lantern slides giving series of views of the prominences of June 19–20, 1911; September 19, 1911; July 25–29, 1908; March 25, 1910, and single views of other prominences.

All of the photographs were taken in the light of the H line of calcium with the Rumford spectroheliograph attached to the 40-inch telescope.

The Parallax of Nova Lacertæ 1910: **FREDERICK SLOCUM.**

Nova Lacertæ was discovered by Espin December 30, 1910. During the year 1911 ten photographs of the region around the Nova were made with the 40-inch telescope for the purpose of determining the parallax of the star. Cramer instantaneous isoplates were used in connection with a yellow color filter. In general two exposures were made on each plate. The exposure time was increased from 5 to 15 minutes as the star diminished from somewhat brighter than the 8th down to the 12th magnitude. Six comparison stars were selected as symmetrically situated as possible, and as near as possible to the mean brightness of the Nova. The parallactic displacement parallel to the ecliptic was measured. The value of the parallax came out +0".013 with a probable error of ±0".014. This would mean that the outburst observed in 1910 really occurred 250 years ago.

A Simple Pyrheliometer: **W. J. HUMPHREYS.**

This instrument consists essentially of a spherical Dewar bulb filled with mercury and provided with means for absorbing solar energy and measuring its effect.

A hollow platinum cone, polished on the inside, about seven centimeters long and with an opening one centimeter in diameter is symmetrically immersed in the mercury and set so that it will receive sunshine through a suitable system of diaphragms. Such a cone is well nigh a perfect absorber of radiation parallel to its axis, and as constructed the heat absorbed is rapidly transmitted to the mercury, the expansion of which is measured in a thermometer stem.

The readings consist in taking the time interval during the expansion of the mercury up the ther-

meter stem from one to another fixed point. Provision is made whereby, after one time interval has been obtained, the mercury can be set back below the first mark, and then another interval read, and so on as long as necessary.

The intensity of the insolation is inversely proportional, approximately, to the above time intervals—the times required for delivering substantially equal amounts of heat to the mercury.

While capable of development as a standard it was designed as a secondary instrument, the chief features of which are:

1. Essentially complete absorption of insolation.
2. Unchanging coefficient of absorption.
3. Highest possible heat insulation.
4. Freedom from calibration.
5. Ease of manipulation.

The Violle Actinometer as an Instrument of Precision: F. W. VERY.

The principal objects of this research are to show that the Violle actinometer may be used either dynamically or statically with equal precision, and to develop the theory of its static use.

Hitherto the rates of cooling of a thermometer in a partial vacuum have been used to get an estimate of losses by convection in an actinometer in air, but these measures have not differed essentially from the experiments of Dulong and Petit, and are quite inadequate, since they entirely neglect the losses by penetration of gaseous molecules. It is very commonly assumed that the velocity of cooling in "vacuum," obtained by Dulong and Petit,

$$V = k((1.0077)^{t+\theta} - (1.0077)^t),$$

represents a law of *radiation*; but this is not the case, since the observations included both radiation and penetration, and the latter is by no means insignificant.

By the use of Stefan's law for pure radiation, I first separated the radiant component, and from experiments by Langley and myself, and by Kundt and Warburg, I derived a preliminary value of the penetration in C.G.S. units,

$$P = 0.0001397 \theta.$$

This, however, did not represent the observations so closely as could be wished, and it was evident that dimensions and form of both radiating body and enclosure must enter into a complete theory. Taking Winkelmann's value of K (the constant of penetration for a plane surface in C.G.S. units), calling r the radius of the thermometer-bulb,

l the distance to the enclosing surface, and θ the temperature of excess, and reducing to minutes,

$$P = 4K\theta \times \frac{4\pi r^2}{l} \times 60.$$

With this formula the penetration was computed for two thermometers used by Langley on Mount Whitney in a Violle actinometer with the following result:

$\theta = 30^\circ \text{ C.}$, Green 4,572, cooling per minute by penetration, $-2^\circ.248$; observed, $-2^\circ.08$.

$\theta = 30^\circ \text{ C.}$, Baudin 8,737, cooling per minute by penetration, $-2^\circ.588$; observed, $-2^\circ.84$.

The convection loss can be represented by the formula

$$C = c \times \theta^{1.25} \times (p/p_1)^{0.45},$$

where

$$c = 0.000,005,02 + \frac{0.000,036,76}{r} \text{ (C.G.S.)},$$

a value determined by myself. p and p_1 are actual and normal barometric pressures, and the exponents are those of Dulong and Petit. For the given excess and Baudin thermometer,

Loss of temperature per minute by convection

$$= -4^\circ.153$$

Loss of temperature per minute by penetration

$$= -2^\circ.588$$

Loss of temperature per minute by radiation

$$= -2^\circ.890$$

$$\text{Computed total loss} = -9^\circ.636$$

$$\text{Found} = -9^\circ.2$$

The final difference of about $0^\circ.4$ includes errors of observation and also stem conduction which in this case was towards the bulb, or positive, the thermometer having been previously heated as a whole.

With some minor emendations relating to the general theory of the instrument, which can not be described here, I obtained from Keeler's observation with the Violle actinometer on the summit of Mt. Whitney:

Solar radiation at noon from initial rate of heating
= 1,995 cal. per sq. cm. per min.

Solar radiation at noon from static temperature
= 2,001 cal. per sq. cm. per min.

The difference in the results by the two methods is insignificant.

Improvements are suggested in the mounting and use of the instrument, and certain necessary precautions which have sometimes been neglected are described.

The Revised Draper Catalogue: ANNIE J. CANNON.

Owing to a general desire among astronomers for the class of spectrum of many more stars than have yet been studied, work has been begun upon a new catalogue of stellar spectra, to be called the Revised Draper Catalogue. The whole sky will be covered by photographs taken with a prism placed in front of the object glass of the 8-inch Draper and Bache telescopes, the exposure being generally one hour. It is believed that all stars of the eighth magnitude will be included, as well as many fainter ones. All the classification will be made by the writer, using the notation described in the *Harvard Annals*, volume 56, pages 66 to 69.

This work can be done rapidly, since previous study and classification of more than five thousand spectra taken with the various Harvard telescopes have made each division and subdivision a definite picture in the mind. Three assistants are working daily upon the laborious identifications, the reductions and the clerical part of the catalogue. Seven thousand spectra have already been classified, and it is estimated that if we have equally good photographs for the whole sky, the catalogue will contain one hundred thousand stars. It is proposed to print it in sections in the order of right ascension, of which the portion from 0^h to 6^h will form the first volume.

Notes on the Determination of the Elements of Algol Variables: H. N. RUSSELL.

Further study of this problem on which a report was made to the society in August, 1910, shows that, when there is no constant period at minimum (i. e., when the eclipse is partial), it is possible to represent the observed light curve within the error of ordinary observations by arbitrarily choosing any value within certain limits for the ratio of the radii of the two stars, and then determining the other elements in a suitable manner.

The various sets of elements, however, give different depths for the secondary minimum; and if this has been observed the problem becomes determinate, unless the primary and secondary minima are of nearly equal depth. In the latter case additional data (which can sometimes be supplied by spectrographic observation) are necessary if the elements are to be definitely determined.

Tables have been prepared which facilitate the numerical solution of these problems. With slight modifications, these may also be used in the case of variables of the Beta Lyrae type, in which the two stars are very close, and are distorted into prolate ellipsoids by their mutual attraction.

The Eclipsing Variables W Crucis and W Ursae Majoris: H. N. RUSSELL.

Good light-curves of these stars have been determined, the first at Harvard by Miss Leavitt, the second at Potsdam by Muller and Kempf and by Baldwin. Both are of the β -Lyrae type, and in each case the observations can be very satisfactorily represented on the eclipse theory.

W Crucis has a period of 198.5 days and a range from $8^m.9$ to $9^m.5$, with a secondary maximum of $9^m.2$. The system consists of two stars, one twice as bright and two and a half times as large as the other. The ratio of the longer and shorter axis of the ellipsoidal stars is 7:6. The relative orbit has an eccentricity of 0.04, and at periastron the surfaces of the two stars are separated by a distance slightly exceeding the diameter of the smaller. At principal maximum the smaller star is totally eclipsed by the larger. Increase and decrease of light lasting 14 days and totality 15 days.

The density of the larger star can not exceed $1/160$ that of the smaller star, $1/10$ that of the air under ordinary conditions. The spectrum is G pec. with bright lines.

This system is evidently in a very early stage of development, and if comparable with the sun in mass and surface brightness, must be at a distance of many thousand light-years.

The writer is greatly indebted to Professor Pickering and Miss Leavitt for unpublished observations of this star.

W Ursae Majoris varies from $7^m.9$ to $8^m.5$ in a period of 8 hours, within which there are two equal and equidistant maxima and minima. Its variations may be very satisfactorily represented on the assumption that the system consists of two stars, equal in size and brightness, with longer axes $4/3$ of the shorter axes, revolving in a circular orbit, and separated by only $2/5$ of their longer diameters. At maximum one star obscures half the disk of the other, the eclipse lasting one and a half hour.

The light-curve may be equally well represented with any ratio of the two radii between unity and 0.57—the surface brightness of the two stars being equal. The mean density of the system is 2.4 times the sun. This star is also of Spectrum G, but must represent a very different stage of evolution from the other.

The Solar Rotation: J. S. PLASKETT.

This paper gives an account of further work on the spectroscopic determination of the solar rota-

tion, a preliminary paper having been given at the last meeting. It includes a discussion of the measures of 110 spectra at seven different latitudes in the region $\lambda 5,500$ – $\lambda 5,700$ and of 24 spectra at the equator in the region $\lambda 4,200$ – $\lambda 4,300$. The value of the rotational velocity at the equator is at

$$\begin{aligned}\lambda 5,600, v + v_1 &= 2.021 \pm .003 \text{ km. } \xi = 14^\circ.35, \\ \lambda 4,250, v + v_1 &= 2.012 \pm .003 \text{ km. } \xi = 14^\circ.29,\end{aligned}$$

where $v + v_1$ is the linear and ξ the daily angular sidereal velocity. The law of equatorial acceleration or polar retardation follows the Faye form, having the following coefficients:

$$\begin{aligned}v + v_1 &= (1.306 + .701 \cos \phi) \cos \phi \\ &= 10^\circ.84 + 3^\circ.51 \cos^2 \phi.\end{aligned}$$

A comparison of ξ for different determinations gives

Sun Spots	Faculae	Floculli	Reversing Layer			
			Duner	Halm	Adams 1906-7	Plas- kett
14.40	14.62	14.55	14.81	14.53	14.63 1908 14.61	14.35

Whether the smaller value obtained here is due to some systematic error or to a variation in the rate of rotation there is as yet insufficient evidence to determine. It may be pointed out that the Ottawa observations were obtained at sun-spot minimum and the major part of the others more towards maximum.

A comparison of the residuals from lines of different elements in both regions indicates that any systematic deviations found, not greater except in one case than one third the average residual, are due to some personal systematic effect in measurement and not to differences of the rotational velocity in different elements.

The Moon's Mean Parallax: F. E. ROSS.

The following values of the lunar parallax and related quantities are based upon the constants of the geoid obtained in 1909 by the U. S. Coast and Geodetic Survey and upon Hinks's value of the moon's mass.

$$\begin{aligned}P_0 &= 3,422''.526 \pm 0''.012, \\ \Delta &= 238,857.9 \pm 1.1 \text{ U. S. statute miles,} \\ S &= 1,079.93 \pm 1.04 \text{ miles,} \\ D &= 0.6043 \pm .0008.\end{aligned}$$

P_0 is the constant of the sine parallax, Δ the mean distance, S the semi-diameter, and D the density

in terms of that of the earth. The correction to Hansen's parallax is

$$\delta H = + 0''.45.$$

Observations on the moon's limb for the determination of the parallax seem to be subject to large systematic errors. The results obtained by Olufsen, Henderson, Breen, Stone and Batterman lead to a value of 304 for the reciprocal of the earth's flattening. This systematic error seems to be largely eliminated in the recent Greenwich-Cape series of observations on the lunar crater Moesting A. The value of the reciprocal of the flattening resulting from this series is 294.45. It is likely that considerable further improvement in the results by the observational method would be obtained by the adoption of a photographic method.

The Secular Variations of the Elements of the Orbits of the Four Inner Planets: ERIC DOOLITTLE.

This paper presents the results of a computation extending over upward of sixteen years which had for its object a new determination of the perturbations of the orbits of the inner planets based on the most accurate elements now obtainable. The method employed differed from that of Le Verrier and Newcomb in that it depended upon the evolution of certain integral expressions instead of on the use of infinite series. Every possible device to insure accuracy was employed, the entire computation being duplicated and all known test equations applied. The well-known discrepancies which exist between certain of the variations as derived from theory and their values as determined from observation merely were fully confirmed. The figures expressing the motions of the perihelion of Mercury, the node of Venus, the perihelion of Mars and the eccentricity of Mercury, respectively, are as follows.

Newcomb	New Computation	Observation
+ 109''.76	+ 108''.91	+ 118''.24
— 106''.00	— 106''.00	— 105''.40
+ 148''.80	+ 148''.74	+ 149''.55
+ 4''.24	+ 4''.235	+ 3''.36

The Language of Meteorology: C. F. TALMAN.
(Introduced by W. J. Humphreys.)

Scientific language is nowadays a somewhat neglected subject, and contemporary men of science show a reluctance to label their contributions to knowledge.

In meteorology there is need not only of new terms, but of a much more general use of the terms already introduced and adapted to their

purpose. A very large part of the meteorological vocabulary is unfamiliar to meteorologists. This is illustrated by the case of the "isograms." Upwards of eighty of these lines have been given appropriate names; but not a score of these names are in current use.

In no branch of science is the vocabulary more confused than in atmospheric optics; especially in English. One can hardly write of any but the commonest photometers without defining almost every term one uses. Thus the words "glory," "corona," "aureole" and "anethelion" are variously applied and interchanged; the Brocken specter is confused with the Brocken bow; etc.

Among meteorological neologisms the term "aerology," meaning the branch of science concerned with free-air investigations, deserves a wider use; "stratosphere" is the best name for the region of the atmosphere now more generally called the "isothermal layer"; Arctowski's terms "pleion" and "antipleion" are useful additions to the vocabulary; Dr. H. R. Mill's discrimination of "mean," "average" and "general" will obviate the confusion that heretofore reigned in the use of these words; the application now given in Great Britain to the terms "rime" and "glazed frost" is commended to general attention; L. Beson's name "nephometer" seems appropriate for an instrument used to measure the amount of cloudiness; the derivatives of the new German names for the snow-gauge ("chionometer," "nivometer") are likely to come into general use (i. e., we shall use "nivometric," etc., though we may not adopt the noun); Odenbach's "cer-aunograph" is a good international name for the thunderstorm-recorder; the American name "kiosk" gives us a tolerable English equivalent for "Wettersäule."

An international commission on meteorological terminology is an urgent desideratum.

Can Astronomy Derive Benefit from the Dissemination of Esperanto? F. H. LOUV.

The paper first pointed out some of the easily verifiable indications of the entrance of Esperanto upon the stage of practical utility in the ordinary relationships of life, and proofs of the increasing popular acquaintance with it, especially in Europe; and then, passing to the consideration of its possible utilization in the service of astronomy, suggested its employment (1) in the oral discussions and the reports of international conventions, (2) in astronomical treatises, where, in the field of pure mathematics, for instance, such an example

has already been set as the work of Dr. Cyril Vörös, of Budapest, on "Absolute Geometry"—a book (including its three sections) of 439 pages, and of high scientific value, and (3) in the dissemination of astronomical news, through the *Internacia Sciencas Asocio* and other channels, where, though the direct service were rather to the general public than to professional astronomers, yet the science would ultimately receive benefit.

On the Flexure of a Meridian Circle: W. S. EICHELBERGER and H. R. MORGAN.

From 1903 to 1911 the flexure of the 9-inch transit circle of the Naval Observatory was determined from measures on collimators. The circle was shifted for each of the six clamp years, and at the end of the work, and the circle flexure distinguished from the tube flexure.

The table gives the division of the circle at the object glass end, the means of the measures on the collimators for each position, and the residuals from the solution of the fourteen equations.

The first eight equations result from 70 sets of measures on the horizontal collimators, and the last six from 68 sets of measures on the vertical collimator and nadir.

	<i>O</i>	<i>Wt</i>	<i>O-C</i>
$x_s + y \cos (A - 270^\circ 4') = -0".95$	3	+ 0".11	
$x_s + y \cos (A - 269^\circ 56') = -1".14$	6	+ 0".08	
$x_s + y \cos (A - 264^\circ 52') = -1".02$	6	- 0".04	
$x_s + y \cos (A - 259^\circ 40') = -0".74$	13	+ 0".16	
$x_s + y \cos (A - 256^\circ 28') = -0".99$	18	- 0".15	
$x_s + y \cos (A - 261^\circ 34') = -0".89$	6	+ 0".04	
$x_s + y \cos (A - 261^\circ 16') = -0".85$	9	+ 0".07	
$x_s + y \cos (A - 81^\circ 16') = + 0".35$	9	0".00	
$x_c - y \sin (A - 264^\circ 52') = + 1".08$	10	+ 0".12	
$x_c - y \sin (A - 259^\circ 40') = + 0".85$	14	+ 0".17	
$x_c - y \sin (A - 256^\circ 28') = + 1".13$	12	+ 0".08	
$x_c - y \sin (A - 261^\circ 34') = + 1".07$	14	+ 0".07	
$x_c - y \sin (A - 261^\circ 16') = + 0".93$	9	+ 0".07	
$x_c - y \sin (A - 81^\circ 16') = - 0".96$	9	- 0".03	

The solution gave: the coefficient of the sine flexure of the tube, $x_s = -0".289$; the coefficient of the cosine flexure of the tube, $x_c = + 0".037$; the coefficient of the flexure of the circle, $y = + 1".156$; the point of maximum weight of the circle, $A = 137^\circ 55'$. To test the sine law, 264 direct and reflected star observations were taken, on both clamps, and both sides of the zenith. The solutions in the table give the error of the nadir, or cosine flexure; a term for bisection error, or other discontinuity at the zenith; and the sine flexure.

Clas No. Nights	$\frac{1}{2}(R-D)$	Mean Residual
E 5	$-0''.71 \pm 0''.34 - 1''.14 \sin z$	$\pm 0''.19$
W 2	$-1''.11 \pm 0''.34 - 1''.11 \sin z$	$\pm 0''.15$
W 4	$-1''.01 \pm 0''.83 - 1''.11 \sin z$	$\pm 0''.15$
W 2	$-1''.60 \pm 0''.40 - 1''.11 \sin z$	$\pm 0''.17$
W 2	$-1''.48 \pm 0''.28 - 0''.58 \sin z$	$\pm 0''.16$
W 2	$-1''.07 \pm 0''.71 - 1''.37 \sin z$	$\pm 0''.18$
E 2	$-0''.81 \pm 0''.22 - 0''.77 \sin z$	$\pm 0''.28$

The agreement with the collimator measures is satisfactory. To test the cosine law, 20,000 star observations, corrected for division error, bisection error, variation of latitude and flexure, were differenced for successive clamp years. The mean values of $(S_w - S_e)$ are:

$$-0''.24, -0''.23, -0''.23, -0''.03, -0''.11.$$

The residuals from these means were solved in the form

$$0''.04 \cos z - 0''.11 \cos 2z.$$

This reduced the mean residual from $0''.09$ to $0''.08$, only, and has not been used. The mean differences $(S_w - S_e)$ were attributed to the uncertainty in the various nadir division errors. The corrections, following, were, therefore, applied to the different years; their sum is zero:

$$+0''.17, -0''.07, +0''.16, -0''.07, -0''.04, -0''.15.$$

Tests with Standard Electric Lamps: E. S. KING.

These tests relate to two lamps, rated for 2-candle power, loaned from the Bureau of Standards at Washington. In comparing these lamps with the Argand Standard, I have included 6 commercial lamps, which were regulated to approximately the same intensity. The results for 8 comparisons, made at intervals of about a day, show great constancy. The average deviation in magnitudes for Lamp No. 1 is ± 0.035 , for Lamp No. 2 ± 0.031 , for the mean of the 6 commercial lamps, ± 0.030 and for the mean of all the lamps ± 0.025 .

Comparisons with ten different stars were made by the out-of-focus method with the 11-inch Draper telescope on seven different nights. The resulting photographic magnitudes for the lamps at a distance of 1 meter are as follows: Lamp No. 1, 12.02; Lamp No. 2, 12.10; Lamp No. 8, 12.01. From the comparisons with the Argand the results are, Lamp No. 1, 12.05; Lamp No. 2, 12.12; Lamp No. 8, 12.04. These figures indicate that the lamps must be placed at a distance of about a kilometer to have the same photographic brightness as Polaris.

Recent Interviews with Optical Glass Manufacturers of France and Germany: J. A. BRASHEAR.
Some Observations with the 60-inch Reflecting

Telescope of the Mt. Wilson Solar Observatory:
E. E. BARNARD.

Photographic Observations of Brook's Comet 1911: E. E. BARNARD.

This comet when found by Brooks was a faint object without any tail. A long exposure photograph a few days after its discovery showed only a round diffused object with no signs of a tail. Later the comet developed a tail, and became visible to the naked eye and presented a splendid spectacle in the evening and then in the morning sky. Its naked eye visibility was of long duration, from August to December.

Though it developed a slender tail early in its career it was very disappointing, for photographs made night after night did not show any changes worth mentioning and the comet promised to be of little interest from a photographic standpoint. The photographs on different nights simply repeated themselves. In October, however, there was apparently a complete transformation of its nature and it really became one of the most interesting comets yet photographed. From the previous condition of a steady outflow of matter which marked its appearance until October the tail now presented a very active and remarkable appearance changing from day to day from one complex and beautiful form to another equally remarkable. The photographic activity was also greatly increased, much more, apparently, than its increase of light would account for. The phenomena of Morehouse's comet were duplicated in almost every particular. This change in the nature of Brook's comet did not seem to be due to any special change in its spectrum. Cyanogen did not appear at any time in the spectrum of the tail, though it was present in the head. This compound which was such a striking feature of the spectrum of the tail of Morehouse's comet was supposed to be the cause of the remarkable phenomena of that comet. Its absence from the tail of Brook's comet would seem to show that after all it was not necessarily the cause of the freakish nature of that comet.

Personal Equation Apparatus for Nine-inch Transit Circle, Naval Observatory: F. B. LITTELL.

The new personal equation apparatus recently installed is based on the same principle as that devised by Professor John R. Eastman, U.S.N., but differs entirely in details and secures a much more exact reproduction of the circumstances of actual observation and more extended application.

An artificial star moves alternately east and west across the line of sight at the focus of the

north meridian mark, a small electric motor furnishing the motive power. The speed can be varied to represent that of any star from 0° to 89° of declination. The apparent magnitude of the star may be varied by interposing screens in the line of sight, or by changing the resistance in the electric-light circuit.

This star will be observed by the use of the transit circle, just as an actual star would be observed, the movement of the carriage carrying the star in the meantime causing a similar automatic record to be registered on the chronograph. A complete observation includes the observation of the star during its east and west movement, using a reversing prism at the eyepiece to keep the apparent direction the same. By comparing the observer's record of such an observation with the automatic record, his absolute personal equation can be determined, and by suitable series of observations, the personal equations of various observers dependent on velocity and direction of motion, or magnitudes of stars, and for such objects as the limbs of the sun, moon, etc., may be determined.

At present nearly all star catalogues are more or less affected by such errors. Even if a self-registering right ascension micrometer and a reversing prism are used, by which many errors are greatly reduced, it is still desirable that observers should determine them, and if necessary apply corrections for them.

Measures of the Satellite of Neptune, and of Oberon and Titania, Satellites of Uranus, made at the Naval Observatory, 1908-10: ASAPE HALL.

After the publication, in 1875 and 1885, of the measures made at the Naval Observatory of the satellite of Neptune, Mr. Marth pointed out the curious motions of N and I , which determine the position of the satellite's orbit plane with reference to the equator. It has been explained that these motions might be produced by a flattening of the planet which causes the pole of the plane of the satellite's orbit to describe uniformly a small circle about the pole of the planet.

Therefore, for the purpose of following these motions, the satellite of Neptune has been measured at the Naval Observatory during many oppositions.

For the two oppositions 1908-09 and 1909-10, the following corrections have been obtained to the data of the *Connaissance des Temps*, which are the elements of H. Struve published in 1894:

1908-09	1909-10
$du = +1^{\circ}.223 \pm 0^{\circ}.190$	$du = +0^{\circ}.521 \pm 0^{\circ}.162$
$dN = +1.341 \pm 0.383$	$dN = +1.097 \pm 0.313$
$dI = +0.401 \pm 0.376$	$dI = -0.277 \pm 0.294$
$Q = 179^{\circ}.51$	$Q = 37^{\circ}.34$
$e = 0.002,71$	$e = 0.009,60$
$da = +0^{\circ}.844 \pm 0^{\circ}.056$	$da = +0^{\circ}.058 \pm 0^{\circ}.045$

The corrections to u , N and I are believed to be real. Evidently there is a considerable change of personal equation in the distance pointings, as has been shown already in the measures of several observers.

The measures of Neptune's satellite made some years ago at the Yerkes Observatory by Professor Barnard with the 40-inch refractor, give for the semi-major axis of the orbit at the mean distance of the planet from the sun, $16''.22$, instead of $16''.27$, which is usually accepted.

On account of the large aperture of the telescope employed, this determination appears to be the most accurate of the visual measures, and least liable to systematic errors.

Various experiments have been made at the Naval Observatory with reference to the elimination of systematic errors, including the use of reversing prisms. However, with the prisms employed, so much light is lost that they can be used only on very good nights.

For Oberon and Titania, satellites of Uranus, the following corrections have been obtained to the elements of the *Connaissance des Temps* from observations made at the oppositions of 1908, 1909, 1910:

Oberon	Titania
$du = +0^{\circ}.767 \pm 0^{\circ}.207$	$du = +1^{\circ}.340 \pm 0^{\circ}.262$
$dN = -0.077 \pm 0.360$	$dN = -0.634 \pm 0.474$
$dI = -0.611 \pm 0.347$	$dI = -0.730 \pm 0.412$
$Q = 218^{\circ}.41$	$Q = 216^{\circ}.45$
$e = 0.0100$	$e = 0.0934$

$da = +0^{\circ}.167 \pm 0^{\circ}.119$	$da = +0^{\circ}.139 \pm 0^{\circ}.090$
---	---

From measures secured in 1911 by Mr. Eppes and Mr. Burton, Mr. Eppes has found the following corrections to the data of the *Connaissance des Temps*:

Oberon	Titania
$du = +0^{\circ}.735 \pm 0^{\circ}.179$	$du = +1^{\circ}.778 \pm 0^{\circ}.159$
$dN = -0.263 \pm 0.261$	$dN = -0.253 \pm 0.295$
$dI = +0.221 \pm 0.235$	$dI = +0.083 \pm 0.271$
$Q = 60^{\circ}.06$	$Q = 285^{\circ}.02$
$e = 0.00214$	$e = 0.00180$
$da = +0^{\circ}.072 \pm 0^{\circ}.074$	$da = +0^{\circ}.208 \pm 0^{\circ}.075$

The Paris Conference of October, 1911: W. S. EICHELBERGER.

At the recent conference of the directors of the several national nautical almanacs held in Paris in October, 1911, cooperation among the respective offices was recommended to their several governments. A full account of the work of the conference is contained in the *Astronomische Nachrichten*, No. 4535, for November 12, and in *Nature* for November 30.

Attention was called particularly to three of the resolutions adopted by the conference.

1. The conference strongly recommends that the ephemerides of the stars, that is to say, their correction from mean to apparent place, should be calculated for the upper transit at the meridian of Greenwich.

2. The conference is of the opinion that the adoption of the meridian of Greenwich for all ephemerides should be realized as soon as possible.

3. The ordinary ephemerides of the stars shall be calculated to 0".001 in right ascension so far as 60° of declination and 0".01 in declination.

The first two resolutions quoted imply that each office in computing results which are to be furnished the other almanacs will do so for the Greenwich meridian. The question naturally arises with reference to the *American Ephemeris*, for instance:

1. Should the ephemerides for the physical observations of the sun, moon and planets and the ephemerides of the satellites of Mars, Uranus and Neptune which will be computed by the office of the *American Ephemeris* for Greenwich mean noon and in that form furnished to the other almanacs, be printed in our almanac for Greenwich mean noon, or is there sufficient reason to require us to make the necessary additional computations to enable us to publish these data for Washington mean noon as at present?

2. Should the apparent places of the stars which will be furnished to the office of the *American Ephemeris* by the European almanac offices for superior passage over the meridian of Greenwich be published in our almanac for transit at Greenwich or transformed to transit at Washington as at present?

3. Is it to the advantage of astronomers in general to have the apparent places of stars given to 0".001 in R.A. so far as 60° of declination and 0".01 in declination?

It is not intended to increase the labor of computing to obtain the additional decimal, but simply

to publish the additional decimal which is at present always computed in the various almanac offices. Nor is it intended that this last decimal shall be accurate to within a unit. In fact it may be in error several units. The object in publishing the additional decimal is to permit any one to interpolate to the time of observation, the apparent place as given; to apply the short period terms for whose calculation convenient tables will be provided; and finally to obtain his computed right ascension at the time of observation accurately to the hundredth of a second of time and his declination to the tenth of a second of arc.

It is upon these questions that the Naval Observatory would like to have an expression of opinion from the astronomers of the country.

The Spectrum and Orbit of β Scorpii: Z. DANIEL and F. SCHLESINGER.

This is one of the spectroscopic binaries (discovered by Slipher at the Lowell Observatory) for which the H and K lines, due to calcium, appear to be nearly or quite stationary. Only two of these objects have thus far been studied: δ -Orionis by Hartmann and α -Persei by Jordan. From 73 spectrograms secured in 1911 with the Mellon spectrograph of the Allegheny Observatory, the following elements have been derived by means of a least-squares solution.

$$\begin{aligned} P &= 6.8283 \text{ days} \pm 0.0001 \text{ day,} \\ K &= 125.66 \text{ km.} \pm 1.18 \text{ km.,} \\ e &= 0.270 \pm 0.008, \\ T &= \text{J.D. } 2419163.923 \text{ G.M.T.} \pm 0.034 \text{ day,} \\ \omega &= +20^\circ.1 \pm 2^\circ.2, \\ \gamma &= -11.0 \text{ km.} \end{aligned}$$

Measurements of the secondary spectrum could also be made on some plates, and these yield

$$\begin{aligned} K_s &= 197 \text{ km.} \pm 10.5 \text{ km.,} \\ m \cdot \sin^3 i &= 13.0, \\ m_s \cdot \sin^3 i &= 8.3, \end{aligned}$$

the unit of mass being that of the sun. Using Rowland's wave-length for the K-line, the mean velocity derived from it is $-8.6 \text{ km.} \pm 1.7 \text{ km.}$, which is not far from that of the center of mass of the system, a result in accord with those for δ Orionis and α Persei.

Report of the Committee on Comets, December, 1911: G. C. COMSTOCK (chairman).

Owing to the absence of its chairman abroad during a major portion of the past year the work of the committee on comets has consisted mainly

in the accumulation and tabulation of replies to its circular letter relative to photographs of Halley's comet. From these replies there has been constructed a card catalogue exhibiting in chronological order the material available for a photographic history of this comet during its appearance of 1910. At present this catalogue consists of about a thousand titles, but it can not be regarded as complete, owing to the absence of reports from several important sources.

Correspondence is being conducted in the endeavor to supply as far as may be the missing data, but it is already apparent that the existing gaps can not be completely filled. A period of very great activity in photographing the comet accompanies the date of its nearest approach to the earth, but this is preceded by an epoch of comparative neglect and is followed, in July, 1910, by an apparently complete cessation of photographic work upon the comet, continuing until December, when some exposures were made at the Lick Observatory and reported to the committee. It is earnestly hoped that these lacunæ will be filled by observations not yet reported to the committee.

As soon as the card catalogue can be regarded as reasonably complete it is the purpose of your committee to select from it such data for reproduction as will best serve its purpose of constructing a graphic history of the comet's appearance in the years 1909-10.

Report of the Committee on Photographic Astronomy: F. SCHLESINGER (chairman).

The chairman reported briefly on the progress made since the meeting at Ottawa four months earlier, at which a full report had been read. It appears that the most immediate duty of this committee is to study the movements of a pier during the course of a night, and if possible to devise some method by which a pier can be kept stationary within small amounts. For this purpose a 10-inch photographic telescope of 100 inches focal length has been constructed, and is now being mounted upon a pier at the Allegheny Observatory. The pier and telescope are to be kept at a nearly constant temperature in a basement room at the observatory. At frequent intervals throughout the night, short exposures are to be made upon the region of the pole, access to this part of the sky being obtained through a window of plane parallel glass. Dr. Schlesinger also referred briefly to the progress made by Dr. Ross with the photographic zenith-tube designed by the latter and mounted by

him at the International Latitude Station at Gaithersburg. The material thus far secured indicates a considerable reduction in accidental errors, as compared with the best work of the zenith telescope by Talcott's method. This instrument had been in operation during a few months only, and consequently no information is as yet forthcoming as to the freedom of the method from systematic error.

A verbal report by Professor C. L. Doolittle, chairman of the committee on cooperation in the teaching of astronomy, was followed by an extended and profitable discussion.

Late in the afternoon of Friday, December 29, the society adjourned to reassemble at the Allegheny Observatory, Pittsburgh, in the following August.

R. H. CURTISS,
Editor for the Meeting

ANN ARBOR,
February, 1912

SOCIETIES AND ACADEMIES

THE ACADEMY OF SCIENCE OF ST. LOUIS

THE meeting of the Academy of Science of St. Louis was held at the Academy building on Monday, March 18, 1912, at 8 P.M., President Engler in the chair.

Professor C. A. Waldo, of Washington University, addressed the academy on "The Problems of Coal Exhaustion."

"Miniature Flint Arrows" was the subject of a short paper by Dr. H. M. Whelpley, who illustrated his remarks with over 2,000 specimens, varying in length from .06 to 1 inch. In form they represent all of the common types of ordinary arrows and were evidently made by the same process of pressure chipping. Specimens have been found in England, Spain, Belgium, India, Palestine, Egypt and the United States. These artifacts belong to the Neolithic age. It has been suggested, but without evidence, that they were made by a pygmy race of human beings. It is also claimed that they were barbs for harpoons, tattooing instruments, fish snags or drills for skin and shell work. Dr. Whelpley concludes that the medium size and larger miniature arrows, such as are very plentiful along portions of the Missouri and Meramec Rivers, were used as arrow heads. The most minute ones he considers examples of skill in flint chipping, the same as the miniature baskets made by the Pomo Indians to-day are merely examples of skill in basketry.

Dr. R. J. Terry reported on "A Grove of Deformed Trees."

A grove of four or five hundred small persimmon trees in St. Louis County has suffered from the ravages of a beetle which has been identified as *Oncideres cingulata*. Limbs varying in diameter from 5 to 15 mm. are girdled and the ends fall to the ground. All the trees, old and young, have been attacked. The girdling is done in the fall, mainly in September and October. During this time the larger trees present scores of branches bearing dead leaves and the ground is strewn with fallen branches often laden with fruit. There is no tree in the grove that does not present crooked trunk and limbs. The deformities in some cases are extreme. Most of the trees are as a consequence dwarfed, although able to make some advance in growth. Some trees only a meter and half tall bore fruit in 1911.

A few beetles have been observed working. The cut was begun on the upper side of the branch and was made 3-4 mm. wide and about 3 mm. deep. Most of the limbs fall, probably within a few days after the girdling. A small proportion remain throughout the following winter. On every severed branch, near the distal ends of the twigs, one or more small deep excoriations of the bark were found. That the beetle makes similar abrasions of the bark of twigs of the honey locust is known from observation on *Oncideres* in captivity. Limbs recovered from the ground in winter in some cases presented no evidence of the propagation of the beetle, whereas in others more or less of the wood had been destroyed under the bark along one side of the branch extending from the distal end proximally. The cavity never quite reached the proximal severed end. Larvæ which are now being studied were discovered in some of the tunnels.

At the meeting of the Academy of Science of St. Louis, held at the Academy building, March 4, 1912, Dr. Charles A. Todd addressed the academy on "A Problematical Geological Phenomenon in Colorado."

In the Estes Park district of Colorado there is a remarkable collection or aggregation of rocks, the exact nature of which at present is undetermined. This geological puzzle is in the form of an oblong pit with sides sloping at an angle of 45° and meeting at the bottom. Its length is 600 feet; width, 200; depth, 50. These measurements are only estimates. At the eastern extremity of this oblong is a circular pit 150 feet in diameter.

Both pits have the same general characteristics. Their walls are of more or less cubical masses of country granite, sharp angled and solidly jammed together for the most part. The largest blocks are on the upper part of the wall; one I judged to be 30 × 40 feet with irregular thickness. These pits are in the valley of Fern Lake on a branch of the Thompson River and about three miles from the Continental Divide. They are on the right-hand side of Fern Lake, forming part of the shore. All this district has been subject to glacial action and this valley gives all indication of having been plowed out by the ice. Fern Lake is a circular glacial lakelet about one fourth of a mile in diameter and said to be 75 feet deep. Its shores drop off abruptly with the depths. Just above the lake is a bench extending two miles up stream to another and larger glacial lake. At the lower end of Fern Lake is a terminal moraine, filling the valley (which is here about three fourths of a mile wide) and extending down stream two miles, where the main Thompson flows through a rather wide cañon. The question is, how came these rocks here and so arranged. Two theories are advanced: One is that the pits represent a "blow-out." In that case the applied force must have been gaseous, since there is no lava or ash in the neighborhood. The second theory is that the rocks are glacial deposit. They are, as stated, in the course of the ice stream and next an extensive moraine. But the peculiar configuration of the pits, the sharp angles of the cubical fragments, etc., seem to oppose this view. The surest way to settle the matter evidently would be to sink a shaft in the bottom of the main pit and determine whether or not the broken rock extends well below the general level of the valley at that point.

Dr. H. T. A. Hus, of the University of Michigan, read a paper on "Inheritance in *Capsella*."

Professor Nipher made a verbal communication concerning some of his more recent work on the nature of the electric discharge. Former results of his work seem to point very strongly to the one-fluid theory. It would follow that the two waves which were shown to exist in the Wheatstone experiment were compression and rarefaction waves. The negative wave is in the nature of a supercharge which travels along on the outer surface of a thin outer film of the conductor. The positive wave is one in which a thin outer film of the wave is suddenly drained of the negative charge, at the instant of passing of the wave. We had been led to suspect as a result of recent experiments that

matter in this latter condition is explosive. The tests have been made on thin fuse wires sealed into long glass tubes through which the wire passes. The wires were sealed in by means of hard sealing wax. A discharge from a battery of Leyden jars was passed through the wires. The disintegration of the wires is much greatest at the positive end. The sealing wax, wire and glass tube in almost every case, break down at that end. The lead is dispersed in a fine powder or dust.

Professor Nipher remarked that he had just found in the London *Phil. Mag.*, Vol. 46, of 1815, pp. 161 and 259, an account of the work of De Nelis and Singer, who passed a positive discharge through a lead wire of 0.01 inch diameter contained in an iron tube. The wall of the tube was usually about 0.14 inch in thickness. In one case the tube was one inch in external diameter, with a small bore admitting a steel needle with wax insulation and terminating in the short lead wire resting on the bottom. The lead wire was surrounded by oil. Such tubes were burst by repeated explosions of the lead wire, which required to be replaced at each discharge. The discharge was from a battery of Leyden jars having an area of from 75 to 100 square feet. The needle and part of the liquid were thrown out at each explosion. In some cases the liquid was thrown to a height of 40 feet. The experimenters do not seem to have used the negative discharge. They attributed the effects to the expansive power of the electric fluid.

What they were doing was to suddenly drain that lead wire of the negative fluid. The atoms of lead then repel each other. Some of the effect is of course a heat effect. The question arises, however, will the negative discharge produce a like or an equal effect? Is it not possible that such molecular repulsion is primarily concerned in the formation of disruptive channels in air and resulting in spark discharges and lightning?

GEORGE T. MOORE,
Corresponding Secretary

THE BOTANICAL SOCIETY OF WASHINGTON

THE 79th regular meeting of the society was held at the Shoreham Hotel, Tuesday, March 5, 1912, at 8 o'clock P.M. President W. A. Orton presided. This being the annual open meeting the program was devoted to an address on "The Present Status of the Genetics Problem," by the retiring president, Professor W. J. Spillman. The address will appear in *SCIENCE*.

THE 80th regular meeting was held at the Cosmos Club, Tuesday, April 2, 1912, at 8 o'clock P.M. President W. A. Orton presided. Eighteen members were present. Dr. Errett Wallace and Messrs. L. H. Evans, S. M. McMurren and S. C. Stuntz were admitted to membership.

The following papers were read:

Studies on European Herbaria with Special Reference to Preservation of Type Specimens: WALTER T. SWINGLE.

The speaker on recent visits to the principal European herbaria was impressed by their lack of the geographic limitations, so common in American herbaria. However, the management is much the same as it was a century ago. There is no adequate correlation of the seed and fruit collections with the plants in the herbaria. Alcoholic specimens scarcely exist, and such as are found are neither well indexed nor referred to on the specimen sheets.

The method generally followed at present of leaving types along with the other specimens is certain to lead to their rapid deterioration and ultimate loss. Provision should be made for saving fragments which may drop from the specimen and to this end it was suggested that a sheet of transparent paper be pasted to the back of the herbarium sheet, bending over it, thereby protecting the specimen. Smaller types and fragments of types can be preserved in pasteboard boxes with a glass top, the specimens being pressed against the glass by layers of cotton batting.

It is important to recognize that in plants type specimens can often be indefinitely multiplied by cutting branches from the same plant, or by securing flowers or fruits from the same plant during successive years. These types which are secured from the same plant individual are termed *merotypes*.

The Celebration of the One Hundredth Anniversary of the Academy of Natural Sciences of Philadelphia: W. E. SAFFORD.

Mr. Safford, the delegate of the Botanical Society at the academy's centenary celebration, gave a graphic and comprehensive report of the meetings and made special mention of the papers of botanical interest there presented. The speaker also gave an account of the development and resources of the academy's herbarium.

THE FUNGUS OF THE CHESTNUT-TREE BLIGHT¹

THE disease of chestnut trees now causing serious injury in the eastern states was first noticed about the year 1904 in the vicinity of New York and is believed to be due to the growth of a hitherto unknown fungus described by Murrill in 1906 under the name of *Diaporthe parasitica*. The question naturally arises: Is the *Diaporthe* a native species of this country which had escaped the observation of mycologists, or is it an introduced exotic species? If it is a native species we must next ask how it happens that so severe an epidemic has appeared suddenly, for, if the fungus has always existed here, the important practical question is: What temporary conditions have arisen which have enabled it to increase at a rate previously unknown? Although there are some vague references to diseased chestnut trees in agricultural journals published a good many years ago, there is nothing in them to warrant us in believing that a disease at all comparable with the present chestnut epidemic ever prevailed here. One thing, at least, is certain. Had there been within the last fifty or sixty years a disease of chestnuts in the region now devastated similar to the present epidemic, there would have been left no large trees to be attacked now.

In general it may be said that when a disease due to a fungus appears suddenly and with great severity, the chances are that it is owing to the introduction of some exotic species which, although it may not

¹ Paper read April 19, 1912, before the American Philosophical Society, Philadelphia.

cause serious trouble in the country from which it came, is able to produce disastrous effects on our native species which have not through long exposure become more or less immune to the fungus. It has been suggested that the chestnut-tree fungus was introduced from Japan. The arguments advanced by those who adopt this view do not seem to me to be at all conclusive. That the *Diaporthe parasitica* is a native of Japan remains to be proved. Furthermore, we have no accounts of any disease of chestnuts in Japan similar to our present disease. If I am not mistaken, the main reason for thinking that the disease might have come from Japan was the statement which had been made that Japanese chestnuts grown in this country did not contract the disease. That they are really immune is, to say the least, very doubtful, and is positively denied by some experimenters.

The first fruiting specimens of the chestnut-blight fungus which I was able to examine struck me as having a close resemblance externally to what is generally known in American herbaria as *Endothia gyrosa* and also to a specimen issued in an Italian series of fungi exsiccati. With regard to the North American specimens of *Endothia* I shall speak later. The Italian specimen to which I refer is No. 986 of the first series of the *Erbario Crittogamico Italiano* issued in 1863. The label states that the fungus grew on chestnut trunks at Locarno on Lake Maggiore, where it was collected by Daldini in 1862. The name there given is *Endothia radicalis*, on which more needs to be said in connection with American specimens. The Italian specimen referred to has ascospores which seem to me to be the same as those of American specimens of *Diaporthe parasitica*, and my opinion is shared by some other mycologists who have examined the specimens in

question. Of European botanists who have expressed the opinion that *Diaporthe parasitica* and *Endothia gyrosa* are identical may be mentioned Von Höhnelt and Saccardo.

But the Italian fungus, by whatever name we call it, is not known to cause a disease of chestnuts in Italy, where, in consequence of the commercial value of the chestnut, the fungi which attack it have been carefully studied. Several diseases of chestnuts, due to fungi, are known in Italy, but the fungi which cause them are not any form of *Endothia*. In spite of the fact that the *Endothia* does not cause a recognized disease in Italy, it is conceivable that, if introduced into this country, it might cause serious damage to American species of chestnuts, since they have not by long exposure to the fungus become immune.

In this connection it should be stated that the Italian chestnut trees cultivated in this country are said to be attacked and destroyed by *Diaporthe parasitica* as well as our native species of chestnuts. We have also some recent experiments of Pantanelli, who in the *Rendiconti Accademia dei Lincei* of 1911 gave an account of inoculations made at Rome with spores of *Diaporthe parasitica* received from America. He made three sets of experiments. In one he inoculated sterilized dead branches of the Italian chestnut; in another living branches kept in closed cultures, and in the third he inoculated small chestnut trees placed in dishes in his laboratory. From the first two series of experiments, although the spores of the American material germinated, and developed a mycelium and conidia, we can infer only that the fungus in closed cultures may be made to grow as a saprophyte on the Italian chestnut, but we can infer nothing as to its parasitic action. In the third series of

experiments Pantanelli inoculated sixteen plants. Of these seven dried up, whether from the action of the fungus or from some other cause is not quite clear. From the other cases Pantanelli concludes that the American fungus may cause serious damage to Italian as well as American chestnuts. No control plants appear to have been used. To obtain a clear idea of the action of the fungus a more detailed account is to be desired.

Pantanelli compares the American *Diaporthe parasitica* with the five other species of *Diaporthe* which have been recorded on chestnuts and he considers it different from any of them, in which opinion he is correct. The important point, however, is not to distinguish between *Diaporthe parasitica* and the other five species of that genus, but between *Diaporthe parasitica* of America and *Endothia radicales* of northern Italy, to which it is evidently more closely related than to any of the other *Diaporthe* species. It is also to be desired that series of experiments with the inoculation of the spores of the Italian *Endothia* on Italian and American species of chestnut be made.

Before proceeding farther let me recapitulate what has already been said. First, our chestnut-blight fungus, if an imported species, is not likely to have come from Japan. Secondly, a fungus noticed on chestnuts in Italy as long ago as 1862 in external appearance and the microscopic characters of the perithecia, asci and spores so closely resembles the American chestnut fungus that they have been considered identical by some well-known European botanists. Thirdly, the American fungus is believed to be the cause of a very serious disease of American chestnuts and also to attack Italian chestnuts grown in America, while, on the other hand, the Italian fungus does not produce any clearly recognized disease.

If we now turn to the question whether the fungus of the present chestnut blight can be considered identical with any species previously known in America, we find ourselves involved in a maze of conflicting descriptive and bibliographical details which must utterly confuse those who are not expert mycological systematists, and even experts may be pardoned if they hesitate to express a very decided opinion on the subject. Although it can not be expected that any but specialists would be interested in the study of the very scattered literature relating to the subject, it may be of interest to others to have a general statement as to why it is so confusing even to experts.

As has been said, the name on the label of the specimen in the Erbario Crittogamico Italiano is *Endothia radicalis*, which to mycologists signifies that the Italian botanists, Cesati and De Notaris, to whom the naming of the specimen is to be attributed, were of the opinion that the Italian fungus was not a new species, but was identical with *Sphaeria radicalis* of Schweinitz described in his "North American Fungi" in 1832, which they erroneously quote as the species on which Fries founded the genus *Endothia* in 1849. The genus was really founded on *Sphaeria gyrosa* of Schweinitz from North Carolina, described still earlier, in 1822. Subsequent writers, however, considered *S. gyrosa* and *S. radicalis* as the same species to which the earlier specific name *gyrosa* should be given. Besides the specimen issued in the *Erbario Crittogamico* other Italian specimens were distributed in Rabenhorst's "Herbarium Mycologicum," Thuemen's "Mycotheca Universalis" and Saccardo's "Mycotheca Veneta," and as early as 1829, only seven years after Schweinitz's original description, *Sphaeria gyrosa* was reported in Italy by Rudolphi in *Linnaea*.

Since 1829 there have been numerous references to the same fungus occurring in other European countries. In 1830 Fries stated in *Linnaea* that it had been found in France, and Tulasne in his "Carpologia," 1863, refers in detail to French specimens. In 1870 Fuckel and in 1886 Winter referred to its occurrence in Germany and specimens were distributed by Roumeguère in "Fungi Gallici" and Portuguese specimens in "Fungi Lusitanici." In the recent "Flora Italica Cryptogama," 1906, the species is said by Traverso to occur in still more remote regions. If we are to trust the writers above mentioned *Endothia gyrosa*, originally described from North Carolina, is a species which is widely scattered through the northern hemisphere. It is generally said to grow on dead wood and in no cases is there any mention of a serious disease of the trees attacked. The hosts mentioned are, besides *Castanea*, *Æsculus*, *Alnus*, *Carpinus*, *Corylus*, *Fagus*, *Juglans* and *Quercus*.

Although, assuming that *Endothia gyrosa* and *Endothia radicalis* are only different names for a single species, all the European mycologists mentioned agree in believing that their *Endothia* on chestnuts is identical with the *Endothia gyrosa* of North America, we must ask ourselves whether their opinion is correct. This brings us to the main question, or rather conundrum: What is *Endothia gyrosa*? If we could answer that question most of the systematic difficulties which perplex us would disappear. Unfortunately, it seems to be almost impossible to be sure of what Schweinitz included under his *Sphæria gyrosa*. Specimens are in the Schweinitzian Herbarium in the Academy of Natural Sciences in Philadelphia, and other specimens of Schweinitz are to be found in a number of other herbaria in this country and Europe. Through the kindness of

Professor Stewardson Brown I have been able to examine the specimens in the academy's collection and I have also examined Schweinitzian specimens in some other herbaria and have obtained information from others who have examined specimens which I have not seen. All the specimens I have seen agree in external appearance, the fungus looking to the naked eye like brownish-orange, pustulate cushions usually growing in cracks in the bark. Unfortunately, microscopic examination does not show ascospores, which are necessary to distinguish the species with accuracy. In American herbaria one sees many specimens marked *Endothia gyrosa* by different collectors, but almost always what was said of Schweinitzian specimens applies to these, viz., they show no ascospores. The same is true of the specimens distributed in European exsiccata with the exception of the No. 986 of the *Erbario Crittogamico*. The problem is to find undoubted Schweinitzian specimens with ascospores and here one must be careful to distinguish between what may be and what certainly are Schweinitzian specimens. I have not finished my search, but from my experience up to the present time it looks as if it were doubtful whether good Schweinitzian specimens with ascospores can be found. Others, however, may be more successful, but since Schweinitz himself did not make use of microscopic characters it is hardly worth while to spend much more time in discussing what he understood by *Sphæria gyrosa*, since it is now known that there are at least two species in this country which in gross appearance resemble *Sphæria gyrosa*, but which differ in the size and shape of the ascospores.

Unless we can obtain more information than has yet been possible, it will be better to consider that the authority for the genus *Endothia* should be Fries, emended by

Cesati and De Notaris, who in their "Sferiacei Italici," 1863, gave a sufficiently detailed and accurate description of *Endothia radicalis* with a recognizable figure, so that, taken in connection with the specimen in the *Erbario Crittogamico*, there can be no doubt as to what they understood by the species. This may or may not be the same as the *Sphaeria radicalis* of Schweinitz, but certainly no genuine Schweinitzian specimens which I have ever seen would warrant any one in expressing a definite opinion. As far as one can distinguish species by their morphological, apart from their pathogenic, characters, *Diaporthe parasitica* seems to me to resemble the Italian *Endothia radicalis* so closely that they can not be separated specifically unless it be by some peculiarity not hitherto recorded.

There is still another point which should be considered. Is the fungus of our chestnut blight ever found on other trees? I have received a series of interesting specimens collected by Professor G. P. Clinton, which will illustrate this point. In some the bark of chestnuts and in others the bark of oaks is infested with an *Endothia* which in general appearance and in microscopic structure seem to me to be the same species. It is not, however, true that all the *Endothia* which occur on oaks belong to this species. There is an *Endothia* which appears to be common on oaks in the south, especially Florida and Louisiana, of which I collected material myself in New Orleans, which is clearly distinct from the *Endothia* of chestnuts, having ascospores much narrower and of a shape more nearly linear or bacilloid. Schweinitz gave as hosts of his *Sphaeria gyrosa* *Fagus* and *Juglans*, and of *Sphaeria radicalis* the exposed roots of *Fagus*. Too much weight, however, should not be placed on the hosts given by Schweinitz, for an examination of fungi of

different kinds collected by him shows that in his statements as to the hosts he was not always to be trusted.

The generic position of the chestnut fungus is of interest only to mycologists. It has been placed by Rehm in the genus *Valsonectria* and by Von Hoehnel in *Endothia*. If we accept the distinction between the Hypocreales and the Sphaeriales as generally understood, then *Diaporthe parasitica* should be placed in the former and removed from *Diaporthe* proper, which belongs to the Sphaeriales. The distinctions between the two groups, it must be confessed, are rather arbitrary in a more natural system, and the valsoid genera of both groups might be put together. But the present condition of mycology does not admit the formulation of a truly natural grouping of genera. If, as I think, *Endothia* should be kept as a genus, then *Diaporthe* should be placed in that genus rather than in *Valsonectria*, which was not created until years later. Furthermore, even if *Diaporthe parasitica* be considered a true *Diaporthe*, the name *Endothia*, it should be remembered, antedates *Diaporthe* of Nitzschke.

In conclusion it may be said that the chestnut-blight fungus suggests a number of important and difficult questions to mycologists. A definite answer to some of them might throw some light on the possibilities of checking the disease, but wherever it may have come from, whether native or exotic, what we now know of its life history unfortunately gives us no reason to suppose that it could be seriously checked, much less extirpated, by any means which could be generally adopted, although something might be attempted where it is desired to protect special limited areas. At present it is the mycologist rather than the forester who is called on to investigate. From what has been said the

following problems remain to be solved. What is the relation of our chestnut-blight fungus to the *Endothia* on chestnuts in Italy? What species related to or identical with the chestnut fungus grow on other trees in this country, and how do they affect such trees? Is it possible to determine authoritatively whether *Sphaeria gyrosa* and *Sphaeria radicalis* Schweinitz are identical or distinct species, and are European botanists justified in believing that the *Endothia* of Europe is identical with either of the species of Schweinitz? Some of these questions mycologists may be expected to answer hereafter. Others may never be answered except by those in whom the power of observation does not exclude the exercise of a vivid imagination.

W. G. FARLOW

MORE TROUBLE FOR THE SYSTEMATIST¹

ON a former occasion, in an address as retiring chairman of Section F of the American Association for the Advancement of Science, your speaker had occasion to bid for the sympathy of his zoological colleagues, the immediate cause of distress being a prediction on the part of Dr. C. B. Davenport that "the future systematic work will look less like a dictionary and more like a table of logarithms."

In the ten years that have passed since that time, this particular specter has not reappeared, and the systematists have placidly gone on their way, apparently oblivious to the existence of logarithmic functions. This, however, may be due to their general belatedness and ultra conservatism; and it is not impossible that the threat of Dr. Davenport may still disturb the placidity of their dreams.

There are other troubles, however, that have arisen in the meanwhile, that are not a whit less disturbing than the one just mentioned.

A serious and most important effort to meet

some of the difficulties of nomenclature has been made in the formation of the International Commission on Zoological Nomenclature, a thoroughly dignified and able body of zoologists, of which Dr. C. W. Stiles is the accomplished secretary and most influential American member. In the formation of this commission great pains were taken to make it truly international and representative. It was formally appointed by the most dignified body of zoologists in the world, the International Zoological Congress, and has striven earnestly and faithfully to perform its herculean task. It has been confronted with almost unsurmountable obstacles, and is certainly deserving of praise for its efficiency and courage.

That this commission would meet with serious difficulties was to have been predicted. In the attempt to formulate general laws it is inevitable that there should result individual cases of hardship and injustice, particularly when the law is inflexibly administered. Zoologists, like other men, are apt to be more or less restive under restraint, and consistency in applying the law of priority enacted by the International Commission was bound to involve irritating consequences.

These consequences are felt not only by the relatively small number of systematists, but even more keenly by the morphologists, embryologists and others who have to use zoological names, although they are spared the pains of making them, and are much inclined to cling fondly to those which have been rendered familiar by usage.

These men are naturally exasperated when they are required to call a holothurian a "bohadschioidean," and find it hard to recognize an actinian under the guise of "Dagyside."

Systematists have always, however, been subject to the execrations of their fellow zoologists along these lines, and at times deservedly so. It is inevitable, on the one hand, that classifications and hence names must change with the increase of knowledge and, on the other hand, it is equally certain that pedantic systematists and hair-splitting pur-

¹ Read before the Central Section of the American Society of Zoologists, at Urbana, Ill., on April 5, 1912.

ists will arise and, with more zeal than judgment, create havoc with existing and revered classification. These men have no exemption from the common quota of error which afflicts mankind in general, but their mistakes are apt to be more than ordinarily disturbing. There is such a thing as excessive pedantry in every class of students, as there are men who crucify the spirit of the law in order to maintain the letter.

But, to return to the International Committee on Zoological Nomenclature, it must be conceded that it has unraveled skillfully and patiently many knotty problems in nomenclature, and has performed a function which is surely an important one.

But it has aroused a more or less active spirit of opposition by its strict application of the priority law, a rule that is at the very foundation of many of its decisions. This law reads as follows:

Art. 25. The valid name of a genus or species can be only that name under which it was first designated on the condition (*a*) that this name was published and accompanied by an indication, or a definition, or a description; and (*b*) that the author has applied the principles of binary nomenclature.

While there have been individual zoologists who have vigorously objected to the rigid enforcement of the priority rule, it remained for the Scandinavian and Finnish zoologists to make the first formal and organized protest. There was published in the *Annals and Magazine of Natural History* for December, 1911, an article entitled "A Vote against the Strict Application of the Priority Rule in Zoological Nomenclature, with an Introduction by Dr. Th. Mortensen."

This introduction is interesting reading for the insurgents. It reviews the efforts that have been made to induce the International Commission to agree to the recommendation that "certain very commonly used zoological names should be excepted from the law of priority," and states that the Commission on Zoological Nomenclature has shown no inclination to accept the recommendation, claiming that such a desire for exceptions to the

rule is not indicated by any great number of zoologists.

It seems that there was published in the number of the *Annals and Magazine of Natural History* for December, 1910, a portion of an advanced copy of the Report of the International Commission in which the commission invites all zoologists to send in, prior to November 1, 1910, a list of 100 zoological names. All systematists are invited, moreover, to send a separate list of 50 or 100 generic names in their specialty which they look upon as most important and most generally used, each name to be accompanied by the full and complete bibliographic reference, by the name of the type species and the name of the order and family to which the genus belongs.

This proposition Dr. Mortensen regards as "not very far from an absurdity." Perhaps this language is too strong to apply to a request from the International Commission on Zoological Names; but it is nevertheless exceedingly frank. It would be interesting, moreover, to know how many systematists there are in this body who are so situated that they could drop their ordinary work and supply, on short notice, such a list, with proper bibliographic references.

Dr. Mortensen, with the help of some of his colleagues, secured a vote from 122 professional zoologists in Scandinavia and Finland, and found that all but two of them were ready to sign the following statement:

The undersigned Scandinavian and Finnish zoologists protest against the strict application of the law of priority in all cases, and express the desire that the most important and generally used names should be protected against any change on nomenclatorial grounds.

The names and official positions of the signers are appended. Dr. Mortensen concludes as follows:

It is to be hoped that the zoologists of other countries will follow the example given here. When this has been done, and it has been definitely proved that the great majority object to the strict application of the priority rule, it may perhaps be expected that the tyranny of that notorious law, which has already done so much harm to

science, will be thrown off; and then, perhaps, the International Commission will see that it is rather its duty to arrange for the codification of the desired names in accordance with the wishes of the zoologists.

Upon looking up all of the evidence at hand, and also communicating directly with the secretary of the International Commission, I am forced to the conclusion that there is no disposition on the part of that commission to except any names whatever from the mandate of the priority rule.

It should be said here that prior to the protest from the Scandinavian and Finnish zoologists, the British Association and the American Society of Zoologists had recommended "that certain very commonly used zoological names should be excepted from the law of priority," and, aside from these formal actions there has been developed a considerable amount of individual hostility to the strict application of the law; and in some cases there is open revolt.

The practical working systematist is now confronted with a very serious and perplexing dilemma. He is forced to ask himself which of two courses he should pursue. Shall he adopt the ruling of the commission and adhere strictly to the law of priority, in which he will not be followed by a large and important class of his colleagues? Or, shall he use his judgment in each particular case which comes up for decision, and thus bring down upon himself and his work the criticism of another important class and have both condemned by the International Commission on Zoological Nomenclature, a body created by the International Congress, and having plenary powers to enforce this rule? And it must be remembered that a large number of active systematists are thoroughly in accord with the commission.

It surely seems as if the systematist here finds himself placed squarely between the Devil and the deep sea. It is, of course, not within the province of this paper to designate which is which.

Now it must be confessed that there is much to be said in favor of the attitude taken by

the commission in this matter. In the first place, there is great virtue in a clear-cut and definite law, one without any "ifs" nor "ands" about it; and this advantage is undoubtedly possessed by the law in question. And it is clearly to the advantage of the commission, as court of last resort, to have such a rule at its back. A law of this kind is administered with much more facility than a looser one, and the consistent administration of such a rule can bring no efficient criticism upon the commission, *provided* that the priority rule has been legally enacted!

As a matter of fact, the International Congress of Zoologists, although perhaps not a strictly legal body, is presumably the most thoroughly representative, indeed the only international body of zoologists in a broad sense, that exists, or has existed.

This body formally adopted the code, as formulated by the duly authorized International Commission on Zoological Nomenclature, at the Berlin meeting, in 1901. The commission itself was formally appointed in 1895 at the Leyden meeting.

Further amendments were submitted by the commission, and adopted by the International Congress at the Boston meeting in 1907. Meanwhile a number of zoologists expressed the wish that the commission serve as a court for the interpretation of the code, and it has consented to act in that capacity.

A careful review of the records and history of the commission has forced upon the writer the conviction that the priority rule has as thorough a sanction in law as can be given by the International Congress of Zoologists, and that there is nothing in the records which authorizes the commission to deviate from that law. Moreover, it appears that the commission is correct in declaring that it "has no legislative power," and it is difficult to see how it could assume the right to practically amend the priority rule.

If ordinary parliamentary usages are to be followed, it seems to be plainly indicated that the only power that can amend or abolish this rule is the International Congress itself, either on its own motion, or in response to a recom-

mendation of the International Commission. But the congress itself has decreed that "no proposition for change in the code is permitted to come before the congress unless it is presented to the Permanent Commission at least one year before the meeting of the congress."

A letter from Dr. Stiles, the secretary of the commission, informs me that the congress has gone on record to the effect that it demands "a unanimous vote of the commission before any matter will be considered by the congress."

It is interesting to speculate at this point whether there is any conceivable method by which a dignified body of scientists could more completely and finally tie its own hands than the one here solemnly consummated by the International Congress of Zoologists. The method, in brief, is as follows:

1. Appoint a commission with power to formulate a code.
2. Formally adopt that code.
3. Forbid any amendment to be introduced except through the commission.
4. Declare that nothing will be considered unless brought before the congress with the unanimous vote of the commission.

I submit, most respectfully, that nothing more perfect of its kind has every been perpetrated by any political machine or autocrat.

All that the commission has to do is to "stand pat." The congress has done the rest.

C. C. NUTTING

HENRY JAMES CLARK: TEACHER AND INVESTIGATOR¹

HENRY JAMES CLARK, or H. James-Clark as he often wrote his name, sometimes called, not inaptly, the first professor of natural history at this college, was the first trained zoologist to occupy a chair here. But hardly had he

¹An address delivered at the dedication of the building for entomology and zoology at the Massachusetts Agricultural College, November 11, 1910. In the preparation of this sketch I am indebted to Dr. Edward S. Morse and Professor A. E. Verrill for much valuable information.

entered upon its duties when he was called from this life in the flower of his age.

Born at Easton, Massachusetts, on the twenty-second of June, 1826, the son of a clergyman, his father moved to Brooklyn, N. Y., where he lived many years and where the son received much of his early training and was fitted for college. After completing his preparatory studies, he entered the University of the City of New York, and was graduated thence in 1848. From college he went as a teacher to White Plains, and while engaged in the study of botany, made observations upon the structure of *Chimaphila* and *Mimulus*, which he communicated to Dr. Gray. These and subsequent observations upon the flora of the neighborhood attracted to him the favorable notice of the latter, who invited him to Cambridge. Thither he went in 1850, and enjoyed for a time the advantages of a pupil and private assistant at the botanic garden. While a student there he taught, for a single term, the academy at Westfield, achieving much success as a teacher. Soon after this a taste for zoological studies, developed by the lectures of Professor Agassiz and frequent visits to the zoological laboratory, led him to abandon botany for what appeared the more fascinating study of animal life. Graduating from the Lawrence Scientific School in 1854, he became immediately after the private assistant of Professor Agassiz. Three years later Agassiz spoke of him enthusiastically, remarking to a friend, "Clark has become the most accurate observer in the country." In June, 1860, he was appointed assistant professor of zoology in the Scientific School at Harvard University, a position he held until the expiration of his term of office.

A few weeks following his appointment he went abroad, mainly for his health, traveling in England, France, Germany and Switzerland, often on foot, and visiting the leading universities and museums. He met many scientific workers, including Allman, Alexander Braun, Gegenbaur, Haeckel, Huxley, Leuckart, von Martius, Milne-Edwards, Schleiden, but especially Owen, whose guest

he was at Sheen Lodge, Richmond Park. While in Germany he attended the meeting of German Naturalists and Physicians at Königsberg, of which he has left an interesting account in his notes of European travel.

In the spring and summer of 1861 he gave a course of lectures on histology at the Museum of Comparative Zoology. One of his friends writes:

I remember his interesting lectures before our small class on cellular structure in plants and animals. His skill with the microscope and his rare ability to draw aided him greatly in making out the minutest details of cell structure. His personal qualities were of a kind to endear him to many friends, especially to those students who sought and obtained from him counsel and advice in their studies, as I did on many occasions.

The small class included Hyatt, Morse, Packard, Putnam, Scudder, Shaler and Verrill.

Notwithstanding his constant investigations, Professor Clark found time to prepare a course of twelve lectures—the result of his microphysiological studies—which he delivered at the Lowell Institute in the winter of 1864. These were subsequently rewritten and published in 1865, under the title of "Mind in Nature; or the Origin of Life, and the Mode of Development of Animals." This work, based on structure and development in the animal kingdom, is crowded with original observations and testifies to years of the severest labor and independent thought. "It is in all respects," says Packard in 1873, "for its usually sound and clear thinking, its breadth of view and the amount of original work it contains, perhaps the most remarkable general zoological work as yet produced in this country."

Clark adopted and strongly urged the doctrine of spontaneous generation, from the facts afforded by the experiments of Jeffries Wyman, and on the question of evolution adopted views resembling those of Richard Owen. The original matter in the book is that relating to the structure of *Bacterium termo* and *Vibrio bacillus*, the theory of the egg and its polarity and bilaterality, and the

cellular structure of *Actinophrys*, with many other new points relating to the anatomy and physiology of the Protozoa and Radiates. It anticipated also certain points in histology, and the structure of the Protozoa and Sponges especially, which have made the succeeding labors of some European observers notable.

In 1866 Professor Clark accepted the chair of botany, zoology and geology at the Agricultural College of Pennsylvania, where he remained three years, exchanging it in 1869 for similar duties at the University of Kentucky. Neither of these posts was agreeable to his taste, chiefly on account of the pressure of college duties, which left him but little time for abstract investigations. It was, therefore, with great readiness he accepted the call to this college in 1872.

Here his duties were of a more congenial nature, and he applied himself with renewed energy to teaching and soon began the formation of a museum—a working collection of comparative and pathological anatomy. Turning to his first and only report—remarkable for its clearness, particularity and insight—we find that he taught human anatomy and physiology, comparative anatomy and zoology, and comparative physiology. These studies were to form the groundwork for a course in general and veterinary pathology. He lays stress on the importance of the objective method of teaching in the class-room and of laboratory instruction. "Having mastered," he says, "the general principles of structure and relation throughout the length and breadth of the animal kingdom, the rawness of total ignorance is supplanted by a new habit of thought, and a proneness to make further inquiry upon meeting with any object in nature. Here, then, comes the time for laboratory practise. Supplied with scalpel and magnifier, the student should be required to work out topics upon unprepared specimens. If he has acquired the smallest grain of interest in the matter previously, patience will enter where it could not possibly have existed before. He learns the art of seeing and knowing what he looks at; he becomes by degrees an observer; and in doing that, he is

also becoming unconsciously a draughtsman, and when required, as he should be, to produce with pencil what he sees, if he wants to do it, he will do it instinctively." Lastly, Clark had in view graduate courses for advanced work and for special training.

His work was now interrupted by a severe illness. Never robust, his assiduous and confining labors had seriously impaired his health. As early as 1857 are entries in his diary of symptoms indicating that the seeds of the disease that was to cut him off in his prime were then sown. After much suffering, on the first of July, 1873, at the age of forty-seven, his useful life came to an end. He was a member of the leading scientific societies in this country, including the National Academy of Sciences, which up to that time was limited in membership to fifty of the foremost scientists of the country.

His first love for science, writes one who knew him well, seems to have grown from his fondness for flowers. After he became a student of Professor Agassiz his love for botany remained undiminished. He studied it in after years from the side of vegetable histology and morphology in connection with and as illustrating the histology and morphology of animals. The influence of his knowledge of botany on his zoological studies was marked. It prepared him for his studies on spontaneous generation, on the theory of the cell, on the structure of the Protozoa and the nature of protoplasm. In studying the lasso-cells of the acalephs, he traced their analogical resemblance to the stinging hairs of the nettle. By his intimate knowledge of the spores of the smaller algæ he was able to point out some of the characters separating the lowest Protozoa from the spores of plants, and aid in the work of Thuret and others in eliminating from the animal kingdom certain vegetable spores which had been originally described as Infusoria.

In his first scientific paper, communicated by Dr. Gray in 1856, he showed that in most of our North American gentians the ovules are spread over the whole parietes of the ovary, either irregularly or in vertical lines on the

veins. His next paper was on the peculiar growth of rings in the trunk of *Rhus toxicodendron*, and this was supplemented by further studies on the eccentricity of the pith of *Ampelopsis quinquefolia* and *Celastrus scandens*. He made experiments for a series of years on the value of the bark to the life of the tree. He observed the relation and development of the filaments which connect the anthers to the sepals of *Comandra umbellata*. In his paper on the identity of the vibrios and the muscular fibrillæ, he showed how the latter during decomposition break up transversely, the fragments assuming the form and movements of the former. He also made observations on the absorption of albumen in the cells of plants. His last purely botanical paper (1859) was on the nature of the glandular dots of the pine. His skill in the use of the fine lenses made by Spencer (under his direction) enabled him to see more than his predecessors of the true relations of these dots. But his botanical studies did not end here, as may be seen by reference to his diaries and his frequent allusions to the lower algæ and to vegetable histology in "Mind in Nature." In his walks he often botanized, and contributed in this way to Gray's botanical textbooks. Thus with the training he received from Gray and Agassiz, he looked upon the world of organized beings from both the botanical and zoological side. He well deserves the name, *biologist*.

Between 1856 and 1863 he was associated with Agassiz in the preparation of the anatomical and embryological portions of the great work entitled "Contributions to the Natural History of the United States." To these volumes he was a large contributor, most of the histological and embryological portions of the work being his, and more than half the plates illustrating the embryology and histology of the turtles and acalephs bear his name. "In the preparation of this part of my work," says Professor Agassiz, "I have received much valuable assistance from my friend and colleague Professor H. J. Clark, who has traced with me, for more than nine years, the metamorphoses of our Aculephs,

and especially those of the Hydroids. He discovered the peculiar structure of the lasso-cells of the *Otenophora*."

During this time Clark began the serious study of the Protozoa, undoubtedly compelled to do so in order to properly interpret the histological facts then accumulating in the study of the Radiates. After leaving Cambridge he studied the Infusoria and lower plants, and made drawings and notes comprising descriptions of many new forms of Infusoria. He planned an extensive work upon this subject, which, had he lived to complete it, might have equalled if not surpassed Claparède and Lachmann's famous work on the Infusoria. He did not dissociate the Protophyta from the Protozoa, regarding them as almost inseparable in nature; thus, in his lectures to his classes, well nigh anticipating Haeckel's classification of the lowest forms of the animal and vegetable kingdom into the Protista and Protozoa.

In his first paper on *Actinophrys* (1863) he announced the discovery that "all vibratile cilia originate in the amorphous intercellular substance," and do not form direct prolongations of cells, *i. e.*, that cilia are prolongations or extensions of the protoplasmic substance of the cells from which they arise. The same year he discovered the eggs of *Tubularia*, and showed that there was but one type of development in the Hydromedusæ (excepting the Narcomedusæ and Trachymedusæ), and that the differences observed in the developmental process were merely modifications of degree and not of kind, an exceedingly valuable addition to our knowledge of the affinities of the various groups of Hydromedusæ.

Foremost, perhaps, among his several discoveries with the microscope was that of the true nature of the cilio-flagellate infusorians and the sponges. In 1866 appeared a brief paper, entitled "Conclusive Proofs of the Animality of the Ciliate Sponges, and of their Affinities with the Infusoria Flagellata." While Clark had endeavored to show in his Lowell Lectures that there was a unity of plan in the organization of the Protozoa, their

bodies being arranged in the form of a helix, he now endeavored to prove that the sponge did not depart from the protozoan type. In the full memoir, published about a year later, under the title "*Spongiæ Ciliatæ as Infusoria Flagellata*," he attempted to establish the homology of the flagellate cells of the sponge with the flagellate Infusoria. His discovery of the flagellated cells of living sponges and demonstration of their animal nature was a great step in advance of previous observers. While, as Clark observes, Carter had first detected the true criterion of their animality, this was confirmed and demonstrated still more completely by Clark himself, as acknowledged by Carter in his "Confirmation of Professor James-Clark's Discovery of the True Form of the Sponge-cell (Animal)."

The Choanoflagellata, or collar-bearing flagellate animalcules, were discovered by Clark, and his further discovery that the flagellated (ciliated) chambers of sponges are lined by collared cells of the same peculiar structure as the individual Choanoflagellata, led him to regard the sponges as colonies of Choanoflagellata. The views maintained by Clark with reference to the position and affinities of the sponges were, that these organisms must be regarded as compound colonial forms of Flagellata, whose units, in the case of *Leucosolenia*, exhibited a type of structure essentially similar to that of *Codosiga* and *Salpingoeca*—genera established by him to receive his collared cell forms—but might possibly in other instances more closely approximate to that of *Monas* (*Spumella*) *Bicosaca* or *Anthophysa*. In these views he was supported by the observations of Saville Kent and Stein, and in the main by those of Carter and to a less extent by Balfour, but opposed by Haeckel and F. E. Schulze. The subsequent discovery by Saville Kent of *Proterospongia* (*Savillia*) at that time rendered the derivation of the sponges from the Flagellata at least a tenable hypothesis, while Balfour considered them as an intermediate group between the Protozoa and Metazoa.

In the last paper he published Clark compared the arguments adduced by Haeckel in

favor of the coelenterate affinities of the sponges with the actual structural composition of *Spongilla* and *Leucosolenia*, and reached the conclusion that the relationship of the sponges to certain flagellate Protozoa was so distinct and decisive as to forbid their logical inclusion among the representatives of any other class. The universal and characteristic collared cells of sponges point emphatically to a choanoflagellate ancestry and, as a recent authority has observed, in the present state of our knowledge it would be difficult to frame a definition of the Protozoa which should absolutely exclude the sponges. His work on flagellate Protozoa and sponges was a valuable contribution to science. Since his time great advance has been made in our knowledge of the histological structure, mode of reproduction and embryological development of these organisms, due mainly to the opportunities offered by novel and refined methods of technique. Had the art of making thin sections and the staining of tissues been known in his day, he would certainly have anticipated much of the later work of cytologists and embryologists.

In the use of the microscope, Clark showed not only mechanical skill and ingenuity, but a patience, caution, and experience in difficult points in histology, which undoubtedly placed him at the head of observers in this country and rendered him perhaps inferior to few in Europe. He used the highest powers with a skill that few if any living observers have surpassed. He suggested improvements carried out by Spencer and Tolles in this instrument. In 1857 Professor Agassiz sent him to Canastota to confer with Spencer, and as a result a microscope was made by him which was fully equal to any made at that time in Europe. Clark suggested that we must have three kinds of objectives: one with the field extremely flat; another, an immersion lens—the first made, so far as we are aware, and now so universally used; and a “third with a deepthing focus extending as far as possible beyond that of the ordinary kind, for the purpose of viewing objects as a whole, in order to

ascertain the relations of their different parts.” This microscope was in use in 1859.

In 1878, five years after the death of Professor Clark, the Smithsonian Institution published, as one of its Contributions to Knowledge, his monograph of the “Lucernariæ and their Allies.” This group was the subject of his last studies, though one which had early engaged his attention. Complete and elaborate as it is so far as it extends, this beautiful memoir is only a fragment of what was evidently designed to cover at least fifteen parts, two parts only having an actual existence. It has been well said that a broken shaft would represent both the author's life and this posthumous work, each symmetrical and thoroughly finished to the point where they suddenly broke off.

The Lucernarians were not regarded by Clark as truly radiate animals, but in a degree bilateral, with a fore and hinder end. The commonly received theory at that time that the so-called Radiata are founded upon the idea of radiation, was combated by him in 1865. The views of the present day coincide in the main with his—that radiation is, on the whole, a superficial feature, not always constant in Cuvier's Radiata, though often well marked. He regarded the so-called polymorphic individuals as “organs under various disguises,” and he ascribed a high degree of individuality to the jelly-fish, *Pelagia*, and only a less amount to *Lucernaria*. He believed with the advanced histologists of his day that “cells so-called (no matter whether constituted according to the older histologists or according to the most recent theory) are, after all, of secondary importance, and that the *cytoblastema* or protoplasm (which we do not distinguish from intercellular substance) is in the main an *essential element*, the potential progenitor of all tissues, and that it projects itself into the utmost feature of the living body by a process of self-proliferation. Through this, and this only, can a true *law of continuous development* be illustrated; while the various forms of cell-tissue, and fiber-tissue, and bone-tissue, etc., are but the disjointed collateral developments,

each one irrespective of the other, from the continuous, onward stream of cytotblastema." He says, further, that "all Rhizopods are moving, sentient masses of *Cytoblastema*, and that alone."

Clark was admirably adapted by nature for doing histological work of the highest order. He possessed that philosophic insight of the true naturalist which often enables him to *divine* much further than he can perceive in the tracing of relationships and to anticipate what the microscope is to reveal. At the time he began his work as an observer, zoological science in America was especially deficient in histological investigations, and he did more than any one else to remove this reproach upon American biology.

"Henry James Clark," said Asa Gray at the time of his death, "deserves to be enrolled in the list of botanists. Although his high reputation was won in another department, he was an excellent botanist before he became Mr. Agassiz's assistant and gave himself to zoological investigation: the present writer was indebted to him for more than one interesting discovery of points of structure. He is thought to have been the ablest microscopic investigator which this country has produced." "His labors as a zoologist," said James D. Dana, "especially in those departments requiring difficult microscopic research, had placed him among the two or three first in the country, and given him a world-wide reputation. He was always working, and full of enthusiasm in science, and also a most genial and excellent man."

In the preface to volume one of the "Contributions to the Natural History of the United States," dated October 3, 1857, Professor Agassiz says:

Mr. H. James Clark has assisted me from the beginning of my investigation of the embryology of these animals, and drawn, with untiring patience and unsurpassed accuracy, most of the microscopic illustrations which adorn my work. I owe it to Mr. Clark to say, that he has identified himself so thoroughly with my studies since he took his degree in the Lawrence Scientific School, that it would be difficult for me to say when I

ceased to guide him in his work. But this I know very well, that he is now a most trustworthy observer, fully capable of tracing for himself the minutest microscopic investigation, and the accuracy of his illustrations challenges comparison.

In a lecture given at the summer school of Natural History at the Island of Penikese, early in July, 1873, Professor Agassiz announced the death of Professor Clark and spoke in the highest terms of his work and of him as a man. He said that as a microscopist and histologist he regarded him as fully equal if not superior to Ehrenborg, who was at that time considered the best in the world.

Professor Fernald, to whom we owe the department of entomology in this college and in whose honor we are gathered to-day, has expressed the opinion that he was the most brilliant of all the young men that Agassiz drew round him when he first came to this country; that as an artist in illustrating his work he probably had few if any equals, and as an observer and investigator he must be placed in the front rank of the naturalists of his time. In marine zoology he probably had no superior, and if his life had been spared he would undoubtedly have left a marked impress on the college.

Three things can be said of Clark. He was a genius, he had the best of teachers, and he made the most of his opportunities. The secret of his success as an investigator may be stated in his own words taken from his diary, where he says, "I made it a rule to practise the utmost rigidity and thoroughness in my researches, without regard to time consumed or the value of the results." Such was the life of Henry James Clark, full of supreme devotion to science and showing an indomitable energy in the search for truth.²

FREDERICK TUCKERMAN

²Several species bear his name. Agassiz dedicated to him the aculeph, *Idyiopsis clarkii*; Bütschli the animalcule, *Salpingæca clarkii*—a name later bestowed by Stein upon another form of the same genus. His services² are also commemorated in *Ascoris clarkii* of Verrill, the most delicate species of calcareous sponge found on our coast.

SCIENTIFIC NOTES AND NEWS

COMMEMORATION day will be observed by the University of Glasgow on June 25, when Professor F. O. Bower, F.R.S., will deliver an oration on "Sir Joseph Hooker."

THE Aero Club of Washington held a field day last Monday in commemoration of the anniversary of Secretary Langley's first aerodrome flight on May 6, 1896. Professor Willis L. Moore, president of the club, gave an address on Langley's work and influence on aviation. General Robert Shaw Oliver spoke on the work of the army in aviation, and Captain W. I. Chambers, on the work of the navy.

A PORTRAIT of Dr. Edgar F. Smith, provost of the University of Pennsylvania, painted by Mr. Hugh H. Breckenridge, will be presented to the university by the members of the class of 1902 College on the occasion of their tenth anniversary this June.

THE speaker at the annual commencement exercises of the Johns Hopkins University on June 11 will be Dr. William C. Gorgas, chief sanitary officer of the Panama Canal Zone and member of the Isthmian Canal Commission.

DR. WILHELM FIEDLER, professor of mathematics at Zurich, has celebrated his eightieth birthday.

MAJOR VON ABERCRON, known for his work in aeronautics, has been made an honorary doctor by the University of Marburg.

DR. ADOLF VON KOENEN, professor of geology at Göttingen, has received the honorary doctorate of engineering from the Technological Institute of Hanover.

AT the celebration of the seventy-fifth anniversary of the foundation of the University of Athens, on April 10, honorary degrees in medicine were conferred, as reported in *Nature*, on Professors von Behring (Marburg), Celli (Rome), Ehrlich (Frankfort), Exner (Vienna), Golgi (Pavia), Kronecker (Berne), Laudouzy (Paris), Richet (Paris), Sir Ronald Ross (Liverpool), Roux (Paris), Schulze (Würzburg), Weichselbaum (Vienna) and others. The degree of doctor of philosophy was conferred on Sir Donald MacAlister

(Glasgow), Delbrück (Jena), Dürpfeld (Athens), Gubernatis (Rome), Harnack (Berlin), Kenyon (London), Mahaffy (Dublin), Wheeler (Berkeley) and others; and the degree of doctor of science on Professor Depéret (Lyons), Halácsy (Vienna), Lacroix (Paris), Lepsius (Darmstadt), Partsch (Leipzig) and Philippson (Bonn).

THE third annual award of the Hunterian Society's medal has been made to Dr. A. Goulston, of Heavitree, Exeter, for his essay on "The Use of Sugar in Heart Disorders."

GRANTS have been made from the C. M. Warren Fund of the American Academy of Arts and Sciences as follows: To Professor H. G. Byers, University of Washington, \$250, for work upon the passivity of metals. To Professor W. D. Harkins, University of Montana (to be at Chicago University), \$300, for work upon the energy relations in a surface between two liquid phases. To Dr. Latham Clark, Harvard University, \$150, for work on the paraffin hydrocarbons.

MR. R. N. LYNE, director of agriculture in Portuguese East Africa, has been appointed the director of the new agricultural department of Ceylon.

DELEGATES have been appointed by the Academy of Natural Sciences of Philadelphia as follows: To the Second International Congress of Entomology, Dr. Henry Skinner, Professor Philip P. Calvert and Dr. W. J. Holland; to the Eighteenth International Congress of Americanists, Sir Thomas Lauder Brunton.

DR. EDWARD BARTOW, director of the State Water Survey and professor of chemistry at the University of Illinois, has been appointed a delegate to the fifteenth International Congress of Hygiene and Demography, to be held in Washington, September 23 to 28.

DR. H. B. WARD, head of the zoological department of the University of Illinois, has been appointed delegate of the Illinois Academy of Science to the meetings of the Iowa Academy of Science at Des Moines. He will deliver two addresses.

THE New York Section of the American Chemical Society has appointed a committee on occupational diseases in chemical trades as follows: Charles Baskerville, professor of chemistry, College City New York, *Chairman*; E. C. Uhlig, chief chemist, Brooklyn Union Gas Co., Brooklyn, *Secretary*; George P. Adamson, Baker and Adamson Chemical Co., Easton, Pa.; W. H. Bassett, American Brass Co., Waterbury, Conn.; Wm. F. Doerflinger, consulting chemist, 52 Beaver St., New York City; H. M. Kaufman, Mutual Chemical Company of America, 55 John St., N. Y.; A. C. Langmuir, chairman of the New York Section, American Chemical Society, 9 Van Brunt St., Brooklyn, N. Y.; Geo. A. Prochazka, general manager Central Dye Stuff and Chemical Company; Geo. D. Rosengarten, Powers, Weightman and Rosengarten, Philadelphia, Pa.; A. H. Sabin, consulting chemist for the National Lead Company, 129 York St., Brooklyn, N. Y.; Charles L. Parsons, mineral chemist, Bureau of Mines, Washington, D. C. This committee will work in cooperation with the committee of the Association for Labor Legislation.

DEAN EUGENE DAVENPORT, of the College of Agriculture of the University of Illinois, was the speaker at the recent commencement exercises of the University of Nebraska College of Agriculture.

R. G. DUKES, professor of applied mechanics at Purdue University and second of the exchange lecturers with the University of Illinois, lectured April 26 on "The Recent Discoveries in Physical Science and their Bearing on the Progress of Engineering." Mr. O. P. Hood, who is mechanical expert for the United States Bureau of Mines at Pittsburgh, also addressed the meeting.

DEAN C. H. JOHNSTON, of the University of Kansas, gave three lectures before the School of Education of the University of Illinois on April 29 and 30 on present problems in high school organization.

THE annual commencement address of the Missouri School of Mines will be given by

Mr. James R. Finlay, of New York City. Exercises will be held on the morning of May 31. The graduating class numbers forty.

THE University of Pennsylvania Chapter of the Society of the Sigma Xi initiated twenty-nine new members on April 23. Among them were Professor Samuel Christian Schmucker, of the West Chester State Normal School, and Mr. Witmer Stone, a curator in the Academy of Natural Science in Philadelphia. Professor George Hervey Hallett, of the University of Pennsylvania, addressed the Chapter on the subject of "Hyperspace." Professor George F. Sever, president of Columbia chapter, was present as a delegate from that chapter.

THE Museum of the University of Pennsylvania has arranged to send an expedition to the Amazon under the direction of Mr. Algot Lange. The expedition will be furnished with a steamer which will be large and seaworthy enough to carry the party from New York to the mouth of the Amazon and up the Amazon for several thousand miles to the tributaries where the Indian tribes will be studied and collections made for the next three years.

MR. GEORGE BORUP, a graduate student in geology at Yale University, and Mr. S. W. Case, a graduate student in mining, were drowned in Long Island Sound on April 28, by the overturning of a power canoe. Mr. Borup accompanied Commander Peary in his Arctic expedition, and had planned to undertake this summer with Mr. D. B. McMillan, an expedition to Crocker Land, as described in a recent issue of SCIENCE.

THE heirs of the late Frau Adelheid Bleichröder have given the German Association of Physicians and Scientific Men \$25,000 for the support of research work in medicine and the sciences contributory to medicine.

THE provisional arrangements for the forthcoming celebration of the 250th anniversary of the Royal Society, as given in *Nature*, are as follows: Monday, July 15—An evening reception of delegates at the rooms of the Royal Society. Tuesday, July 16—In the

morning a commemorative service in Westminster Abbey; in the afternoon the official reception of delegates at the Royal Society and presentation of addresses; in the evening a commemorative dinner at the Guildhall. Wednesday, July 17—In the morning visits to places of interest in London; in the afternoon the Duke of Northumberland gives a garden-party at Sion House; in the evening a conversazione in the rooms of the Royal Society. Thursday, July 18—In the morning visits to places of interest in London; in the afternoon H.M. the King gives a garden-party at Windsor, to which the delegates and fellows of the society will be invited. Friday, July 19—The delegates will visit Oxford and Cambridge Universities.

THE coming of age of the Babcock butter-fat test, which was invented by Professor S. M. Babcock, of the University of Wisconsin, twenty-one years ago, has been recognized by the university in a new bulletin written by Dean H. L. Russell, of the College of Agriculture, in which he gives the history and growth of the use of the test throughout the world. Pictures of the original testing machine, now in the dairy school of the university, and of the latest improved forms of testers are shown in the bulletin.

THE prize of the foundation George Montefiore will be awarded 1914 for the scientific advancement or application of electricity. The works may be printed or in manuscript and must be in French or English. The value of the prize is \$4,000 and the works must be received not later than March 31, 1914.

THE Warren Triennial Prize, founded by the late Dr. J. Mason Warren, of Boston, in memory of his father, will be awarded in 1913 for the best dissertation on some subject in physiology, surgery or pathological anatomy, the arbitrators being the physicians and surgeons of the Massachusetts General Hospital. The amount of the prize is \$500.

THE surgeon general of the army announces that preliminary examination for the appointment of first lieutenants in the army medical corps will be held on July 15, 1912, and Sep-

tember 3, 1912, at points to be hereafter designated. Full information concerning these examinations can be procured upon application to the "Surgeon General, U. S. Army, Washington, D. C." The essential requirements to securing an invitation are that the applicant shall be a citizen of the United States, shall be between twenty-two and thirty years of age, a graduate of a medical school legally authorized to confer the degree of doctor of medicine, shall be of good moral character and habits, and shall have had at least one year's hospital training, after graduation. The examinations will be held concurrently throughout the country at points where boards can be convened. Due consideration will be given to localities from which applications are received, in order to lessen the traveling expenses of applicants as much as possible. The examination in subjects of general education (mathematics, geography, history, general literature and Latin) may be omitted in the case of applicants holding diplomas from reputable literary or scientific colleges, normal schools or high schools, or graduates of medical schools which require an entrance examination satisfactory to the faculty of the Army Medical School. In order to perfect all necessary arrangements for the examination, applications must be complete and in possession of the adjutant general at least three weeks before the date of examination. Early attention is therefore enjoined upon all intending applicants. There are at present sixty-eight vacancies in the medical corps of the army.

THE trustees of Phillips Academy, Andover, Mass., have authorized the department of archeology to begin an archeological survey of Maine this year. Already the curator, Mr. W. K. Moorehead, has had an agent of the department in Maine for some weeks. A number of camp sites, cemeteries and other places have been entered on the standard government maps. It is proposed to map the entire state. The indications are that the ancient Indian population was most numerous along the coast, about Sebago Lake, on the lower Penobscot, Moosehead Lake and Cham-

berlain Lake. A number of students will accompany Mr. Moorehead and others to Maine in June. The excavation of one or two sites will be begun in May.

THE University of Michigan Museum of Natural History will send an expedition to Nevada in July and August to secure zoological material for research and illustrative purposes. The investigations will be carried on as the museum conducts all of its field work outside of the state, that is, only a few groups and a small area will be considered and these will receive detailed study. One half of the expense of the expedition will be provided by Mr. Bryant Walker and one half by the university. The museum will also this summer begin a biological survey in the northern part of Chippewa County, Michigan. Hon. George Shiras 3d has provided for the expenses that will be incurred in the preliminary work this summer, and the Michigan Geological and Biological Survey and the museum will complete the study.

THE program of business for the eighteenth annual meeting of the British Medical Association in Liverpool has been issued. The representative meeting will begin on July 19. The annual general meeting will take place on the afternoon of July 23, and the president, Sir James Barr, will deliver his address in the evening. The sectional meetings will be held on July 24, 25 and 26. The address in medicine will be delivered by Dr. G. A. Gibson, of Edinburgh, and the address in surgery by Mr. F. T. Paul, of Liverpool. The scientific program of the meeting will be conducted in 20 sections.

THE Anglo-American Medical Association, which was founded in Berlin some eight or nine years ago and reconstituted in 1910, has recently acquired, as we learn from the *British Medical Journal*, well-situated quarters of its own at the Hotel Atlas, 105, Friedrichstrasse. They are open daily from 12 to 2 for luncheon; the assistant secretary is in attendance from 1:30 to 4:30 to give information; and from 9 P.M. to 12 P.M. the rooms are open for social purposes, writing and perusal of the journals

with which the association keeps itself supplied. In addition, there is a formal meeting each Saturday at 8 P.M., when dinner is taken and a paper read and discussed. One of the special objects of the association is to make the visits of British and American medical men to Berlin pleasant and informing by putting them promptly in touch with what is going on in medical and surgical circles, and by enabling them to meet on a social footing their colleagues in Berlin. It publishes a year-book, the current issue of which contains, in addition to other notes, information as to courses on various subjects more or less constantly in progress, and also as to vacation and other special courses. The honorary secretary and treasurer of the association is Mr. H. R. Carstens.

THE Smithsonian Institution reports the completion of the fish collecting in the Panama Canal Zone, and the safe return of one of its representatives. Several of the specialists who have been making collections in this region have been back some time, but the members of the party who have been collecting fishes did not complete the work until early in April, remaining three months in the field. This branch of the work has been supported by the cooperation of the U. S. Bureau of Fisheries and the Field Museum of Natural History, Chicago, Mr. S. F. Hildebrand representing the former and Dr. S. E. Meek the latter. After the work was finished, and the collections shipped to Washington, Dr. Meek went on a visit to Costa Rica, while Mr. Hildebrand returned to Washington, where he arrived on April 13. Mr. Hildebrand reports a most successful trip, and feels confident that all the important fishes of the Canal Zone are represented in the collections which fill some 5 or 6 barrels. The weather was favorable and the work was greatly facilitated by the many privileges and courtesies extended by the Canal Commission. Quarters were furnished by the commission, and each member of the survey was supplied with the regular hotel and commissary books, according him the privileges of an employee.

Living under these arrangements, the party was enabled to secure excellent meals at a very low cost. Besides the work in the Canal Zone proper, the members of the survey made trips into the neighboring territory in search of specimens and data not available within the actual bounds of the zone, but obtainable in the same faunal area or an adjoining one. One of these expeditions carried the party into the Darien country and along the banks of the Rio Tuyra, which lies on the Pacific side of the isthmus about 150 miles distant from Panama. The fauna of this country was found to differ considerably from that of the Canal Zone. The fish collectors, unlike those concerned with some other classes of animals, find it impracticable to classify their specimens while in the field, and for this reason it is difficult to say just what has been obtained, other than that a good-sized collection was made, fully as large as that of last year. The fish were caught in nets and traps of several kinds; often in great numbers, the collectors selecting the best and most desired specimens which are at once prepared and packed in tanks for shipment to the National Museum. Among the different kinds of salt-water fishes secured were sharks, tarpon, jew-fish, snappers, groupers and croakers. There were also many of the cat-fishes which are so very abundant on the Pacific slope and along the coast of Panama. The collectors point out the special value of this survey in so far as concerns the fish fauna which will become completely changed and intermixed when the canal is finished, and the waters of the inland lakes and the two oceans become intermingled. As is well known, many salt-water fishes ascend fresh-water streams for long distances, and it is now seen that in this manner many will doubtless find their way to the great Gatun Lake. Some will probably remain here, while others will pass on into the ocean. At present the fish faunas of the Atlantic and Pacific slopes and the two coasts of the zone appear well defined, but it is believed that a subsequent survey, in from five to ten years time, will reveal great changes.

UNIVERSITY AND EDUCATIONAL NEWS

THE late Dr. Francis Bacon, a physician of New Haven and connected with the Yale Medical School, has bequeathed \$100,000 to the New Haven County Antituberculosis Society. He has made Yale University his residuary legatee, the bequest to be used as a scholarship fund in the college.

MR. A. W. OPPENHYM, of New York, by his will created a trust fund of \$275,000, which at his widow's death shall go in equal parts to the Mt. Sinai Hospital, the German Hospital and Columbia University. It is provided that the Columbia University fund is to be used for the research into the cause, prevention and cure of cancer.

MR. JOHN TATLOCK, of New York, has given to Columbia University a collection of astronomical works consisting of 261 volumes and about 1,200 pamphlets.

AGRICULTURAL HALL, just built by the University of California at a cost of \$200,000 to house some portion of its teaching and investigating in agriculture, will be completed by commencement, May 15, 1912. This new white granite building, roofed in red mission tile, and picturesquely set on an eminence looking south toward the Dana Street entrance to the campus, is one of the permanent buildings of the Phoebe A. Hearst plan. It is fireproof in construction, with steel frame and concrete floors and roof.

THE bill appropriating two hundred and fifty thousand dollars for the development of work in public health and medicine at the site of the University of Illinois in Urbana-Champaign, failed of passage in the special session of the legislature. Although only four votes were recorded against it; yet owing to the fact that at a special session a two-thirds majority is necessary to pass an appropriation bill, involving in this case thirty-four votes, and at no time were more than thirty-five members present, it made it possible for even two votes to defeat the bill. The trustees will renew their request for an adequate appropriation for scientific work in medicine at the next session of the legislature.

PROFESSOR GORDON H. TRUE has been appointed director of the Nevada Experiment Station, at Reno.

DR. ARTHUR B. LAMB, professor of chemistry and director of the Havemeyer Chemical Laboratory of New York University, has been appointed assistant professor of chemistry at Harvard University. Professor Solon I. Bailey has been promoted to the Philips chair of astronomy vacant by the retirement of Professor Arthur Searle, and Dr. Charles Palache has been promoted to a full professorship of mineralogy.

DR. IRA W. HOWERTH, of the University of Chicago, has been appointed professor of education and director of university extension in the University of California. Dr. J. C. Merriam has been promoted to a full professorship of paleontology.

DR. W. M. CONGER MORGAN, assistant professor of chemistry at the University of California, has been appointed professor of chemistry in Reed College.

DR. FRANZ DOFLEIN, associate professor of zoology at Munich, has been called to the chair of zoology at Freiburg.

DISCUSSION AND CORRESPONDENCE

NON-EUCLIDEAN GEOMETRY IN THE ENCYCLOPEDIA BRITANNICA

THE sixth heading under the word Geometry is Non-Euclidean Geometry. The article is by Whitehead and Bertrand Russell, the best men in England to have written it, and is worthy this one of the three greatest works of reference in the English tongue, the others being Murray's dictionary and the Century.

It begins:

A short historical sketch will . . . describe the famous and interesting progress of thought on the subject.

But first it gives characteristic properties, beginning with Bolyai's space.

The sum of the three angles of a triangle is always less than two right angles. The area of the triangle ABC is $\lambda^2(\pi - A - B - C)$. If the base BC of a triangle is kept fixed and the vertex A

moves in the fixed plane ABC , so that the area ABC is constant, then the locus of A is a line of equal distance from BC . This locus is not a straight line.

I have called it an *equidistantial*.

The angle A [which a perpendicular to one of two parallels makes with the other] is called by N. I. Lobatchewsky the "angle of parallelism."

Here as everywhere else in the spelling of Lobachevski's name, the authors have made a very regrettable slip. Lobachevski transliterated his own name into French as Lobatcheffsky, and so it stands in the "édition de Kasan," 1886.

In 1869 Potocki transliterates the name into French as Lobatchefsky, and this spelling is used in the French prospectus issued at Kazan to found the great Lobachevski prize; and the volume "In Memoriam N. I. Lobatschevskii," bears as subtitle, Collection des mémoires présentées à la Société Physico-mathématique de Kasan pour la fête de l'inauguration du monument de Lobatchefsky (1/13 Septembre, 1896) par Mm. Hermite, Halsted, Girardville, Laisant, Lemoine, Neuberg, Ocagne.

My contribution I wrote while sojourning in Kazan, where I had abundant opportunities to learn the name. Gino Loria adopts in Italian the spelling Lobatschefsky. Now Lobachevski himself also transliterated his name into German, and it stands on the title page of the original edition of his Geometrische Untersuchungen as Lobatschewsky. But Stäckel and Engel Germanize it as Lobatschefskij, the abomination *ij* being an attempt to represent the *i*, as in Italian, and the *i*, very short, with which the name ends in Russian. My friend Sommerville falls into this pit, and spells the name Lobačevskij. Had he dropped that *j* and replaced his fifth letter by its exact equivalent, our *ch* as in church, he would have had the proper English transliteration, Lobačevski.

If we be willing to permit in the Encyclopædia the final *y*, still as English its *t* is superfluous and its *w* is indefensible, so that, as the name occurs 25 times, there are 50 places where the quicker the stereotype plates

are corrected the better. Let not the name of a world hero be bungled in the world language, English.

The theory of parallels as it exists in hyperbolic space has no application in elliptic geometry. But another property of Euclidean parallel lines holds in elliptic geometry, and by the use of it parallel lines are defined. Thus throughout every point of space two lines can be drawn which are lines of equal distance from a given line l .

This property was discovered by W. K. Clifford. The two lines are called Clifford's right and left parallels to l through the point.

In both elliptic and hyperbolic geometry the spherical geometry is the same as the "spherical trigonometry" in Euclidean geometry.¹

The historical sketch is blemished by the unwarranted prominence it gives to Gauss. It says:

We find him in 1804 still hoping to prove the postulate of parallels. In 1830 he announces his conviction that geometry is not an a priori science; in the following year he explains that non-Euclidean geometry is free from contradictions, and that, in this system, the angles of a triangle diminish without limit when all the sides are increased. He also gives for the circumference of a circle of radius r the formula $\pi k(er/k - e^{-r/k})$.

[In this formula the Encyclopædia has a misprint.]

But all that and immensely more had been given by John Bolyai in 1823 and by Lobachevski in 1826, and published in 1829, while as our authors themselves say, "Gauss published nothing on the theory of parallels."

Then comes the most offensive clause:

It is not known with certainty whether he influenced Lobachevski and Bolyai, but the evidence we possess is against such a view.

But it *is* known that he did *not*, and the evidence we possess against any such influencing is absolute and final. The very next sentence is the opening one of my Translator's Preface, 1891:

Lobachevski was the first man ever to publish a non-Euclidean geometry.

Of Bolyai's work is said:

¹ See chapter XVI., Pure Spherics, in my "Rational Geometry."

Its conception dates from 1823. It reveals a profounder appreciation of the importance of the new ideas, but otherwise differs little from Lobachevski's. Both men point out that Euclidean geometry is a limiting case of their own more general system.

[The Encyclopædia, by a misprint, has *as* for *is*.]

The works of Lobachevski and Bolyai, though known and valued by Gauss, remained obscure and ineffective until, in 1866, they were translated into French by J. Houël.

Bolyai was not translated until 1868. Not only were these known to Gauss, but I called attention to the very significant fact that the striking work of Saccheri, truly a non-euclidean geometry, was in the Göttingen library and freely accessible to Gauss during the years 1790-1800. See Gino Loria,² who says of Gauss:

Ignoto fino a qual punto egli siasi spinto nella nuova via, come è ignoto se egli abbia ricevuto qualche ispirazione dall' opera del Saccheri che esisteva a Gottinga negli anni 1790-1800 (essendo segnata con un asterisco nella *Bibliotheca mathematica* del Murhard).³

If figures are to be freely movable, it is necessary and sufficient that the measure of curvature should be the same for all points and all directions at each point. Where this is the case, it *is* the measure of curvature. . . .

This *it* should be *if*.

If *a* be positive, space is finite, though still unbounded, and every straight line is closed—a possibility first recognized by Riemann.

This, as it stands, is a mistake. On page 24 of von Staudt's "Geometrie der Lage" (1847) we read:

Eine Gerade erscheint hiernach . . . als eine geschlossene Linie.

The possibility first recognized by Riemann is that straight lines may be finite.

On page 729 occurs the long dead phrase "anharmonic ratio," now happily superseded everywhere by Clifford's "cross ratio."

² Il passato ed il presente delle principali teorie geometriche. Terza edizione, 1907, pp. 286-287.

³ Osservazione fatta dall' Halsted nell' articolo "The Non-Euclidean Geometry Inevitable" inserito in *The Monist*, July, 1894.

It is explained in section VII. in what sense the metrical geometry of the material world can be considered to be determinate and not a matter of arbitrary choice. The scientific question as to the best available evidence concerning the nature of this geometry is one beset with difficulties of a peculiar kind. We are obstructed by the fact that all existing physical science assumes the Euclidean hypothesis. This hypothesis has been involved in all actual measurements of large distances, and in all the laws of astronomy and physics. The principle of simplicity would therefore lead us in general, where an observation conflicted with one or more of those laws, to ascribe this anomaly, not to the falsity of Euclidean geometry, but to the falsity of the laws in question. This applies especially to astronomy. . . . But astronomical distances and triangles can only be measured by means of the received laws of astronomy and optics, all of which have been established by assuming the truth of the Euclidean hypothesis. It therefore remains possible that a large but finite space constant, with different laws of astronomy and optics, would have equally explained the phenomena. We can not, therefore, accept the measurements of stellar parallaxes, etc., as conclusive evidence that the space constant is large as compared with stellar distances.

Finally, it is of interest to note that, though it is theoretically possible to prove, by scientific methods, that our geometry is non-Euclidean, it is wholly impossible to prove by such methods that it is accurately Euclidean. For the unavoidable errors of observation must always leave a slight margin in our measurements. A triangle might be found whose angles were certainly greater, or certainly less, than two right angles; but to prove them *exactly* equal to two right angles must always be beyond our powers.

This I have been publishing for the past 35 years in articles some 77 of which, not counting translations, Sommerville has registered in his Bibliography of non-euclidean geometry, 1911. But just here a former pupil of mine, Dr. R. L. Moore, has gone beyond his teacher. His results seem to be unknown to the Encyclopædia, though I called attention to them in SCIENCE, October 25, 1907, under the "scare" heading, "Even Perfect Measuring Impotent."

In the brief bibliography appended to this

section VI., I notice a number of errors. In the title of Engel's book the *y* should be *ij*. In the title of Dehn's article, the word *Legendarischen* should be *Legendre'schen*. In the title of Barbarin's book the capital G and capital E should be lower case letters, and the hyphen should be omitted.

In the title of Bonola's book the capital E should be lower case.

In the title of the article by E. Study the *nicht-Euklidische* should be *Nicht-Euklidische*. This title upon a pamphlet of 97 pages [Greifswald, 1900] is *Über Nicht-Euklidische und Linien-Geometrie*.

In the title of Beltrami's article given on page 728, note 3, the *g* should be a capital in *Geometria* and the *E* lower case in *non-euclidea*. In note 4, page 725, *nicht-Euklidischen* should be *nichteuclidischen*. In note 1, page 727, *nicht-Euklidische* should be *nicht-euklidische*.

The final heading, VII., is *Axioms of Geometry*, under which it is said:

The second controversy is that between the view that the axioms applicable to space are known only from experience, and the view that in some sense these axioms are given *a priori*.

Both these alternatives are wrong. These axioms are assumptions, belonging to what I have treated under the title "The Unverifiable Hypotheses of Science," in *The Monist*, October, 1910.

The cruder forms of the *a priori* view have been made quite untenable by the modern mathematical discoveries. Geometers now profess ignorance in many respects of the exact axioms which apply to existent space, and it seems unlikely that a profound study of the question should thus obliterate *a priori* intuitions. . . . The enumeration of the axioms is simply the enumeration of the hypotheses of which some at least occur in each of the subsequent propositions.

On page 732, line 14, the comma after the word "however" is a misprint, and should be deleted.

Geometry with the assumption: Of any three points of a straight there is always one and only one which lies between the other two, Whitehead calls "descriptive geometry," a

horrible piece of nomenclature, which no one should adopt, since this name belongs to the system of Monge, 1794, for representing solids in a plane, though also used by Sylvester for a geometry excluding all notions of quantity, such as my "Synthetic Projective Geometry."

The article proceeds to the simplest statement of all. Descriptive Geometry is then conceived as the investigation of an undefined fundamental relation between three terms (points); and when the relation holds between three points A, B, C , the points are said to be "in the [linear] order ABC ."

O. Veblen's axioms and definitions, slightly modified, are as follows:

1. If the points A, B, C are in the order ABC , they are in the order CBA .

Dr. R. L. Moore (October 26, 1907) says this may be divided into parts, 1, inserting "distinct" before "points"; and 1₁, inserting "not all distinct," after "points."

2. If the points A, B, C are in the order ABC , they are not in the order BCA .

3. If the points A, B, C are in the order ABC , then A is distinct from C .

4. If A and B are any two distinct points, there exists a point C such that A, B, C are in the order ABC .

Dr. R. L. Moore modifies this to 4' by inserting "different from A and from B ," before "such." Then follow a definition, Def. 1, and axioms 5, 6, 7. Both in this definition, and in axiom 5 the shocking misprint occurs of using the symbol \pm , "plus or minus," for the symbol \neq , "is not equal to."

Dr. R. L. Moore had already in 1907 surprisingly simplified this set of assumptions by proving that 1₁ is a consequence of 2 and 5 and Def. 1, while 1₁ and 3 are both consequences of 2, 4', 5, 6, 7 and Def. 1.⁴

Lobachevski [or Bolyai] constructed the first explicit coherent theory of non-Euclidean geometry, and thus created a revolution in the philosophy of the subject. For many centuries the speculations of mathematicians on the foundations of geometry were almost confined to hopeless attempts to prove the "parallel axiom" without the introduction of some equivalent axiom.

⁴ *Trans. Amer. Math. Soc.*, Vol. XIII, No. 1, pp. 74-76.

In the Bibliography, Whitehead says of Lobachevski:

His first publication was at Kazan in 1826.

This is a mistake. In 1836 in his "Introduction to New Elements of Geometry," of which I was the first to publish a translation,⁵ he says:

Believing myself to have completely solved the difficult question, I wrote a paper on it in the year 1826: "Exposition succincte des principes de la Géométrie, avec une démonstration rigoureuse du théorème des parallèles," read February 12, 1826, in the séance of the physico-mathematic faculty of the University of Kazan, but nowhere printed.

No part of this French manuscript has ever been found. The latter half of the title is ominous. For centuries the world had been deluged with rigorous (!) demonstrations of the theorem of parallels.

Saccheri's book of 1733, containing a coherent treatise on non-euclidean geometry, of which I published the first translation, ended with another "démonstration rigoureuse du théorème des parallèles." If Saccheri had realized (as Father Hagen writes me he did) the pearl in his net, he could, with the new meaning, have retained his old title, Euclides ab omni naevo vindicatus, since the non-euclidean geometry is a perfect vindication and explanation of Euclid.

But Lobachevski's title is made wholly indefensible. A new geometry, founded on the contradictory opposite of the theorem of parallels, and so proving every demonstration of that theorem fallacious, could not very well pose under Lobachevski's old title. He himself never tells what he meant by it, never tries to explain it.

The title of Engel's book already given erroneously in the Bibliography under VI, is now, under VII, given again with the former and two additional errors.

After Riemann we see *Gesamte Werke* instead of *gesammelte Werke*.

In the title of Poncelet's work, on page 736, an accent is omitted which is given in the

⁵ "Neomonic Series," Vol. V., 1897.

same title on page 676, where on the other hand the main word of the title is omitted.

The Beiträge of von Staudt appeared in two parts, the first in 1856, the second in 1860. How could Whitehead have made the mistake of calling this second part a "3rd ed."?

GEORGE BRUCE HALSTED

GREELEY, Colo.

PEARL AND JENNINGS ON ASSORTATIVE CONJUGATION IN THE PROTOZOA

IN general, the scientist's investigations receive the recognition they deserve from his fellow workers. This is true because the bulk of research consists in the working out of details in a scheme already stamped with authority. It is the unexpected, fundamentally new or truly brilliant result upon which the doctors disagree.

One of the best illustrations is a paper in *Biometrika* for February, 1907. In the demonstration of the existence of an assortative conjugation or homogamy in *Paramecium* analogous to the assortative mating previously found by Pearson in man, Pearl seemed to some of us to have struck a rich vein hitherto passed over by all prospectors. Others thought differently. Pearl's assays were discredited. In America, at least one review was declined. In England, J. J. Lister illustrated¹ by Pearl's paper his warning to biometricians to be sure they have a problem which is "sound from the standpoint of biology before bringing a formidable mathematical apparatus into action for its investigation."

Open criticism like that of Lister was more easily met² than the general indifference largely attributable to the *odium mathematicum*. This is now in a fair way to be overcome by the results being announced by Jennings. If these, in their turn, are being received by zoologists with but lukewarm enthusiasm, the fact indicates merely that the work is in advance of its time.

His recent study of conjugation in *Para-*

¹ Lister, J. J., *Nature*, Vol. 74, pp. 584-585.

² Pearson, K., *Nature*, Vol. 74, pp. 465-466, 608-610, 635, 1907.

³ Jennings, H. S., "Assortative Mating, Variability and Inheritance of Size in the Conjugation

mecium must be considered in comparison with Pearl's pioneer paper.⁴

a. Differentiation of Conjugants in Type and Variability.—The general belief that conjugants are on the average smaller than non-conjugants is quantitatively substantiated. In eleven "pure lines" Jennings found conjugants to be from about 4 to nearly 14 per cent. smaller than the non-conjugants. In "wild" cultures, or in a mixture of differentiated pure lines, the mean for conjugants may be higher because only the large pure line is in conjugation. On the other hand, the conjugants may be abnormally small, 30 per cent. less than the non-conjugants, because only the smaller of the lines in the mixture is in conjugation.

Both absolutely and relatively, the conjugants are less variable than the non-conjugants. The difference in variability may be slight but generally it is large, for the conjugants are on an average about 33 per cent. less variable (relatively) than the non-conjugants.

The possible causes of this reduced variability are discussed. Lister's "Gametic Differentiation" is dismissed. Pearl's conclusion that equalization of individuals (undifferentiated or proconjugants) during the process of conjugation can not account for the lessened variability is confirmed. Jennings's conclusion, supported by abundant evidence, is that the low variability of conjugants is fully accounted for by the fact that conjugation does not occur till a certain growth stage has been reached, and does not occur in the largest individuals—the measurable variability of *Paramecium* being largely a growth phenomenon. Thus, the conjugants represent a definite and rather limited growth stage, the exclusion of both the larger and of *Paramecium*," *Journ. Exp. Zool.*, Vol. 11, pp. 1-134, July, 1911.

⁴ Pearl, R., "A Biometrical Study of Conjugation in *Paramecium*," *Biometrika*, Vol. 5, pp. 213-297, 1907.

⁵ The offspring of a single individual reproducing by fission has been called by Jennings a "pure line." In retaining the term here nothing more is implied than guaranteed purity of descent.

smaller individuals resulting in a pronounced reduction in variability. The growth factor may be in wild cultures supplemented by racial heterogeneity.

b. The Existence of an Assortative Mating.—Pearl's conclusion that there is a real assortative mating in *Paramecium* is backed up in every point by Jennings's more detailed study. Large individuals conjugate with large, small with small. Pearl's five series gave positive values of $r=.430$ to $r=.794$. Jennings's eight "wild" cultures of unknown racial composition all gave positive correlations of $r=.245$ to $r=.507$.

In twelve lots of conjugants from "pure races" with correlations ranging from $r=-.193$ to $r=.507$, there are ten positive and only two negative constants—both based on very small numbers and not statistically trustworthy with regard to their probable errors. The average of the twelve is $r=.251$. The correlation after separation of the pairs, is demonstrated to be greater than that determined on individuals which are united.

c. The Causes of the Assortative Mating.—Unquestionably, therefore, there is a real assortative conjugation. The redemonstration of the existence of a correlation between conjugants and the proof that it is not merely the result of heterogeneous cultures with only certain constituents in conjugation at one time is followed by a magnificent experimental-statistical analysis of the possible underlying factors. Equalization during mating, change of size during union, differential contraction due to killing fluid, environmental heterogeneity in the culture, are subjected to observation, experiment, measurement and statistical analysis. The specific results interest primarily the protozoologist. The broad and well-established conclusion is that the chief source of the correlation is, as Pearl five years ago maintained in *Biometrika*, a real assortative mating (larger individuals tending to conjugate with larger, smaller with smaller) arising in the fact that individuals must be of a certain degree of similarity in size to "fit."

d. The Evolutionary Significance of (a)-(c).—In connection with physiological differences resulting in different times of conjugation demonstrated by Jennings, the assortative conjugation is clearly a factor of the highest importance in the physiological isolation of the diverse races of *Paramecium*.

Apparently, the smaller size and lower variability of the conjugants have not a selective influence in maintaining the type of the population. The smaller extremes are, for the most part, younger than the conjugants, while the larger non-conjugants themselves conjugate after a few fissions. Moreover, the offspring of conjugants increase in size and in variability until they equal (or, in size exceed) the non-conjugants. Ex-conjugant offspring of individuals separated before completing conjugation.

Finally, the questions concerning the origin of heritable variations through conjugation within the "pure line," inextricably bound up as they are with the problem of the significance of conjugation, are reserved for a later paper. We are told, however, that heritable variations do, though rarely, arise as the result of conjugation within the "pure race."

Important as are the biological results of these two papers, their greatest value lies, not in concrete facts, but in their demonstration of the value of a widely applicable method. Let us hope they are only the beginning of the attack upon the many problems of morphology, physiology and genetics of the microorganisms which the biometric methods applied by Pearl and Jennings render possible.

J. ARTHUR HARRIS

"THE PASSING OF THE SLIME-MOULD'S"

ON the first page of a late number of SCIENCE, April 13, appears the heading of a brief note entitled "The Passing of the Slime-moulds," by Professor C. E. Bessey. One who reads no farther, having in mind such titles as "The Passing of the Buffalo," "The Passing of the Chinese Empire," etc., might possibly infer that the slime-moulds were doomed

to speedy disappearance if not already gone. But such would be a serious error: the case is not so bad as that. These beautiful organisms were never more abundant than, nor did they ever receive such intelligent attention as, at the present moment. If the reader will leave the title-page and turn to the article itself he may, by reading a sentence or two, perhaps conclude that the "passing" in question is limited to the transit of thoughts about slime-moulds in the mind of our honored colleague during some thirty years. This is of course a matter of interest. We are glad to learn Professor Bessey's view even if inconstant, concerning any topic whatsoever. But we are still too hasty of conclusion. The "passing" intended is something different yet. Read to its conclusion the article in question would have us know that, in the judgment of the author, slime-moulds have finally passed from botany to zoology, have ceased to be plants (?) and have become animals—good riddance to them! Now in so much as our colleague esteemed does not at all trouble himself to define for us a plant or even an animal, the reader is left wondering; there rises the unbidden query: if we do not *know* what they are, why not let them alone, at least until we do know something definitive?

It appears, however, from the article, that DeBary, some half century ago, concluded the slime-moulds were not plants. It appears further that nothing has been added to DeBary's argument until the recent appearance in the Encyclopædia Britannica of an article on the *Mycetozoa*, where these are set forth as animals for the mere reason that the author of the contribution so esteems them. Professor Bessey agrees. The whole thing is a matter of opinion; each of us, so far as stated reasons go, may think as he will;—and there you are!

But since the encyclopedia article has been forsooth the cause provocative in the present instance, it may be worth our while to note for a moment the inspiration of that particular essay, that we may better realize the full weight attaching to the opinion so consoling to our Nebraska author.

The writer of the 11th-edition article bears a distinguished name. He is a zoologist, a collaborator of Professor E. R. Lankester for whose "Treatise on Zoology," now appearing, the younger man wrote a chapter on the *Mycetozoa*. For the "passing of the slime moulds" so far, therefore, we are indebted to the English professor, and it is worth while reading the introduction to what is to be his masterpiece, no doubt, to his "Treatise," in order to completer information at first hand.

This introduction to have *raison d'être* at all must evidently show something new. It is fair to state that the only novelty discoverable, aside from a multitude of unnecessary and hybrid terms, consists in the amount of botany offered, both in the introduction and in volume one. In the introduction the independent life of the green plant is emphasized at length, as matter heretofore strange to the zoological reader. The "subtle process" by which green plants take up N in the form of *ammonia* will come as information to botanists as well; while the statement that the animal depends for food upon "hydrocarbons" ought to be news even to zoologists.

That the earliest plants are to be traced to flagellate colony-building protozoa, similar to the *Volvocineæ*—here reckoned animals, of course—is also a contribution to botany deserving grateful recognition. But it is admitted that certain organisms "devoid" of chlorophyll are plants. Here belong "fungi, bacteria and a few others."

Autonomous fungi and the saprophytes depend for their food on the products supplied to them by the chlorophyll-holding cells of green plants.

Finally, the summary of zoological wisdom in this remarkable discussion appears in the following elegant sentence:

The colorless or greenless plants are descended from green chlorophylligerous ancestors: mouthless, gutless animals are descended from mouth-bearing, gut-hollow animals.

Now as above stated, the encyclopedia man prepared a chapter on *Mycetozoa* to follow in Vol. I. this erudite introduction. The slime-moulds are protozoa and come in for the present, until better accommodations are at

hand, between the *Heliozoa* and the *Radiolaria*. This, of course, need make little difference. The slime-moulds are "mouthless and gutless" and should go anywhere with that set. From just which, however, of the "mouth-bearing, gut-hollow" creatures such graceful forms as *Arcyria* and *Lamproderma* have descended will no doubt be made clear on some future page!

Such is the sort and kind of finished scholarship with which it is now sought to align American botanists.

But really does it much matter where these things are placed? For 150 years they have been handled by the botanist. If they are now to go to the zoologist, or the chemist, he must show some reason for his claim. Some day, refined research, perhaps by methods not now devised, will show more clearly lines of descent and so of genetic kinship. That day is not here yet—so far, at least, as is to be learned from authorities herein cited.

Meantime, it may be said in conclusion, the great collections on which the Oxford professor and his pupils have so gratuitously toiled, still occupy probably an honored alcove in the *herbarium* of the British Museum.

SCIENTIFIC BOOKS

Meteorology, a Text-book on the Weather, the Causes of its Changes and Weather Forecasting, for the Student and General Reader. By WILLIS ISBISTER MILHAM. The Macmillan Company. 1912.

As the author of this latest treatise on meteorology is a most popular professor of astronomy in Williams College it is natural that this book shall bear all the characteristics of an admirable text-book for class use. It is also intended for the general reader. It starts at the beginning and must be intelligible to all, but it has abundant references to current literature for the use of those who wish to study further. The author has not attempted the history of the science, nor the relations of climate to disease or plants, nor has he

laden his pages with heavy mathematical work nor with a dozen other special items that would be included in an encyclopedic treatise. Professor Milham's book is simply an enlargement of the lectures which he has been giving for the last eight years in Williams College which aims to give its students a broad education in languages and sciences that have to do with our every-day life. The genial generosity of the author is shown by his painstaking acknowledgment of every authority from whom he quotes and one might imagine the book to be a compilation were it not for the many good ideas originating with the author. As a popular text-book it is admirable and fills a want distinct from that which is satisfied by the excellent work of Davis. After four hundred pages devoted to the atmosphere and the weather bureaus the author adds a hundred pages, as part two, devoted to the climate, the floods, electric, optic and acoustic phenomena.

The great utility of reliable forecasts has undoubtedly always been an incentive to all mankind and throughout all ages to apply our crude scientific knowledge to the study of the atmosphere, but since the days of Galileo the love of knowledge for its own sake—the love of research into the hidden things of nature has been a characteristic of civilized man. The conflict between darkness and light, the contest between superstition and intelligence, the fight between conservatism and progress has nowhere been so persistent as during the past forty years and in the field of meteorology. Professor Milham is quite correct in saying that there is no subject wherein ignorance and superstition are more nearly universal than in connection with the weather. Perhaps we can not blame the well-educated citizens for a certain amount of ignorance since so little is taught about meteorology either in high schools or colleges. Apparently another century must elapse before courses of laboratory experimentation have been devised for use in our higher schools of science.

Our subject begins with the constitution of the atmosphere considered as a mixture of several gases and vapors; these are warmed by

the sunshine and cooled by the radiation of heat; the upper layers of the atmosphere have both heat and moisture carried upward into them by convection, namely, by air that ascends from near the earth's surface: on the other hand the lower atmosphere is slightly cooled by the descent of an equivalent mass of the upper air. Of course radiation of heat from the atmosphere and the earth outwards goes on continuously, whereas convection is spasmodic; hence, the distribution of temperature is a regularity that is modified by many irregularities. The annual and the diurnal periods and the irregular variations of heat are appreciated by every one as is also its diminution with altitude. The barometric gradient is generally regarded as the cause of the motions of the atmosphere, but the rotation of the earth on its axis modifies these winds in such a way that northerly winds become northeast and southerly winds become southwest and so on around the circle. Of course the atmospheric pressure has its regular annual and diurnal variations and its irregular ones also, as well as its diminution with altitude. The regions of high pressure on the earth's surface are also regions of descending dry and dense air, whereas the regions of low pressure are those toward which the air is blowing and are the ordinary storm centers. The general circulation of the atmosphere is maintained by such barometric differences far above the earth's surface as well as at sea level: these are complicated with the large differences of the highs and lows of the barometric pressure that maintain our storm areas. The paths of these areas are shown by Milham in small maps prepared by several different persons—Bigelow, Van Cleef, Bebb, Loomis, Russell. The attempt to predict the path of any area of high or low pressure is the fundamentally difficult problem of the forecaster and is one to which considerable attention is given in Professor Milham's book. The volume is illustrated by 157 illustrations and fifty charts and a number of numerical tables. A brief summary shows that Milham's meteorology is a work destined to be eminently useful, both to the teacher and to

the general reader. The publishers have spared neither money nor pains in order to make this beautiful volume acceptable to the author, the teacher and the student.

C. A.

Probleme der physiologischen und pathologischen Chemie. Fünfzig Vorlesungen über neuere Ergebnisse und Richtungslinien der Forschung für Studierende, Aerzte, Biologen und Chemiker, von Dr. OTTO VON FÜRTH, A. Ö. Professor für angewandte medizinische Chemie an der Wiener Universität. I. Band, Gewebeschemie. Leipzig, Verlag von F. C. W. Vogel. 1912. Pp. xv + 634.

This is neither a systematic text-book, an encyclopædic compilation of facts, nor a mere epitome of current theories or methods—it is quite different from other recent publications in this field of science. Physiological chemistry has been the subject of an exceptionally large number of useful handbooks and comprehensive monographs on special topics, all published in very recent times and useful as works of reference. Here at length is a book which can not only be "tasted" or "swallowed," but even "chewed and digested," according to the Baconian classification. Assuming a familiarity with at least the elements of biochemistry on the part of every reader and making no pretense to cover the field with uniform completeness or comprehensiveness in every chapter, Professor v. Fürth has furnished a readable volume of refreshing novelty.

We are in danger, in present-day science, of becoming the slaves of system. These new lectures break away from some of the current tradition in respect to form and appeal to him who is not so much in search of organized literature as of inspiring viewpoints. The justification for this series of essays on the accomplishments and tendencies of the chemical physiology of these days—essays unhampered by the conventional text-book requirements—is well expressed by the author.

Ich vermag mich niemals eines Gefühles von Neid zu erwehren wenn ich zum Beispiel Briefe

von *Liebig*, *Wöhler* oder *Berzelius* lese und sehe, wie für diese Glücklichen jede wissenschaftliche Publikation ein Ereignis war. Mit welcher Liebe wurde alles, auch wenn es nur wissenschaftliche Kleinarbeit war, aufgenommen, mit welcher Freude wieder gelesen und überdacht. Wir laufen Gefahr, durch die Masse literarischer Produktion schliesslich das naive Vergnügen am Neuen einzubüssen und der Neugierde verlustig zu werden, die jedes ursprüngliche Individuum, ob jung oder alt, dem Unbekannten entgegenbringt und die schliesslich die Seele jeder echten Naturforschung ist. Und wenn heute in einem Fache, wie es die *Biochemie* ist, der Fachmann im Schweisse seines Angesichtes eben noch imstande ist, sich über die Literatur in ihren wichtigsten Erscheinungen einigermaßen zu orientieren, ist dies für den Fernerstehenden bereits längst ein Ding der Unmöglichkeit geworden.

The titles of the individual lectures are too diverse to be quoted here in detail. The treatment throughout is animated by the viewpoint of the physiologist, rather than the chemist. Chemistry is made to elucidate biological functions. The lectures can not fail to interest pathologist, therapist and surgeon as well as physiologist; for their problems are considered in common in a truly biological spirit well exemplified in a chapter on the thyroid. In a chapter on the kidneys, for example, the theories of secretion, the problems of uremia, the inadequate status of our knowledge of eclampsia, transplantation experiments, etc., are interwoven into suggestive relationships reminding one of how much still awaits solution. The critique of the author obviously can not always be equally forceful or correct; how trenchant it may at times become is illustrated by v. Fürth's comments in relation to eclampsia:

Für den Begriff eines "urotoxischen Koeffizienten," so schön und gelehrt dieser Name auch klingen mag, vermögen wir seinem Erfinder mit bestem Willen nicht dankbar zu sein.

It is unnecessary to proceed far in these lectures to discover that the author is something more than a compiler. He has studied physiological problems in the laboratory; and, as might be expected, the expert familiarity with certain phases of the subject betrays

itself advantageously in many places. For this reason, too, not all of the topics are treated with equal success. It is as gratifying as it is uncommon to find, in a European book, a thorough appreciation of the work of American investigators along physiological lines.

To one who enjoys the historical aspects of science the lectures will afford many entertaining reminders. There is a "subjective" tendency manifest throughout, which occasionally goes to the extreme of hyper-appreciation. The personal factor and individuality of the treatment crop out frequently in delightful "touches," a few of which may be quoted here. Speaking of the prolongation of life and the "sour milk" therapy of Metchnikoff:

Ist es doch das gute Recht der Menschheit, sich des grossen Allbezwingers mit allen ihr zugänglichen Mitteln zu erwehren, und es wäre sicherlich sehr erfreulich, wenn ein so einfaches Pharmakon, wie vergohrene Milch sich ihr als wirksames Kampfmittel erweisen sollte (p. 44).

For intermediary metabolism, we read, passt ein Bild, das einst ein geistvoller Mathematiker auf die Integralrechnung angewandt hat, um die unergründlichen Tiefen derselben seinen Hörern begreiflich zu machen. Er sagt, sie gleiche einem Meere, an dessen Ufern der Fischer immerhin das sammeln mag, was aus der Tiefe nach der Oberfläche dringt; doch vermag keines Menschen Auge die ganze Daseinsfülle zu ergünden, welche die abysischen Tiefen erfüllt (p. 46).

Note the attitude toward exploded theories:

Es dürfte aber vermutlich noch eine ganze Weile dauern, bis die Uroleucinsäure aus der physiologischen Chemie verschwunden sein wird; denn die Biochemiker zeichnen sich meist durch eine besondere Pietät gegenüber den Irrtümern ihrer Vorgänger aus. In der "reinen" Chemie pflegt man kürzeren Prozess zu machen und hält es nicht für nötig, in jeder Abhandlung die ganze Kette überwundener Irrtümer früherer Generationen von neuem abzuhaspeln (p. 52),

or again:

Es ist stets eine missliche Sache, wenn man über unklare Dinge eine klare Auskunft geben soll (p. 67).

Commenting on the superiority of certain

synthetic over the older natural products, he writes:

Ich fürchte fast, es würde manchem Teilstücke der Herrlichkeit klassischen Altertums ebenso ergehen, wenn man es mit der Exaktheit einer chemischen Synthese vor unseren Augen neu entstehen lassen könnte. Von dem alten Märchenglanze würde vielleicht nicht allzuviel übrig bleiben (p. 76).

The future possibilities of protein synthesis are introduced with these words:

Sowohl für junge Menschen als auch für junge Wissenschaften gehören Ideale zu den notwendigen und gesunden Lebenselementen, da ihnen die Fähigkeit innewohnt, latente Kräfte zu mobilisieren und nützlichen Zielen dienstbar zu machen, wenn auch die Unerreichbarkeit streng genommen zum Begriffe eines Ideales mit dazu gehört (p. 96),

whereas the older attempts are dismissed thus:

Dass wir auf diesem und auf ähnlichen Wegen zu wirklichem echten Eiweiss gelangen könnten, ist wohl nicht viel wahrscheinlicher, als wenn jemand einen Haufen Lettern in einem Sacke durcheinander mischen, sodann auf den Tisch ausschütten und nun hoffen möchte, dass dieselben sich zu einem schönen Gedichte gruppieren würden (p. 97).

That there is no attempt to hide our ignorance in certain fields is indicated in connection with internal secretion.

ein viel missbrauchtes Schlagwort, welches im Laufe des letzten Dezenniums zu einer gewaltigen Popularität gelangt ist. Dasselbe bezieht sich auf die Funktion einiger Organe, deren physiologische Rolle und Bedeutung, ungeachtet eines grossen Aufwandes von Mühe und Arbeit, in tiefes Dunkel gehüllt ist. "Denn eben wo Begriffe fehlen, da stellt ein Wort zur rechten Zeit sich ein;"—so sprach einmal ein weiser Mann, der zwar von "inneren Sekretionen" noch nichts ahnte, dafür aber über manche andere Dinge um so besser Bescheid wusste (p. 404).

The sources of the literature are indicated in a comprehensive way and the progress of research has evidently been followed up to very recent months. There is, as a rule, no irritating wealth of details; yet the essential steps in important reactions, such as the synthesis of suprarenin, are reviewed with painstaking accuracy. A second volume on metabolism is promised soon.

The publication of the lectures was the outcome, the author tells us, of a desire

meine eigene Freude an biochemischem Suchen und Erkennen anderen, die danach Verlangen tragen, zu übermitteln und auf diesem Wege meiner Wissenschaft zu dienen.

In this Professor v. Fürth has succeeded.

LAFAYETTE B. MENDEL

YALE UNIVERSITY

The Lower Cretaceous Deposits of Maryland.

By WILLIAM BULLOCK CLARK, ARTHUR B. BIBBINS, EDWARD W. BERRY and RICHARD S. LULL. Maryland Geological Survey. 1911. Pp. 1-622, pl. I.-XCVII.

This volume, the fourth of a series of exhaustive reports dealing with the systematic geology and paleontology of Maryland, is devoted to the Lower Cretaceous and is a distinct and invaluable contribution to the history of the Atlantic coastal plain geology of which the Maryland section may be taken as the type. The first hundred pages are devoted to the coastal plain region of the state and comprise a description of its physiographic features and a briefer statement of the Cretaceous, Tertiary and Quaternary formations, followed by a more detailed account of the areal distribution, lithologic character, stratigraphic and structural relations and organic remains of the three Lower Cretaceous formations involved. These, according to the nomenclature adopted, are, in the order of their superposition, the Patuxent, the Arundel and the Patapsco formations, together comprising the Potomac group. An especially valuable part of this portion of the volume is the historical review of opinion and the bibliography, for, be it known, the geology of Maryland has been the subject of much discussion and difference of interpretation. For example, the Patuxent and Arundel formations, on the basis of their contained vertebrates, were held by Marsh to be of Jurassic age, while the abundant plant-remains argued indisputably for their Lower Cretaceous age, a conclusion to which Professor Lull, who has reexamined the vertebrate material, has also come.

The paleontology fills the remaining five sixths of the volume and comprises reports on the Mollusca by Clark, the Vertebrata by Lull and the Plants by Berry. The molluscs are unimportant, consisting of only five species, all new, four of which are from the Arundel and one—a *Unio*—from the Patapsco. They are of little or no value in correlation.

The vertebrate fauna—found only in the Arundel—is much larger and consists of seven genera of dinosaurs, a crocodile, at least one turtle, and a ganoid fish. In discussing the affinities of the dinosaurs Professor Lull compares them with the Morrison of the west and the Wealden and Jurassic of Europe, concluding that “the weight of evidence would seem to place this fauna beyond the Jurassic into the beginning of Cretaceous times.” As the Arundel reptiles are closely related to, if not in some cases actually identical with, those from the Morrison of Colorado, their bearing on the age of the latter is of importance.

The major portion of the volume is devoted to the elaboration of the fossil flora by Mr. Berry. As a preliminary to the correlation of the Potomac flora he devotes a chapter to the “Lower Cretaceous Floras of the World,” in which is reviewed the plants of this age in Switzerland, Portugal, France, England, Belgium, Germany, Saxony, Africa, Peru, Japan, China and Spitzbergen, as well as the several approximately contemporaneous deposits in this country. Complete lists of the species occurring at each locality are given, and while no attempt has been made to revise the nomenclature or determinations, they furnish an exceeding valuable basis for correlative and stratigraphic comparisons. Following this is a chapter on the “Correlation of the Potomac Formations.” In this it is shown that the Patuxent and Arundel formations on the basis of their contained floras are essentially a unit of early Cretaceous age whose affinities all lie with the floras which preceded them, while the Patapsco, which was separated by a long time interval, has its strongest relations with the floras which followed it. The conclusion is reached that the Patuxent and

Arundel formations “considered as a unit represent all except possibly the earliest part of the Neocomian and all of the Barremian of standard European sections.” In this country it is believed to correspond in whole or in part with the Trinity of Texas, the Lakota of the Black Hills, the Kootenai of the Rocky Mountain region and the Cretaceous portion of the Knoxville of the Pacific Coast. The Patapsco is correlated with the European Albian and with the Fuson of the Black Hills. It is chiefly remarkable for the fact that it appears to have witnessed the introduction of the dicotyledons.

Over four hundred pages and seventy-five plates are devoted to the elaboration of the flora, which, according to Mr. Berry, comprises 144 species distributed among the several groups as follows: Filicales 43, Lycopodiales 1, Equisetales 2, Cycadophyta 33, Ginkgoales 1, Coniferales 29, Angiospermæ 25, of unknown systematic position 10. The treatment throughout has been conservative and rational, and has been based on all of the original material as well as a vast amount of recently and carefully collected material, with the result that the number of recognized species has been greatly reduced. Thus, Fontaine referred 42 species of ferns to the living genus *Thysopteris*, but these have been reduced to 5 and all referred to *Onychiopsis*. The number of species of *Cladophlebis* has been much reduced, as they have in the genera *Abietites*, *Sphenolepis*, *Arthrotaxopsis*, and especially *Sequoia*. A new generic type of fern, thought possibly to be referable to the Matoniaceæ, has been established for certain fronds of medium or large size and pseudo-dichotomous habit. Another fern, originally referred to *Baieropsis*, is shown clearly to be a member of the Schizæaceæ.

However, most biologic interest centers in the angiosperms, since they are as old as any of which we have definite knowledge. From the original descriptions and roughly prepared figures, it appeared that they were crude and archaic as befitted their first appearance, but with newer and better material and improved methods of reproducing them, they are seen to

be highly organized and surprisingly "modern" in aspect, thus showing that our knowledge of the actual starting point for this now dominant group is still imperfect. Mention may be made of a few of the more interesting forms. A small *Sagittaria*-like leaf is described under the new generic name of *Alismaphyllum*. What appears to be a fruiting sedge is included under *Cyperacites*, while under the name of *Plantaginopsis* is figured a plantain-like leaf and fruit possibly belonging to the Xyridales, which completes the list of monocotyledons. The dicotyledons are included under *Populus*, *Populophyllum*, *Nelumbites* (a very *Nelumbo*-like leaf formerly referred to *Menispermities*), *Sapindopsis*—the most abundant and important dicotyledonous plant of the time—*Celastrorphyllum*, a form-genus suggesting the Celastraceæ, *Sassafras*, quite closely approximating the living form, *Araliophyllum* and *Ficophyllum*, form-genera recalling *Aralia* and *Ficus* respectively, and a few others that are without very clearly understood living affinities. Altogether, the elaboration of the Lower Cretaceous floras of Maryland is of a high order, and Mr. Berry is to be congratulated on the completion and publication of the work which must long remain as a model of its class.

F. H. KNOWLTON

Woodland Idyls. By W. S. BLATCHLEY. Indianapolis, Ind., The Nature Publishing Co. 1912. Pp. 242.

Mr. Blatchley has again published a nature book, interesting, instructive, enjoyable. Just the kind of a book to take out on a summer vacation to impart the love of nature and her creatures and teach one the value of simple things. It is a chronicle of several vacations spent in the fields and woods, camping at night in a tent, by day fishing, watching birds and insects, and taking notes on the happenings around him. Mr. Blatchley is qualified to speak knowingly and scientifically of nature's secrets, by long years of investigation in various phases of zoology and botany. The specialist will find here many little notes on the habits of birds, fish, turtles, small mam-

mals and insects fresh from the mind of a careful observer. Like a clear, sweet, woodland brook, there runs through all a philosophic, yet optimistic strain of adaptation of human needs to the simplicity of nature.

N. BANKS

The Evolution of Animal Intelligence. By S. J. HOLMES. New York, Henry Holt. 1911. Pp. iii + 296. \$2.75.

Professor Holmes gives a rather popular presentation of some of the recent work in animal behavior. He does not pretend to make his treatment of the field of behavior at all complete. The subjects he treats at some length are as follows: tropisms; behavior of protozoa; instincts and their origin; pleasure, pain and the beginnings of intelligence; types of intelligence in crustaceans, mollusks, insects, lower vertebrates and mammals. The final chapter is devoted to the study of the mental life of apes and monkeys.

While most if not all of these subjects have received more skilful treatment in the hands of Jennings, Mast, Washburn, Yerkes and Thorndike, Holmes gives a readable presentation of certain phases of behavior which will be of service to students beginning the study of comparative psychology. The book's value lies in the readiness with which it lends itself to pedagogical purposes.

JOHN B. WATSON

JOHNS HOPKINS UNIVERSITY

Butterfly Hunting in Many Lands: Notes of a Field Naturalist. By GEO. B. LONGSTAFF, M.A., M.D., Oxon. Longmans, Green & Co. 1912. Pp. xviii + 724, with sixteen plates, seven colored. Price, \$7.00 net.

The author describes this work as "an attempt, possibly a foolish one, to put into a readable form the technical diaries of a wandering entomologist, and to entomologists alone it appeals." The reviewer is inclined to agree. After a chapter on early reminiscences, Dr. Longstaff devotes nearly five hundred pages to notes on his captures from 1903 to 1910, during which time he visited Canada, certain of the West Indies, Panama,

northern South America, South Africa, Algeria, Egypt and the Soudan, India and Ceylon, China, Japan, New Zealand and Australia. He very evidently collected vigorously, both by eye and by net, not confining himself to butterflies, notwithstanding the title. In fact the majority of the illustrations in this part of the book as well as many of the notes concern other insects. These notes are largely simple records of captures, leavened somewhat by random remarks concerning them or his traveling experiences. In view of the large amount of ground covered in so short a time, the lists of species for given localities are naturally too incomplete to be important and they must certainly detract from the interest of the narrative for non-entomologists.

The last chapter is based upon two papers by the same author in the *Trans. Ent. Soc. London* and is a summary of bionomic notes made chiefly by Dixey and the author on butterflies. The odor of many species is described; mutilated specimens are listed as having escaped from foes; peculiarities of flight and resting attitudes, including the selection of harmonizing backgrounds, are discussed, and the conclusions are orthodox neo-Darwinian.

The appendix consists of a translation of twelve of Fritz Müller's papers on the scent-organs of Lepidoptera. Six of these were published in Portuguese in the *Arch. do Mus. Nat. do Rio de Janeiro* where they have been inaccessible to many. The translations are by E. A. Elliott and the introduction to the appendix is by Poulton. The collection and translation of these papers will be a great help to students and it is well that they be read in connection with Longstaff's observations. However only the last chapter (and not all of that) is necessary for this purpose, and it does seem unfortunate that the rest of the book was not bound separately.

F. E. LUTZ

THE TALKING DOG

EXTENSIVE comment has been made in the German and even in the American daily press

on the reported conversational ability of "Don," a German setter seven years old, belonging to the royal gamewarden Ebers at Theerhutte in Gardelegen. Numerous observers reported that he had a vocabulary consisting of eight words, which he could speak if food were held before him and the following questions propounded: "Was heisst du?" "Don." "Was hast du?" "Hunger." "Was willst du?" "Haben haben." "Was ist das?" "Kuchen." "Was bittest du dir aus?" "Ruhe." Moreover, he was said to answer categorical questions by "Ja" and "Nein"; and in reply to another question, to speak the name, "Haberland." Among others whom popular report mentioned as witnesses to this extraordinary ability of the dog was Mr. Oskar Pfungst, of the Psychological Institute of the University of Berlin, whose important tests on the horse of Herr von Osten, "Der Kluge Hans," have lately been published in English.¹ Mr. Pfungst had in fact investigated the behavior of the dog in collaboration with Professor Vosseler and Dr. Erich Fischer, keeping detailed memoranda on the tests, and making a number of phonographic records. Partly to clear up misapprehension of his own position and partly for the enlightenment of the serious general public, he gave out a brief popular report of his work,² a summary of which appears below.

Having proposed three definitions of speech: first, properly, as the use of vocal sounds to convey to the listener an idea experienced by the speaker; secondly, more loosely, as the production of vocal sounds learned by imitation, but used without knowledge of their meaning to the hearer; and thirdly, as the production of vocal sounds not imitative of human speech, having no meaning to the speaker, but producing in the hearer illusions of definitely articulated, spoken words, uttered to convey meaning—Mr. Pfungst then asks to

¹ Pfungst, Oskar, "Clever Hans." Translated by Carl L. Rahn. New York, Henry Holt & Company, 1911.

² "Der sprechende Hund," von Oskar Pfungst (Berlin), Sechste Beilage zur Possischen Zeitung, 27 April, 1911.

which class the speech of Don properly may be referred.

First, it is plain enough that the dog does not use words with any consciousness of their meaning to the hearer. His vocabulary is always given in order, beginning with "*Don*" and ending with "*Ruhe*." If the order of questioning is varied he is called "*Kuchen*" and he desires "*Hunger*," etc. (Here it may be noted that the author was unable to get even approximations to the last three words in the list accredited to the animal.)

Secondly, it is evident, says Mr. Pfungst, that he is not using words learned by imitation. The author assumes that any imitator of another speaker would vary the pitch, intensity or accent of his words as the imitator's were varied. Don's voice—a high tenor, ranging from F on the bass clef to the octave above middle c, usually pitched in talking near d above middle c—is not varied when the pitch of the questioner's voice is altered. Furthermore he does not imitate changes in accent or intensity. He is as likely to say "*Kuchén*" as "*Kúchen*"; "*Hungér*" as "*Húnger*," etc. From the legitimacy of the author's adoption of this criterion, however, the reviewer is inclined to dissent. His own experience with a child of two and one half years, learning readily to speak a large number of words and phrases from imitation, and able to give both vowel and consonant values with perfect distinctness, for several months was that she would not imitate changes of intensity or pitch, although she usually showed apparent willingness to try. To apply this principle in the case of the dog would require the assumption of an attentive ability as well as of motor skill, far in excess of any of which that animal has given evidence. But Mr. Pfungst offers other disproof of the imitation hypothesis which to the reviewer seems adequate. This is found in the method of learning. The first word which the dog is reported to have uttered is "*Haben*." We are assured that being asked, "Willst du etwas haben," he thereupon pronounced distinctly the words, "*Haben haben haben*," and was rewarded with food for his pains. When he afterwards at-

tempted to pronounce the words he would give many inarticulate gurgles, but the food was given only when the correct number of syllables were uttered at once. The owner's family state that ten repetitions, some a week apart, sufficed for this learning. The word, "*Ruhe*," was first uttered after a command, "*Ruhe*," by the owner's daughter. Hearing the dog's response, she demanded, "Was sagst du da," and obtained again the answer "*Ruhe*." He was then taught to give this word after his fifth question, "Was bittest du dir aus?" The name, "*Haberland*," which none of the investigators could obtain from him, was first answered without instruction to the question, "Wer hat den ersten Artikel über dich in die Zeitung gebracht?" These facts are hardly consistent with any provable experience in learning by imitation. Indeed, it may be remarked that to the reviewer, who has spent the greater part of two years in experimentation on the behavior of dogs under controlled conditions, the animals' vagueness of perception and extremely low degree of attention would make a very strong presumption against the possibility of their learning even the simplest acts by "observation and imitation."

Mr. Pfungst concludes that the speech of Don is therefore to be regarded properly as the production of vocal sounds which produce illusions in the hearer. He calls attention to the fact that not even the number of syllables in any given "word" of Don's is constant. The dog makes only one vowel sound, having a value lying between *o* and *u*, varying considerably, but usually nearer *u*. The experimenters could not hear from him certainly either *a* or *e*. His one guttural-aspirant is like the German *ch*, and does duty for *k* and *h*. There is also a nasal, of a value lying between *n* and *ng*. When it is not prolonged it passes for a *d*, as in "*Don*." He really never makes the sound of *b*, *d*, *k*, *l* or *r*. When he utters a word expressed by [(*ch*)*unguo*], not much effort is required from a suggestible hearer to perceive the sound as "*Hunger*." When in making phonograph records the questioner asked merely "Was?", the dog gave

the customary answers, "Don," "Hunger?" "Haben haben," "Kuchen," etc., of which however only two out of sixteen answers were intelligible. Of 168 answers preserved on phonograph records, 71 per cent. were disyllabic and of the monosyllabic noises 68 per cent. were given when a considerable pause had elapsed between the last answer and this question. The "answers" were really incorrect fully as often as otherwise. Disinterested hearers could seldom distinguish his "Hunger" from his "Haben," nor his "Ruhe" from his "Kuchen," etc. It was as easy for others to perceive some of these same sounds as "Engelhof" or "Hallelujah"; "Huhn" or "Honig." Here it seems to the author we have a case quite parallel with our common interpretation of the night-swallow's call as "Whip-poor-Will" when in fact the sounds are nearly "Pfif-ah-rih"; and with the common German interpretation of their *Steinkanz's* "Kuwiit" or "Kuwiif" as "Komm mit," thus making him in popular superstition the messenger of death. But for a strong and uninhibited tendency thus to "apperceive" them, neither these calls nor the "words" of Don would be taken as other than meaningless noises.

On psychological grounds, Mr. Pfungst concludes, the explanation is comparatively simple; the uncritical do not make the effort to discriminate between what is actually given in perception and what is merely associated imagery, which otherwise gives to the perception a meaning wholly unwarranted; and they habitually ignore the important part which suggestion always plays in ordinary situations.

Accepting this explanation as satisfactory we may expect the majority of animal lovers to continue to read their own mental processes into the behavior of their pets. Nor need we be astonished if even scientists of a certain class continue at intervals to proclaim that they have completely demonstrated the presence in lower animals of "intelligent imitation" and of other extremely complicated mental processes—inferred from the results of brief and lamentably superficial

tests, and published as proven facts without further reflection.

HARRY MILES JOHNSON
THE JOHNS HOPKINS UNIVERSITY

FOURTH LIST OF GENERIC NAMES FOR
THE "OFFICIAL LIST OF ZOOLOGICAL
NAMES," PROVIDED FOR BY THE
GRAZ CONGRESS

15.¹ The following generic names of Diptera are proposed for inclusion in the "Official List of Generic Names." The species mentioned are the correct types, according to Coquillett, 1910.

Anopheles Meig., 1818, 10, type *bifurcatus*.
Anthomyia Meig., 1803, 281, type *Musca pluvialis*.
Chrysops Meig., 1800, 23, type *cæciens*.
Corethra Meig., 1803, 260, type *Tipula culiciformis*.
Culex Linn., 1758a, 602, type *pipiens*.
Cuterebra Clark, 1815, 70 type *Æstrus cuniculi*.
Gasterophilus Leach, 1817, 2, type *Æstrus intestinalis* (cf. *Æ. equi*).
Hæmatobia St. Farg. & Serv., 1828, 499, type *Conops irritans*.
Hippelates Loew, 1863, 36, type *plebejus*.
Hippobosca Linn., 1758a, 607, type *equina*.
Hypoderma Latr., 1818, 272, type *Æstrus bovis*.
Lucilia Desv., 1830, 452, type *Musca cæsar*.
Musca Linn., 1758a, 589, type *domestica*.
Muscina Desv., 1830, 406, type *stabilans*.
Nycteribia Latr., 1796, 176, type *Pediculus vespertilionis*.
Æstrus Linn., 1758a, 584, type *ovis*.
Ophyra Desv., 1830, 516, type *Anthomyia leucotoma*.

Phora Latr., 1796, 169, type *Musca aterrima*.
Piophilæ Fall., 1810, 20, type *Musca casei*.
Psorophora Desv., 1827, 412, type *Culex ciliatus*.

17. These names are published herewith for the information of all persons interested. They will be forwarded by July 1, 1912, to the International Commission on Zoological Nomenclature, the Commission on Nomenclature of the International Entomological Congress and to several entomological committees and societies.
18. A vote will be called on these names at the next meeting of the International Commission on Zoological Nomenclature, in the summer of 1913, and any objection to the proposed action should be filed with the under-

signed, and stating ground for the objection, not later than May 1, 1913.

C. W. STILES.

Secretary International Commission
on Zoological Nomenclature

SPECIAL ARTICLES

ENOOTHERA NANELLA, HEALTHY AND DISEASED

IN my cultures of the evening primrose of Lamarck, the pure and self-fertilized seed yearly produces a certain percentage of mutants, among them dwarfs, *Oenothera nanella*, the number of which usually amounts to about 1 per cent. of the whole crop. Of late, these dwarfs have been the subject of some discussion, since Zeylstra discovered the presence of a bacterium in their tissues and showed that some of their characters, formerly considered as specific marks, are, in reality, abnormalities caused by this parasite.¹ From this, some authors have erroneously concluded that the dwarfs are no real mutants, but only diseased individuals of the original type.²

Zeylstra, however, had pointed out that, under favorable conditions, the sideshoots of the dwarfs may become healthy and lose their abnormal characters; but their height remains the same as in the diseased stems. Hence we may assume that, under still more favorable conditions, the main stems themselves might grow up healthy, while still retaining the dwarfish stature.

About half a century ago, Liebig pointed out that nitrogenous manure is apt to increase the sensitiveness of plants to diseases, whilst phosphate of calcium is one of the best means to diminish this predisposition. Laurent found the same to be true for such diseases as are caused by those common bacteria of the soil, which, under normal conditions, are harmless, but may injure the cultures, whenever the manure is too rich in nitrogenous substances. He studied *Bacillus fluorescens putidus* and *B. coli communis*, both of which destroy the cellwalls by means of their enzymes,

¹H. Zeylstra, "Fzn. *Oenothera nanella* de Vries, eine krankhafte Pflanzenart," *Biolog. Centralblatt*, 1911, Bd. XXXI, pp. 129-139.

²Sammelreferat by G. Tischler, *Zeitschr. f. ind. Abst.*, 1911, Bd. V., p. 327.

even before they themselves reach the cells. The bacterium of *Oenothera nanella* is of a wholly different type, since it is found within the living cells and changes their growth without killing them. Zeylstra provisionally placed it in the group of *Micrococcus*.

From these data it is probable that healthy *O. nanella* might be obtained by giving them less nitrogen and more phosphate of calcium. Unfortunately, however, the nitrogen manure acts as the strongest stimulant, under our climate, to induce them to become annual, and for many reasons it is most desirable to have cultures of annual generations. It is, therefore, necessary to determine the amount of nitrogen and phosphate of calcium which will induce a sufficiently large percentage to become annual, but will not essentially heighten their liability to become diseased.

In the summer of 1911, I made some provisional experiments which show that, by this method, there may be produced almost wholly healthy specimens with the normal stature of the dwarfs. In the first place, I found that every part of the stem, every single leaf and flower, may be normal or diseased, in response to external influences. In the young rosettes of rootleaves the first leaves were formerly always twisted; then came long-stalked normal ones and, after these, the really abnormal leaves with broadened and shortened bases, which often killed the terminal bud before it could make a stem. By giving a large amount of phosphate of calcium, and as little nitrogen as possible, every one of the rootleaves could be grown healthy, with a stalk and a narrow wedge-shaped base. The same was the case with the leaves of the stem, and even with the flowers. The number of the abnormal ones could be brought down to a very few, thereby giving the whole plant the appearance of a healthy condition. All transitions between diseased and normal dwarfs were to be seen in these cultures.

Moreover, I have won beautiful healthy dwarfs by means of a cross from which the other parent was eliminated after the rule of the sesquicreprocal crosses.³ I pollinated a

³"Ueber doppeltreciproke Bastarde," *Biol. Centralbl.*, 1911, T. 31, pp. 97-104.

dwarf of *O. nanella* \times *biennis* with the pollen of an ordinary *O. nanella* and got a culture of *O. (nanella* \times *biennis*) \times *nanella* = *O. nanella* which contained a high percentage of healthy plants. They began flowering when only 20 cm. high, the first flower appearing at a height of 10 cm.; whilst *O. Lamarckiana* reached 1.50 m. before flowering, the first flower opening about 80 cm. above the soil. All their leaves were as narrowly elliptical and as clearly stalked as those of the *Lamarckiana* itself, whilst the flowers were free from those abnormalities which usually accompany the dwarfish stature.

Thus we see that the discovery of Zeylstra, far from diminishing the value of *Oenothera nanella* as a real and (in an experimental way) most useful mutant, has given the means of cultivating it in as healthy a condition as may be required.

HUGO DE VRIES

BEHAVIOR OF SPERMATOOA IN PLASMA

THE recent article of Loeb and Bancroft¹ and of De Meyer² in which their observations upon the behavior of spermatozoa in various sorts of solutions, such as extracts of eggs of the same species (De Meyer, eggs of *Echinus microtuberculatus*; Loeb and Bancroft, eggs of the common fowl), colloids, acids, alkalies, hypo- and hypertonic solutions, egg-albumen, blood serum and Ringer solutions are described open up a most interesting field for investigation. During the past summer while occupying a table at the Marine Biological Laboratory, Woods Hole (for the use of which I am indebted to Professor F. R. Lillie), I attempted to grow spermatozoa of *Arbacia punctulata*, *Mytilus edulis* and *Modiolus modiolus* in various solutions, some of which being listed above as used by these other workers.

¹ *Journ. Exp. Zoology*, 12: 381.

² *Arch. Biol.*, 1911, Bd. 26, H. 1, pp. 65-97: "Observations et expériences relatives à l'action exercée par des extraits d'œufs et d'autres substances sur les spermatozoïdes." I have seen only Robert Lewin's review in the *Zentralb. für Biochemie und Biophysik*, XII., No. 19/20, of De Meyer's paper.

On August 2, I centrifuged *Limulus* blood plasma and made a hanging drop from the upper layer, which examination showed to be free from cells; into this drop I introduced a few sperms from *Arbacia*. Great difficulty was experienced in attacks of bacteria and many of the preparations were discontinued the following morning. The slides were sealed with vaseline, as in the usual culture mount, and left at room temperature. By the eighth of August there was no movement in the sperms, although it had persisted up until that time and therefore the copper component of the blood of this animal does not seem to be toxic for *Arbacia* sperms, but none of the phenomena about to be described from mounts in different media were observed.

On August 5, a culture was made in the sterile agar medium, made according to the customary bacteriological formula, diluted so that it was liquid but highly viscid at 20° C. The spermatozoa lived only a short time and were seen to disintegrate within 24 hours. It may be stated that the reaction of the agar was estimated only roughly by an indicator and not titrated, so that I am not certain whether the medium was suitable from this standpoint. Care was taken to render the sea-urchins as free from bacteria as possible, the tests being washed off with HgCl₂, 1:1,000 before the cuts were made and sterile sea-water was used to receive the testes after extirpation. The mounts remained sterile throughout the time of observation, showing that the testes are bacteria-free, as one would suspect.

The plasma of a Norway rat was then tried on August 8 and this was prepared by centrifuging the blood of the rat in paraffin-lined tubes at about 8°-10° C. The plasma clotted when the hanging drop was made at room temperature, but sufficient time elapsed before the plasma clotted for the introduction of the sperm. The behavior of the sperm-heads was discovered to be quite like that described by Loeb and Bancroft for the sperm of the fowl, for the heads enlarged, became less dense, and distinct chromatin granules were visible, even in unstained preparations, resembling the nuclei of the spermatids of certain insects

which I have observed in a living condition without stains, the appearance being in this case checked with stained preparations. The sperms were active and the head and tail wriggled in their characteristic manner as long as they were visible. The tail became shorter and shorter as the head swelled, but in none of my specimens did the tail-cytoplasm completely incorporate itself into the head. This is true, I believe, for Loeb and Bancroft's experiments. In other words, a completely rounded out cell, like a spermatoocyte, did not appear in these preparations.

De Meyer succeeded in causing the heads to swell by growing the sperms in a dilute solution of gelatin (*gelatin sol*); every indication pointed to the perfect imitation of the formation of the pronuclear condition in a normally fertilized egg. It is of the greatest interest, too, to observe that the experiments made by De Meyer in acid solutions gave exactly the same result as colloidal solutions in general—that is, a swelling in acid media.

These experiments and those of Loeb and Bancroft show the possibility of approaching the explanation of the behavior of the spermatozoon during fertilization upon physical-chemical grounds. Factors leading to mitosis should be determined and the various artificial parthenogenetic reagents should be tried.

I have recently determined, also, that if a trace of saponin be added to the water in which the spermatozoa of *Cerebratulus* lie, there is a slight cytolysis and swelling of the head of the spermatozoon, but the "tail" is not affected, apparently. Whether mitosis can be induced in this manner, as it can in the egg, in the formation of polar bodies, as I have elsewhere described, remains yet to be determined.*

MAX MORSE

TRINITY COLLEGE,
HARTFORD, CONN.,

*I am under obligation to the officers of the biological laboratories of Yale University, Professors Harrison, Coe, Woodruff and Petrunkevitch, for the opportunity to study living nemertean eggs and sperms.

SOCIETIES AND ACADEMIES

RESEARCH WORKERS IN EXPERIMENTAL BIOLOGY, WASHINGTON, D. C.

At the meeting of this society, held on February 21, 1912, Dr. William N. Berg, of the Bureau of Animal Industry, gave a critical exposition of Zuntz's theory in regard to the physical-chemical basis of striated muscle contraction,¹ in which it was pointed out that this theory had many objectionable features. These may be summarized briefly as follows:

(a) Lymph contains practically no carbon dioxide in the gaseous state.

(b) Gases dissolved in water do not behave entirely like true solutes, and exert no osmotic pressure; exceptions are hydrochloric acid, ammonia and a few other gases.

Accordingly, the carbon dioxide produced by muscle contraction can not exert any osmotic pressure, and, furthermore, it is not shown in Zuntz's work that the walls of the muscle rods are impermeable to carbon dioxide during the contraction phase. This is necessary, for otherwise osmotic equilibrium could not be brought about by the inflow of water alone; an outflow of carbon dioxide must take place. A further objection is that carbon dioxide at the moment of its formation does not have a temperature of nearly 6000° C.

At the March meeting, held on the 20th inst., Dr. William Salant, chief of the pharmacological laboratory of the Bureau of Chemistry, gave a brief résumé of the caffeine investigations which were conducted in the Department of Agriculture, and which embrace studies on the effects of different amounts of caffeine upon the organism, with especial reference to the production of acute and chronic intoxication. Other factors, such as the influence of diet, age, season, etc., were considered.

In conjunction with the tests, which were done with carnivorous and herbivorous animals, the rate of demethylation of caffeine and the elimination of caffeine in the urine and gastro-intestinal canal were noted under normal and pathological conditions.

In addition to the above, the results of experiments upon the effect of caffeine upon the circulation, with particular regard to synergism and the antagonism of other drugs, were reported.

LEWIS W. FETZER

¹"Die Kraftleistung des Tierkörpers; eine Festrede," Kgl. Landw. Hochschule Berlin, 1908.

THE HELMINTHOLOGICAL SOCIETY OF WASHINGTON

THE eleventh regular meeting of the society was held at Mr. Crawley's residence on April 16, 1912, Mr. Crawley acting as host and Dr. Graybill as chairman.

In connection with Dr. Ransom's notes on cysticerci, Dr. Cobb called attention to a remarkable case of hydatid disease in Australia, where a man who had had a considerable part of the liver removed, owing to a hydatid infestation, subsequently returned for operative removal of another hydatid. It was found on operation that the second parasite was in another part of the liver and that there had been a practically complete regeneration of the excised portion of the liver.

The evening was devoted to the exhibition and discussion of apparatus, drawings and specimens by Dr. Cobb.

A set of screens for collecting free-living nematodes was shown, the screens being oblong instead of circular, and therefore easier to pack in a suitcase in field work. Two screens using a detachable silk bolting-cloth, instead of an attached brass-wire screening, have a new fastening device consisting of a string looping around projections from the tins. A wooden container for holding collecting bottles fits inside of the screens and of some collecting trays of the same shape as the screens.

Dr. Cobb remarked that he had secured superior results by using sea water in his sublimate fixing reagents, nematodes staining very much better after such treatment. He suggested that this might be due to traces of various chemicals in the sea water, rather than to an increased solubility of the sublimate used.

In connection with a number of specimens and drawings of nematodes, Dr. Cobb pointed out that there is a possibility that some of the free-living forms will be found to show traces of internal segmentation in the arrangement of the internal organs and their relation to the external markings. In an undescribed genus he noted the association of a strong buccal spear with a weak pharyngeal suction bulb, and surmised that the retrorse annulation in this form served to hold it in a tangle of vegetation so that the buccal spear could be used effectively in the absence of a strong suction bulb to fix the mouth in using the spear. In this genus the buccal spear is lost by the male in an ecdysis.

Dr. Cobb expressed the opinion that the study of nematodes will have to be separated from para-

sitology or helminthology as covering a field of size and importance equal to that of such subjects as entomology. The nematodes make up an isolated group with a very wide range of morphological structure, life history, habits and geographical distribution. The group includes parasites of vertebrates and invertebrates, parasites of plants on land and in water, free-living forms that eat vegetable matter, some that feed exclusively on diatoms, some that feed on bacteria and some that eat other nematodes. Broadly speaking, the mouth parts show the same general lines of variation that insects show, some being adapted to biting, others to sucking or stinging, and it is possible that the buccal stylet of *Mononchus* serves as a poison fang to benumb the nematodes on which this genus feeds. The life histories and methods of reproduction are very variable and include parthenogenesis. Nematodes occur in the soil and in the ocean in immense numbers and have been found in the polar regions. There are probably as many species as there are of insects, and some of the well-marked genera will probably be found to have as many as 500 species.

Some of the nematodes, such as *Streptogaster*, have an anterior dilatation of the intestine which appears to be morphologically and physiologically a stomach.

Dr. Cobb gave an interesting demonstration of the method of obtaining the decimal nematode formula, showing that it could be obtained with no great effort in about six minutes.

MAURICE C. HALL,
Secretary

AMERICAN PHILOSOPHICAL SOCIETY

ON April 12th, Dr. Willis F. Manges, Röntgenologist to the Jefferson Medical College Hospital of Philadelphia, read a paper before the American Philosophical Society on the X-rays. He reviewed briefly the history of the discovery and especially noted the great progress in safety and efficiency of the apparatus and methods of to-day as contrasted with the earlier results. By means of the modern methods of protection, X-ray injury is now almost entirely eliminated. He discussed the value of the X-rays in medicine and surgery both in diagnosis and treatment. He pointed out also that interpretation of the Röntgenographs required special skill, which could only be gained by a wide experience or careful training and that there was danger in their indiscriminate use in medico-legal cases because of the difficulties of such interpretation.

THE problem of heredity has been attacked in four principal ways. Galton developed to a high degree what we may call the statistical method. His most important conclusions are embodied in his law of ancestral inheritance and his law of regression. According to the former, the two parents together contribute one half of the total inheritance of an individual, the four grandparents one fourth, the eight great-grandparents one eighth, and so on indefinitely. The law of regression attempts to state the average deviation of a fraternity from the mean of the general population in terms of the average deviation of the two parents. Recent investigations have shown that neither of these laws is true except for averages of large numbers of cases, and not in all cases even then. They are not applicable to individual cases, and are hence of no importance in the modern science of genetics, however important they may be in statistical problems in general.

In recent years the methods used by Galton have been developed by Pearson and others into a highly mathematical treatment of the subject of heredity, which has given us important means of dealing with the precision and reliability of data and enabled us to study certain types of correlation to advantage, but which has otherwise had comparatively little influence on the progress of genetics. The study of correlation between hereditary characters by statistical methods has not as yet led to

¹MEET, intended for publication and books, etc., intended for review should be sent to the Editor of SCIENCE, Garrison-on-Hudson, N. Y.

¹Presidential address before the Washington Botanical Society, March 5, 1912.

discoveries of any great usefulness in the work of producing new and improved races of plants and animals, however useful it may have proved in other directions, or may yet be in genetics.

Another method of study has been that of the cytologist. A long list of able investigators have in recent years given attention to the phenomena of cell division, especially the process by which gametes, or reproductive cells, are produced. Very soon after the rediscovery of Mendel's principles cytologists pointed out that the behavior of the chromosomes in the reduction division is sufficient to account for Mendelian phenomena if a proper connection between the chromosomes and Mendelian characters could be proved. One of the most important results achieved in this line of investigation is the demonstration of a relation between certain chromosomes and the determination of sex. The work of Professor E. B. Wilson has been especially convincing in this respect, though many other investigators, especially Professor Morgan and Miss Stevens in this country, and Boveri, Baltzer and others in Europe, have contributed important results. The net results of these investigations are that in most species the female possesses a pair of chromosomes of peculiar character, usually distinguishable from the other chromosomes, and, because of their behavior in the prophase of the first maturation division, called by many cytologists "idiochromosomes." The male has only one of this type of chromosome. From the behavior of these idiochromosomes it results that all the eggs contain one idiochromosome, while the sperm is of two kinds, one containing a single idiochromosome, the other none. Eggs fertilized by the former produce females; by the latter, males. In a few species the female has only one of these peculiar chromosomes,

while the male has none. In these species the female produces two kinds of eggs, one female-producing, the other male-producing; while the male produces only one kind of sperm. These investigations have thus given strong reasons for believing that sex is an inherited character, and is hence not determined by external conditions.

These facts have been demonstrated for a large number of species (over a hundred), including man.

While in most species the male possesses but one of these presumably sex-determining chromosomes, it frequently happens that this chromosome has a synaptic mate, which, however, appears not to be concerned in sex production. This synaptic mate consists in some cases of a single chromosome; in others it consists of a group of chromosomes varying in number from 2 to 5 in different species; in still others it is wanting entirely. These facts are of special interest in connection with the further fact that a large number of ordinary somatic characters have been found to form Mendelian pairs with the sex element. Thus, in barred Plymouth Rock poultry the barring of the feathers is transmitted by the female only to her male offspring. Many human affections are transmitted in a similar manner, such as night blindness, color blindness, etc. Pearl has shown that high egg-laying quality in poultry is similarly sex-limited. Females do not transmit this quality to their daughters, but do transmit to their sons the power of transmitting to the granddaughters high egg-laying quality. A long list of such sex-limited characters has been demonstrated. These facts raise the presumption that these sex-limited characters are related to the chromosomes—in what manner of course we do not know.

On the history of the chromosomes during the life history of the cell, especially

during the events immediately preceding the metaphase of the reduction division, cytologists are somewhat divided on matters of fact. They are in essential agreement so far as the genetic continuity of the chromosomes is concerned, *i. e.*, they believe that each chromosome is directly descended from a previous one. There are cases, however, where the propagation of the chromosomes is not a simple matter of division in which all the substance of the old body passes directly into the two new ones formed from it by division.

The manner of formation of bivalent chromosomes in the early stages of the reduction division is still a matter of dispute, as is also the possibility or probability of exchange of substance between synapctic mates. A review of the work on this subject would be highly interesting, but would extend this paper beyond all reasonable limits.

Recent work has shown that many chromosomes are really compound bodies, and that what we have regarded as independent chromosomes are, in some cases at least, really groups of chromosomes. This fact may have an important bearing on partial or even complete correlation between hereditary characters, as well as the fact that in some species more Mendelian pairs have been demonstrated than there are pairs of chromosomes.

A third type of investigations relating to heredity is the study of the chemical processes concerned in development. A great deal of the work of the physiological chemist has a bearing on this subject, though not instituted directly for this purpose. This study has led to the conclusion, as Guyer states, that at least a principal function of the chromatin is the production of enzymes which, by their regulating effects on metabolic processes, produce important effects in the development of the

organism. Recently Gortner, of the Carnegie Institution, and Miss Wheldale, of Cambridge University, have attempted to work out the chemistry of certain of the pigments, with important results. For instance, Gortner has shown that, in the potato beetle, oxidizing enzymes are generally present in the body, while chromogen, which these enzymes convert into pigment, is produced locally in the integument in small quantity, and only in those locations where the characteristic pigment spots occur. One of our own members, Dr. Bartlett, is now doing some interesting work on the chemistry of anthocyan, and has become greatly interested in this phase of heredity investigations. Such investigations relate, of course, to the manner in which the hereditary characters make their appearance in development, not to the transmission of these characters.

This phase of heredity investigations is, as yet, only in its infancy. It is, however, one of the most important at the present time, for we can not go a great deal further in the interpretation of the phenomena of heredity until we know more of the chemical processes involved in the development of a complex organism from the fertilized egg.

Lastly, we come to the study, by experimental cross-breeding, of the behavior in inheritance of the various characters which distinguish nearly related organisms from each other. If relative importance were to be judged solely by the amount of data accumulated, this would be by far the most important phase of the subject before us. Here we have a plethora of fact and a dearth of meaning. We have now reached a point in the study of Mendelian inheritance where satisfactory interpretation of fact is quite as important as the collection of more facts. We need stimulating theories that will point out new directions for

research. When Mendel's laws were rediscovered practically simultaneously in the closing year of the last century, by de Vries, Correns, and von Tschermak, biology received such a stimulus as it has not felt since the publication of the "Origin of Species" in 1859. But what was it that gave this stimulus? Was it the collection of facts? Was it the wonderful collection of facts regarding variation made by Darwin that electrified the scientific world in 1859? Or was it a satisfactory interpretation of these facts? Darwin gave his facts *meaning*. Similarly, it was an *illuminating interpretation* of facts that made an epoch in the development of biological science when Mendel's principles were rediscovered. The fact that this discovery lay unnoticed for a third of a century and then suddenly became the leading interest of biologists is a remarkable commentary on the relation of science to human welfare in the last century and in the present.

The leading principle discovered by Mendel was that a hybrid whose parents differ in respect to a single factor of development, produces two kinds of gametes, respectively like the gametes of the two parents. This is now known as the law of segregation. In the early years of the present century genetic investigations dealt mainly with the universality of this law. This question is now practically settled, so far as can be by experimental cross-breeding. We now have a vast amount of data which need further interpretation that will point the way to new *kinds* of facts. The mass of data which has accumulated during the past dozen years has been variously interpreted by different investigators. It has furnished an extensive vocabulary of new terms, to which various meanings have been attached. Some recognized authority has suggested a new view concerning the nature of the so-called "unit-characters,"

and this view has been widely accepted with no critical examination of its intrinsic merits. The weight of authority here, as elsewhere, has been an incubus on the progress of scientific interpretation.

Mendel himself did not make use of the term "unit-character," but refers the phenomena he observed to *differences between formative elements* in the cells of hybrids. This is made clear in the following quotation from his original paper:

With regard to those hybrids whose progeny is variable we may perhaps assume that between the differentiating elements of the egg and pollen cells there occurs a compromise, in so far that the formation of a cell as foundation of the hybrid becomes possible; but nevertheless the arrangement between the conflicting elements is only temporary and does not endure throughout the life of the hybrid plant. Since in the habit of the plant no changes are perceptible during the whole period of vegetation, we must further assume that it is only possible for the differentiating elements to liberate themselves from the enforced union when the fertilizing cells are developed. In the formation of these cells all existing elements participate in an entirely free and equal arrangement, in which it is only the differentiating ones which mutually separate themselves. In this way the production would be rendered possible of as many sorts of eggs and pollen cells as there are combinations possible of the formative elements. . . . The differentiating characters of two plants can finally, however, only depend upon differences in the composition and grouping of the elements which exist in the fundamental cells of the same in vital interaction.

Thus instead of "unit character" Mendel speaks of "differentiating characters," and instead of pangenes in the germ plasm he speaks of "formative elements," differences in which are responsible for the differences in related organisms. Nowhere does he advance the idea that the germ plasm is composed of independent elements, each of which is responsible for the development of a definite portion of the organism. The latter idea is due to de

Vries. Until within the last two or three years the de Vriesian interpretation of Mendelian phenomena has been widely accepted, especially in England and in Germany. Generally speaking, American biologists have hesitated to accept the de Vriesian doctrine, preferring to regard the developed organism not as a structure composed of definite elements independent of each other in hereditary transmission, but rather as a complex resultant of the interaction of various cell elements no one of which is wholly responsible for any definite part of the organism.

In consonance with the de Vriesian conception, the idea early developed that the organism is a collection of "unit characters" arranged in pairs, any one of which might be replaced by certain others. Bateson, in 1901, in presenting to the Royal Horticultural Society a translation of Mendel's original paper, uses the following words:

In so far as Mendel's law applies, therefore, the conclusion is forced upon us that a living organism is a complex of characters, of which some, at least, are dissociable and are capable of being replaced by others. We reach thus the conception of unit-characters, which may be rearranged in the formation of the reproductive cells.

This is the first use of the term unit-character the writer has been able to find. The idea that hereditary characters are indivisible units is, however, due to de Vries. In de Vries's original paper on the law of segregation he remarks:² "According to the principles which I have elsewhere announced (Intracellular Pangenesis), the specific characters of organisms are composed of units quite distinct"; and, again, "for the simple character must be considered as an individual unit." The term "unit-character" did not come into

general use until about 1905 or 1906. The fact that it presented a conception easily apprehended, and the further fact that this conception lends itself readily to a convenient system of symbols for representing the phenomena concerned, led to the rapid adoption of the new phraseology even by those who reserved their opinion as to the philosophy on which the idea was based.

We have already seen that Mendel himself referred the phenomena he observed to differences in formative elements in the germ plasm, which were "in vital interaction." The de Vriesian philosophy, on the other hand, did not place much stress on this vital interaction, but looked upon each hereditary character of the organism as the expression of a particular element in the germ plasm which was, more or less independently of all others, responsible for the development of that character. A pair of segregating characters, such as smoothness and wrinkling in pea seeds, was looked upon as due to a corresponding pair of pangenes in the germ plasm, one of which, if allowed free action, would produce smoothness, the other wrinkling. Bateson's term *allelomorph* was generally used to refer to these hypothetical organs in the germ plasm, rather than de Vries's original term *pangene*, since the former term could be applied to the visible characters themselves as well. Later, when certain non-contrasting characters were found to segregate from each other, Bateson gave this phenomenon the name "spurious *allelomorphism*." An example already given of such a pair of segregating characters which are not contrasted characters is femaleness and the barring of the feathers in Plymouth Rock fowls; this means that when the reduction division occurs one of the resulting cells carries the potentiality of femaleness, the other that of producing bars on the feathers. Many other instances

²I am indebted to Dr. Geo. H. Shull for the following citations relating to the history of the unit-character conception.

of such pairing of unrelated characters are known in both plants and animals.

About 1903 a new conception of the pair of allelomorphs arose. In that year, both Correns and Quenot foreshadowed what was more definitely suggested by Bateson and Punnett in 1905, as the "*presence and absence hypothesis*." C. C. Hurst the next year developed this hypothesis to its logical conclusion.³

According to this hypothesis the difference, say, between two varieties of cow-peas, one of which has red and the other white seed coats, is due to the presence of an allelomorph for red in the one case and its absence in the other. When the reducing division occurs in the hybrid this allelomorph was supposed to pass entire into one of the daughter cells, thus giving two types of gametes, one with, the other without, the potentiality of producing red pigment in the seed coat. It is usually assumed that the dominant member of the character pair corresponds to the presence, and the recessive member to the absence, of an allelomorph, though there are apparent exceptions to this rule.

While some biologists still adhere to the idea that the organism may be regarded as a structure built up of parts each of which represents a separately inherited character and is represented in the germ plasm by a pangene, this idea is much less prevalent than it was a few years ago. Recently the attempt has been made to formulate a description of Mendelian phenomena in terms that do not involve any hypothesis concerning the nature and interaction of the germ plasm elements which are certainly responsible for these phenomena. Notable amongst such attempts is the "genotype-conception" of Johannsen.

³I am also indebted to Dr. Shull for these historical facts concerning the presence and absence hypothesis.

Johannsen does not define very definitely his term "gene," further than to apply it to the cell organs or cell substances, whatever they may be, that are responsible for Mendelian phenomena. He particularly insists that the gene is not to be regarded as the basis in the germ plasm of a particular character, but that Mendelian phenomena arise from differences in corresponding genes in two varieties. This idea is in close accord with that of Mendel, which we have already discussed. Johannsen's gene and Mendel's formative element appear to be the same thing. Any particular character is probably the result of the interaction of several or many genes, and any one gene may bear a relation to many characters.

In a field of investigation where so much confusion has existed as to the meaning of terms, and where widely different views have been maintained as to the significance of the phenomena observed, it is necessary, in order to render discussion fully intelligible, to describe quite accurately the facts, which are not in dispute, and thus attach definite meanings to the terms used. It is not so important that we should agree as to the proper use of terms as that we should understand clearly the actual meaning of a writer, whether he uses terms correctly or not. In order that the meaning which I attach to the term "Mendelian factor" may be made clear, I shall set forth in some detail the facts about a group of these factors with which I have been working for some years past.

In my investigations of heredity in the cowpea (*Vigna unguiculata*) the seed-coat colors found are as follows: white (or cream), red, buff, blue, brown, black and purple. In addition to the simple colors above enumerated, certain varieties have the surface more or less thickly covered with bluish purple dots (speckling). In

the New Era variety these dots are very numerous, while in the variety known as Taylor the dots are more thinly scattered, with considerable areas free from them. Certain other varieties, notably the whip-poorwill, are characterized by a peculiar mottling of the surface in which irregular areas of darker shade are separated by lighter areas, apparently of the same coloring material, but less dense. There are also two genetically distinct types of "eye," the data concerning the inheritance of which have already been published.⁴ Finally, certain varieties are characterized by irregular longitudinal stripes on the sides of the seeds. We have thus, in all, 13 pairs of Mendelian characters relating to the seed coat.

Except the purple color, the inheritance of all the above characters has been worked out quite completely. Purple was introduced into my crosses from a variety that had only a small color patch about the hilum, and was not recognized as a distinct color type until after the crosses had been made. It happened that the crosses made were not such as to bring out in full the relations of this purple color to the other Mendelian factors involved. Its inheritance will be investigated later.

Without postulating anything whatever as to the nature of the Mendelian factors involved in the development of these colors, I will first set forth some of the more important facts that have been worked out concerning which factors must be present in order that a given color may develop. Since we do not know what these factors are, and hence can not give them names based on their nature, and since we do know their behavior in inheritance and the relation of their presence and absence to the development of the colors, I shall give

them provisional names based on their behavior and their relations to color development, and then, for convenience, reduce these names to mere symbols.

In no case is there a single Mendelian factor that can by itself give rise to colored seeds. I have been able to demonstrate that red, buff and brown seeds each require at least two factors. They may require others, but if so these others have not been detected. Black requires three factors and blue three.

If all these factors were distinct, these five colors would thus require twelve separate factors for their development; but the whole number of these factors for color (omitting purple) is only six. The same factor takes part in the development of more than one color. In fact, there is one that is common to the whole series, and when this factor is absent white seeds result, even if the remaining five are all present. We may designate this factor as the general color factor, and represent it by the symbol *C*. If we represent the other five factors by the letters *R* (red), *U* (buff), *Br* (brown), *B* (blue) and *N* (noir = black), the conditions required for the production of each color in this series, as shown in the breeding experiments, is shown in the following table:

CONDITIONS REQUIRED FOR DEVELOPMENT OF COLORS

Colors	Factors Necessary	Factors Having no Effect	Factors Which Must be Absent
White		<i>R, U, Br, B, N</i>	<i>C</i>
Red	<i>C, R</i>	<i>N</i> or <i>B</i>	<i>U, Br, B</i> or <i>N</i>
Buff	<i>C, U</i>	<i>R, N</i> or <i>B</i>	<i>Br, B</i> or <i>N</i>
Brown	<i>C, Br</i>	<i>R, U, B</i>	<i>N</i>
Black	<i>C, Br, N</i>	<i>R, U, B</i>	
Blue	<i>C, N, B</i>	<i>R², U²</i>	<i>Br</i>

In this table the names of the colors are given in the first column. In the second column are given the factors that must be

⁴ *Amer. Nat.*, Vol. XLV., No. 537, September, 1911, pp. 513-24.

⁵ These do not affect blue, but are visible with blue.

present in order that a given color shall appear. Thus none of these six factors is necessary to the production of white seeds. For red seeds there must be present the factors *C* and *R*; and so on. It will be noticed that the factor *C* is necessary in all the colored types.

The third column shows the factors whose presence or absence is immaterial in each color type. Thus white seeds may or may not possess any or all the factors except *C*. Judging from results secured by others in other species, there could also be white seeds possessing the factor *C*, provided all the other factors concerned in color production were absent, but thus far I have not found white seeds of this character in cowpeas.

In the case of red and buff seeded varieties it will be noticed that *N* or *B* may be present, but they may not both be present. The reason for this is that *C*, *N*, and *B* are the factors for blue; hence if both *N* and *B* were present in red or buff varieties these would be converted into blue. Opposite blue, in the third column, *R* and *U* are given as factors that may be present without modifying the blue color; while this is true, it is also true that these colors (red and buff) can be seen along with the blue in blue seeds. This seems to be due to the fact that blue is a sap color, and is usually not very intense, while red and buff are pigments in granular form. It is interesting to note at this point that these surmises of mine as to the nature of these colors have been confirmed by Dr. Mann, to whose work with these pigments I shall refer later.

The last column shows factors that must be absent in the various color types. Thus, if *C* is present, white seeds do not occur, unless indeed all the other factors are absent as well. The factor *U* can not be present in red seeds, for it would convert

them into buff. In general, omitting blue, each of the colors named in column one completely conceals, or possibly prevents the development of, all those above it. Hence the factor *Br* can not be present in red and buff seeds. As already stated, the factors *B* and *N* can not both be present in red seeds, and the same is true of buff, though either of them may be present if the other is absent. The factor *N* must be absent in brown seeds, for otherwise we should have all the factors for black, and black renders brown invisible. Similarly, the factor *Br* may not be present in blue seeds, since it would change their color to black.

All the factors mentioned in this table are fully demonstrated in the experimental work, the full data of which will be published later. Not only that, but these factors, whatever they are, can be shuffled about and combined in any manner desired, practically at will. There are no intermediate stages to be dealt with. A factor is either present or not present, and that is the end of it. The only difficulty that presents itself in attempting to produce any color desired, lies in the indifferent factors shown in the third column of the table. In some cases it is necessary to test a variety by appropriate cross-breeding in order to ascertain what characters are concealed in it, before we know what to expect when it is crossed with certain others. This will be necessary, for instance, in order to ascertain whether a brown variety possessed the factors *R* and *U*. It would not be necessary, however, to test any variety having colored seeds in order to learn whether it contains the factor *N*, for if *N* is present the green parts of the plant will exhibit anthocyan, which they will not do if *N* is absent. To learn whether a white variety contains *N* we should cross it with brown, in which case

the hybrid would be black or brown according as the factor N is or is not present.

This factor, to which I have given the symbol N , and which is necessary to the production of both blue and black seed-coat colors, is, as already stated, one of the factors for the production of anthocyan in the green tissues, and this was one of the reasons which led me to suspect that the blue pigment is a sap color. This same factor N is also one of those necessary for color in the flowers. But its importance in the economy of the plant does not seem to stop here. It may be merely a coincidence, but amongst about 4,500 third-generation plants grown in my experimental plots last year, this factor was present in every one of them that made even a fair yield of seed, except one strain of browns, and, with this exception, in those plants which lacked this factor the yield of seed was very meager. Furthermore, it is present in every standard variety of cowpeas in this country, so far as I have observed, although many varieties have doubtless been produced that did not possess it. These facts would seem to indicate that this factor is in some way connected with vigor and vitality in the plant.

Regarding the above colors, my breeding experiments led me to think that red, buff, brown and black were pigments related to melanin, and that blue was a sap color related to anthocyan. Dr. Albert Mann has made a study of this matter and has secured interesting and important results, which he will publish later. He kindly permits me to state that these surmises of mine were correct. I mention this fact to show that breeding experiments may be helpful to the chemist in investigating the chemical nature of these pigments.

We now have before us some of the facts that so badly need interpretation. The case is not nearly so simple as this state-

ment of facts would indicate, for there are other important classes of facts that I have not considered because to do so adequately would require too much space. It is not surprising that such facts as these have led to much controversy. It is inevitable that the human mind shall attempt to comprehend what it clearly apprehends, and hence that theories of various kinds should have been proposed to explain these facts. When we consider the fact that these factors can be shuffled and recombined in every possible way, just as if they were concrete entities, each represented by an independent morphological element in the germ plasm, it was to be expected that theories should be proposed involving such elements. It is inevitable that this should have been the case. Such theories present a simple idea, easily grasped, leading to an almost absurdly simple scheme of symbols for portraying the facts of segregation and recombination.

Some of these theories have gone so far beyond the present possibilities of investigation that many biologists, especially those only slightly familiar with the facts of Mendelism, have entered vigorous protests, and have even gone so far as to try to rule the facts themselves out of court. I wish to suggest to those who have not themselves conducted Mendelian studies, that it is well not to be too dogmatic about the facts in a field of investigation with which one is not very familiar. It would be a serious matter to convince any one who has watched the shifting and recombining of these factors that they are not real things. For one not thoroughly familiar with Mendelian phenomena to question the *facts* of segregation and recombination is as unseemly and unscientific a procedure as it would be for me to question the facts of physiological chemistry. The real trouble is not with the facts. It is with the interpreta-

tion of these facts. Just at present we have more facts of a certain kind than we know what to do with. We need some one to put meaning into these facts. We are in the position of a man lost in a wilderness. What he needs to find is a road. It does not make so much difference where this road shall lead, for all roads lead into each other. If he can find any road, it will lead him to where he can find people, and these can point out other roads leading more nearly in the direction he wants to go.

In genetic investigations we need theories that will suggest lines of investigation that will be fruitful of results—that will lead, not to more facts of the kind we already have, but to new kinds of facts that will throw light on the subject from a new angle. "Theories," said Pasteur, "come into our laboratory by the bushel. When they have served their purpose, they are thrown out of the window." This has been so in the development of the science of genetics, but just at present the supply of theories is almost exhausted.

The things that need interpretation are the manner in which segregation and recombination are brought about, the nature of the things that segregate and recombine, and their relation to the processes of development. Mendelian factors, that is, those factors of development that behave in Mendelian fashion in heredity, of necessity relate only to those differences that exist between organisms that are closely enough related to cross-breed with the production of fertile progeny. In certain species crosses, and in some other cases in which there is reason to suspect either a diseased condition of the cytoplasm, or a departure from the normal behavior in gametogenesis, cases have been found in which the factors of development do not segregate and recombine in the simple manner represented by the Mendelian formulæ. Aside from

these cases, it seems a fair inference from the results thus far obtained that the differences between organisms sufficiently related to permit of cross-breeding with the production of fertile offspring which reproduce sexually in a normal manner, are universally subject to the laws of segregation and recombination. There is one quasi-exception to this statement; there are certain factors that, instead of segregating in the usual presence-absence fashion, segregate from each other, so that they can not reside permanently in the same pure-breeding line. In my cowpea investigations I have found a set of three such factors; when only one of these is concerned in a cross we get the usual phenomena of presence-absence segregation. But if any two of the three are brought together in the same zygote they segregate from each other. These three factors are the factor *Br*, above mentioned (the special factor for brown pigment in the seed coat), and the New Era and Taylor types of speckling.

The question whether the deeper and more fundamental characters of the organism, such as are concerned in the differences between organisms widely separated in the organic world, are inherited in Mendelian fashion is purely academic and of no practical importance either to the theory of heredity or the practise of the breeder, for this question can never be submitted to experiment, nor could the most definite knowledge on this point be applied in the production of new and improved races of plants and animals.

At present Mendelists are plodding along practically without working theories. Let us hope that some of them will stumble on to facts of a new kind that will give meaning to those we already have.

Personally, I am of opinion that the chemistry of the pigments is a field that is of great importance to the theory of

heredity. The facts regarding the inheritance of color are better known than is the case with other groups of characters. The suggestion that the "factors" above mentioned are merely the power of producing certain chemical substances seems to me to be worthy of consideration. I believe that on this suggestion a new working theory of inheritance can be constructed that will explain the facts without recourse to the idea of "unit-characters," "pangenes," or any kind of character "bearers," in the sense of bodies or substances which are alone responsible for the development of a given character. It would be out of place here to attempt to present such a theory. I think, however, that an illustration of what I mean may be permissible. Let us suppose that a series of wireless stations, say in San Francisco, Denver, St. Louis and Washington, attempt to relay a message from the Pacific to the Atlantic. Now, if the St. Louis station should fail to do its part, the message would not arrive. In this case, we may not say that, if this station had done its part, it would have been *the* sender of the message. The relaying at that station is merely one of a chain of events that are necessary to the success of the experiment. But if St. Louis fails, then that station is responsible for the *failure* of the message to arrive at Washington.

The production of red pigment in the seed coat of the cowpea may possibly be a complex process in which every part of the living substance of the cell is concerned; but if a single cell organ which performs a necessary part of this process fails to play its part, then red pigment fails to develop. The cell organ whose failure to perform a usual function may thus be accountable for the lack of pigment formation might then be considered the "gene," as Johannsen calls it, for the

absence of red pigment; while the whole organism might be the gene for the presence of this pigment.

In order that the study of the physiological chemistry of pigment formation shall give results of the greatest importance to the theory of heredity, it would be an ideal condition if such work could be carried out by one who possesses a wide acquaintance with the facts and theories in both these sciences. But such men are not plentiful. The next best scheme would be a cooperative study of the subject by two men, one in each field. I am happy to be able to say that Dr. Bartlett has consented to take up the chemical end of this work in connection with my investigations of the genetic phases of the problem, and Professor Piper has promised to grow the material for such study. Gortner's important work in this field, in connection with Dr. C. B. Davenport's work on genetics, has already been mentioned. With all these investigations, and those of Miss Wheldale and Professor Bateson at Cambridge, it is to be hoped that we shall gain a somewhat more definite view of the nature of Mendelian factors.

W. J. SPILLMAN

THE PERUVIAN EXPEDITION OF 1912

THE Peruvian Expedition of 1912, organized under the auspices of Yale University and the National Geographic Society for the purpose of carrying on geographic and anthropologic exploration in Peru, will endeavor to continue and extend the work of the Yale Peruvian Expedition of 1911, utilizing the discoveries made then and continuing further along the same lines.

It is our purpose to pursue intensive studies in the region where reconnaissance work was done on the last expedition, taking advantage of the discoveries then made to guide the plans for this year.

The work planned for the expedition is as follows:

I. In topography:

1. To make a topographical map on a scale of 2 miles to the inch, with a contour interval of 100 feet, of the Cuzco basin.
2. To connect that part of the Vilcabamba survey made by the topographer of the 1911 expedition with his trans-Andean cross section from Abancay to Camaná.
3. To make a map of the so-called Vilcabamba country which lies north of Cuzco between and including the valleys of the Apurimac and Urubamba rivers. Some portions of this were finished by Mr. Kai Hendriksen, topographer of the 1911 expedition, but owing to the difficulties of the route he was only able to make a beginning.

Every effort will be made to complete the map of Vilcabamba, placing on it not only the ancient and modern sites, but also the data for further physiographical and geological study.

4. To map the routes connecting the later Inca capital of Vitcos with the rest of Peru.
5. To discover and identify the places mentioned in the Spanish chronicles and in the early accounts of Peru, particularly the places connected with the 35 years of Inca rule after the advent of Pizarro. As many of these place names have changed, it will be necessary to identify the places by a careful comparison of their situation and surroundings with the itineraries and descriptions given in the chronicles.

II. In geology:

1. To make a careful survey of the Cuzco basin and its vicinity, with special reference to the age of gravel deposits where human and other remains were found on the expedition of 1911.
2. To make a geological reconnaissance of the Vilcabamba country, continuing the work already begun.

III. In meteorology:

1. To establish and equip meteorological

stations at Cuzco and at Santa Ana, stations at which continuous observations may be made for several years, these observations to be supplemented by field observations taken by various members of the expedition wherever practicable.

IV. In pathology:

1. To study the various diseases throughout the region visited, and their geographical extent.
2. To study the effect of coca chewing.

V. In osteology:

1. To study the bone deposits in the Aya-huayeco quebrada where human and other bones were found on the 1911 expedition.
2. To collect osteological material not only in the Cuzco gravels, but also in the mountains of Vilcabamba.

VI. In forestry:

To make a reconnaissance survey of the Vilcabamba region between the Apurimac and the Urubamba valleys.

VII. In anthropology:

1. To take photographs and physical measurements of native types throughout the region visited, with particular reference to a study of the distribution of the more important groups.
2. To collect material for a study of the distribution of types of cranial deformation.

VIII. In archeology:

1. To make a thorough investigation of the region round about and north from Cuzco and Pisac, photographing, measuring and describing whatever architectural material presents itself.
2. To continue the investigation of the ruins discovered on the expedition of 1911.
3. To penetrate still further into the jungles of the Pampaconas Valley and beyond, to see whether any more remains of Inca occupation can be found.

The expedition will include a geologist, an osteologist, a surgeon, three topographers and three assistants, besides the director. The geologist will be Professor Herbert Gregory, Silliman professor of geology in Yale University, and the osteologist, Dr. George F. Eaton,

curator of osteology in the Peabody Museum of Yale University.

HIRAM BINGHAM,
Director of the Expedition

**SAMUEL BUTLER AND BIOLOGICAL
MEMORY**

THE present vogue of the books of Samuel Butler—not a great vogue but one fairly commensurate, perhaps, with the scientific worth and general interest of his writings—has led me to a rather critical reading of the four books and several scattered essays of this partly scientific, partly artistic, mostly iconoclastic, and wholly clever and epigrammatic modern namesake of the greater Samuel Butler of two centuries gone.

He finds himself dubbed in the British Museum Library catalogue as "philosophical writer," being alphabetically bestowed between "Samuel Butler, bishop" and "Samuel Butler, poet"; and in one of his essays tells a pretty story to account for his title.

The library catalogue is, as many will recall, printed and pasted in huge tomes, hundreds of them, and changes in its arrangement are not easily made. When our Butler found himself beginning to get into the catalogue he found also that he was getting mixed up with his namesake bishop and his namesake poet, and as yet he had no distinguishing title of his own. When he complained to the Library directors of his trouble it was pointed out to him that it was largely his own fault in not having sufficient distinction or distinctiveness to be classified properly. He must have a title. What was he, really? His writings were partly about Italian art, partly about the authorship of the *Odyssey*, partly about evolution and partly of the nature of stories. How was he to be distinguished? Had he any title? He replied, after meditation, that he was a Bachelor of Arts. The director pointed out that as far as his book titles were not actually confused with those of the bishop and poet, they were pasted in between theirs, and that if he were catalogued as "Samuel Butler, B.A.," the strictly alphabetical sequence of the catalogue

would be wronged. Could he not, perhaps, arrange to be a Master of Arts? Butler replied that he understood that Cambridge stood one a Master for five guineas, but he was not willing to go above three guineas ten! Well, anyway, was the answer, he must be "Samuel Butler, something, between *bi* and *po*!" So it was finally agreed that he should be "Samuel Butler, philosophical writer"—*phi* agreeing properly with the order in which he had already been irrevocably pasted!

Now this long digression, by way of introduction, from the subject of my letter, has after all a definite significance in relation to it. It has indeed, for me, at least, a double significance. It suggests something about British ways and something about the doubt as to how Samuel Butler's writings, even the four books about Darwinism, Lamarckism and biological memory, should be classified. Are they contributions to science, or to pure literature? Certainly, they are contributions to the gaiety of nations when they are not, as occasionally they are certainly are, contributions to that which makes the judicious to grieve. Whatever of sharpness in polemic one may tolerate in a critic of Darwinism, innuendo and really almost scurrilous personal attack on Charles Darwin one will not tolerate. And Butler comes to no less than this in his attempt to show Darwin's bad faith in a matter of the use of a certain freely modified translation of an account of Erasmus Darwin by Krause, in *Kosmos*.

Butler, though strongly anti-Darwinian (that is, anti-natural selection and anti-Charles Darwin) is not anti-evolutionist. He professes, indeed, to be very much of an evolutionist, and in particular one who has taken it upon his shoulders to reinstate Buffon and Erasmus Darwin, and, as a follower of these two, Lamarck, in their rightful place as the most believable explainers of the factors and method of evolution. His evolution belief is a sort of Butlerized Lamarckism, tracing back originally to Buffon and Erasmus Darwin. He is equally insistent on degrading the explanations of Charles Darwin, Wallace and Weismann, viz., the selection

champions, to their rightfully ignoble place of puerility and imbecility. And finally he is intent on reestablishing the factor of design in evolution. He holds strongly to a certain sort of teleology in organic change. Organisms make themselves what they are somewhat understandingly, as it were. They know what is good for them, and try to do it and be it.

Granted, now, that this man is a master of epigram, paradox, sophistication, argument and audacity, and of a literary style as animated and sparkling as it is bold, and you can fancy that his books make interesting reading to professed students of evolution and to scientific men—at whom he sneers and laughs—as well as to those readers “whose time is worth money,” whom he exalts and to whom he explicitly directs his writing.

The four books of this sort that were written originally some thirty years ago and that have been recently re-issued by Fifield in London and—I believe—Putnams in New York are: “Life and Habit” (1878), “Evolution, Old and New” (1879), “Unconscious Memory” (1880) and “Luck or Cunning” (1881). In 1890, in *The Universal Review* (London), he published three essays (really one in three parts) under the title “The Deadlock of Darwinism,” in which he reiterates the general conclusions and theories set out in detail in his earlier writing.

In addition to these four books, offered as direct contributions to evolution discussion, a much earlier book, called “Erewhon” (= Nowhere) (1872), contains in its pages of fantastic picturing and imagination the budding thoughts that later form the basis of his anti-Darwinism. Particularly in the chapter called “The Book of the Machines” are his ideas of design and his denial of chance in world evolution set out. This book has had a wide diffusion, and is the one which really gave him literary repute. It is a picturesque account of the life and philosophy of the non-existent Erewhonians, and its pages reveal the imagination of a Wells and the satire of a Bernard Shaw. Shaw, indeed, has strongly commended it, and Augustine

Birrell has called it the best satire since “Gulliver’s Travels.”

And I have not yet got to a word about “biological memory.” Well, it will take but few sentences to point out Butler’s relation to this subject. The fact that he used “Unconscious Memory” as title for one of his books shows the store he set by his notions about biological memory—notions that he undoubtedly developed independently, and that he believed, at the time he formulated them, to be wholly original with him. Butler’s theory that heredity and instincts are the results of, or are themselves, biological memory, was set out in detail in his first biological book, “Life and Habit” (1878). The book “Unconscious Memory” (1880) is chiefly devoted to recording his discovery that he had been antedated by Ewald Hering, whose address on “Das Gedächtniss als allgemeine Funktion der organisirter Substanz,” given before a meeting of the Vienna Imperial Academy of Sciences on May 30, 1870, he translates and prints in full. The book also contains a long translation from von Hartmann, and some discussion of it, to show that Hering’s and Butler’s theory of biological memory is not at all von Hartmann’s unconscious control. And it is in this book, too, that Butler (Chap. IV.) says his worst about Darwin.

As a matter of fact, Hering was not the first to have the conception of an explanation of repetitive phenomena in organisms on the basis of cell or molecule memory. Lamarck and Haeckel had both suggested such an idea. In our own country, Cope and Hyatt, not earlier, but undoubtedly each originally, expressed the essence of such a conception. Hyatt indeed coined the word “mnemogenesis” for use in connection with his ideas about heredity and instinct. But Hering was certainly the first to give the conception full form, to compose it of details, and to suggest a physical basis for it, viz., the reception and storing by the body protoplasm of vibrations coming from without, so that this protoplasm became actually changed in capacity by its

various, and especially by its repeated, experiences.

Then came Butler, and, without knowledge of Hering's ideas, and out of a conviction that Darwin's natural selection of fortuitous variations was an absurd explanation of such fit things as instincts and hereditary repetitions, and that Lamarck's explanation of modification of individuals by effort and intent, carried over into racial acquirements by heredity, was a much better one but needed something else to make it complete, he re-invented the conception of biological memory and worked it out to its logical extreme. Just what this extreme is, and what the details of Butler's theory are, I leave to any of my readers interested to find out from Butler's books. For besides the interesting speculations of an intelligent and imaginative man about a subject that has, I am convinced, some real things in it to be found out some day, they will get from their perusal a gentle titillation of shock and amusement, such as the day's duty of "scientific reading" rarely brings.

Since Hering and Butler, have come, of course, Richard Semon with "Die Mneme" and its new, and perhaps useful, terminology for the older ideas, and lastly the blessing of Sir Francis Darwin on the whole idea, as well as on Butler himself, bestowed in his British Association President's address of 1908. But as it is Butler more than biological memory that this letter is meant to call attention to I may stop here. Butler died in 1902, and is only now coming to his hearing.

VERNON L. KELLOGG

LONDON,
February 24

THE DEATH OF NETTIE MARIA STEVENS

At a meeting of the faculty of Bryn Mawr College, held May 6, 1912, it was voted to make the following record in the minutes:

WHEREAS, the faculty of Bryn Mawr College has heard with sincere sorrow of the death of Nettie Maria Stevens, A.B. and A.M. of Leland Stanford Junior University, graduate scholar in biology in Bryn Mawr College 1900-01, president's European fellow 1901-02, resident fellow in biol-

ogy 1902-03, doctor of philosophy of this college in 1903, sometime research fellow in biology, Carnegie research assistant and Alice Freeman Palmer research fellow, and since 1904 as reader and then as associate in experimental morphology, a member of the teaching staff and of the faculty,

Resolved, that we, the faculty of Bryn Mawr College, desire to record our appreciation of her talent for research, of the skill and assiduity with which she carried on difficult investigations, achieving a success that placed her in the very front rank of students of science and gave her a world-wide reputation among workers in biology. No less would we recognize the faithfulness with which as a member of the faculty she responded to every call for her services in teaching or in any general work of the college. We deplore her loss. We honor her memory.

Resolved, that copies of these resolutions be sent to the relatives of Dr. Stevens, to the board of directors and to SCIENCE.

SCIENTIFIC NOTES AND NEWS

At the suggestion of the German emperor, the Berlin Institute for Infectious Diseases will be named in honor of Robert Koch.

THE faculty, students and alumni of the university of California will erect in the museum corridor of the new agricultural hall of the University of California a bronze bust in honor of Dr. Eugene W. Hilgard, emeritus professor of agriculture.

PROFESSOR GRASSET, on the occasion of the thirtieth anniversary of his professorship of medicine at Montpellier, was presented with his bust and a medal.

PHYSICIANS of Philadelphia have been invited to join in honoring the memory of Dr. John Herr Musser by subscribing to the memorial fund to be used to endow the social service department of the University Hospital, Philadelphia, of which he was the founder and president. The will of Dr. Musser provides that if the personal estate reaches \$240,000, the sum of \$15,000 shall be given to the University of Pennsylvania for the endowment of a fellowship in honor of the late Dr. Robert M. Girvin.

THE new medical laboratories for the two years' course in medicine given at the Univer-

sity of North Carolina were opened on May 8. These laboratories present a complete equipment for anatomy, physiology, pathology, histology, pharmacology and the other studies usually included in the first two years' course. Provost Edgar F. Smith, of the University of Pennsylvania, delivered the chief address. The honorary degree of LL.D. was conferred upon Provost Smith, Dr. Charles W. Stiles, in charge of the work of the Rockefeller Hookworm Commission, and Dr. Richard H. Lewis, formerly secretary of the North Carolina Board of Health and president of the National Health Association.

DR. W. P. BRADLEY, professor of chemistry at Wesleyan University, has been granted leave of absence for the year 1912-13, to organize a department of research for the United States Rubber Goods Company.

THE American Philosophical Society has appointed the following delegates to represent it on the occasions designated: The Hon. Charlemagne Tower, at the inauguration of John Grier Hibben as president of Princeton University, on May 11; Dr. Morris Jastrow, Jr., at the fourth Congress on the History of Religions, to meet in Leyden on September 9-13 next; Professor Edward W. Morley, of West Hartford, Conn.; Professor Marston T. Bogert, of New York, and Professor Theo. William Richards, of Cambridge, at the eighth International Congress of Applied Chemistry, to be held in Washington and New York, September 4-13 next.

DR. FRANZ BOAS, professor of anthropology in Columbia University and in the University of Mexico, has returned to New York after a winter in Mexico and has immediately sailed for England to attend the Congress of Americanists to be held in London beginning on May 27.

DR. GEORGE BYRON GORDON, director of the University of Pennsylvania Museum, has been appointed a delegate to represent the university at the Eighteenth International Congress of Americanists.

PROFESSOR GEORGE H. PARKER, Harvard University, gave the sixth lecture in the

course offered to the students in the department of biology at Trinity College, on the evening of May 2 with the subject, "The Nervous System."

MR. TALCOTT WILLIAMS, director of the School of Journalism of Columbia University, is giving the Phi Beta Kappa address at the universities of Wisconsin, Minnesota and Nebraska on May 6 to 9 on "The Old Learning and the New."

PROFESSOR JOSEPH JASTROW, of the University of Wisconsin, will give the commencement address at the Normal School, Emporia, Kansas, on June 5, and also addresses at the opening of the summer school there.

PROFESSOR LILLIEN J. MARTIN, of the psychological department of Stanford University, gave an address on "Ueber die Localisation optischer Vorstellungsbilder" at the Fifth Congress for Experimental Psychology, held in Berlin from April 16 to 19, 1912. Her address appears in full in the April number of the *Monatschrift für Psychiatrie und Neurologie*.

SPECIAL lectures will be given at Kings College, University of London, by Dr. F. W. Mott, F.R.S., on May 20, 27, June 3 and 10, on "Heredity considered from the Point of View of Physiology and Pathology."

THERE will be civil service examinations on June 5, for the position of agricultural propagator in the Philippine Service at a salary of \$1,600; for examiners of surveys in the field service of the Department of Agriculture, at entrance salaries ranging from \$1,200 to \$1,500, and for scientific assistants, qualified in farm equipment, in the Bureau of Plant Industry, at salaries of \$1,200 to \$1,400.

THE late Henry Iden bequeathed \$100,000 to Cooper Union, New York City, and among other public bequests \$10,000 each to the American Museum of Natural History, the New York Botanical Garden and the New York Zoological Society.

Two eggs of the Great Auk, as we learn from the *London Times*, were sold on April 17 at Mr. J. C. Stevens's rooms in King-

street, Covent Garden, the property of Lady Smyth, of Ashton Court, Somerset, who inherited them from the late Sir J. H. Greville Smyth. The finer of the two was purchased at an auction in Kent, and resold at Stevens's on April 24, 1894, for 180 guineas; it now brought 150 guineas. The second egg, which went for 140 guineas, was purchased with a number of sea-birds' eggs, many years ago, by the late owner, but nothing appears to be known of its earlier history. Both were bought by Mr. Ward. Sir J. H. Greville Smyth had another specimen of the egg (which was sold at Stevens's in 1888 for £225). This was presented by Lady Greville Smyth to the Bristol Museum. A "census" by Mr. Edward Bidwell, in connection with the Great Auk, shows that there are in existence and recorded 80 skins and 73 eggs.

THE Austrian government has purchased for about \$600,000 the only two radium mines at Joachimsthal which were owned by private individuals. It is estimated that the two mines will yield annually about 3 grams of radium. Plans are under way for the development of Joachimsthal as a resort for the treatment of disease by radium.

A GIFT of \$50,000 has been made by a donor who desires his name withheld for the purpose of furthering the work of the National Committee for Mental Hygiene. The same individual has agreed to give \$50,000 more, on condition that the sum of \$200,000 additional be secured. The *Journal* of the American Medical Association states that the purpose for which the committee was formed is the study of all matters connected with the commitment, care and after-treatment of the insane. Plans for the study of this subject have been carefully prepared, and it is intended to encourage the formation in the various states of allied but independent societies with similar aims to those of the national committee. A special subcommittee, of which Dr. William L. Russell, superintendent of the Bloomingdale Hospital, is chairman, has been formed to begin the work outlined, and an office has been opened in the

Germania Life Building, New York City. Dr. Thomas W. Salmon, of the United States Public Health and Marine-Hospital Service, has been granted leave of absence by the government to undertake this work and has been engaged to conduct the studies outlined by the committee. The newly elected officers are: president, Dr. Llewellys F. Barker, of Johns Hopkins University; vice-presidents, Dr. William H. Welch, of Johns Hopkins Medical School; Dr. Charles P. Bancroft, superintendent of the New Hampshire State Hospital, Concord, N. H.; treasurer, Otto T. Bannard, president of the New York Trust Company; chairman of the executive committee, Dr. George Blumer, dean of Yale Medical School; chairman of the finance committee, Professor Russell H. Chittenden, director of Sheffield Scientific School of Yale University; secretary, Clifford W. Beers, organizer of the National Committee for Mental Hygiene.

UNIVERSITY AND EDUCATIONAL NEWS

By the will of Charles Herbert Pratt, the Massachusetts Institute of Technology receives a large bequest to endow a Pratt school of naval architecture and marine engineering. The income of the estate is to accumulate until the sum of \$750,000 has been reached, though it may be used at the expiration of twenty-one years.

GOVERNOR FOSS has signed the bill passed by the Massachusetts legislature appropriating \$50,000 annually for five years to the Worcester Polytechnic Institute. The grant is to be extended for an additional five years if in the meantime the institute obtains \$350,000.

AN anonymous benefactor has given \$100,000 to Hamilton College for the erection of a new library building.

COLUMBIA UNIVERSITY has received from Mr. and Mrs. William R. Peters a gift of \$50,000 to establish a fund for engineering research in memory of their son William R. Peters, Jr.

A SECOND gift of \$25,000 to Brown University from Mr. John D. Rockefeller, Jr., is

announced. The endowment has now reached \$815,000 toward the desired million dollars.

APPROPRIATION bills for the College of Agriculture, Cornell University, to the amount of \$907,000, of which \$788,000 is immediately available, were passed by the New York legislature at its recent session and signed by Governor Dix. The Veterinary College received an appropriation of \$105,000, bringing the total up to \$1,012,000. Of the appropriation \$329,000 is for the erection of new buildings for the use of the departments of forestry, agronomy and animal husbandry; \$129,000 of this amount is not immediately available. There was reappropriated \$182,000 for the completion of work already under way; \$265,000 for the current expenses of the college, and \$141,000 in what is known as the supply bill.

THE Johns Hopkins School of Technology will be opened next fall, offering instruction in three branches, mechanical and electrical engineering and applied chemistry. A committee headed by Mr. R. Brent Keyser, president of the board of trustees, Dr. J. S. Ames, director of the physical laboratory, and Dr. William B. Clark, professor of geology, has made a trip to the educational centers of the north, where they consulted with a number of educators on plans for organizing the institution.

DR. JOHN GRIER HIBBEN, hitherto Stuart professor of logic, was installed as president of Princeton University on May 11. There were present President Taft, Chief Justice White and delegates from one hundred and seventy-one educational institutions. The oath of office was administered by Justice Pitney, and President Hibben made an inaugural address on the essentials of a liberal education. Degrees were conferred on President Taft and Chief Justice White. At the luncheon speeches were made by them and by ex-President Patton, of Princeton; President Lowell, of Harvard; President Hadley, of Yale; President Butler, of Columbia, and President Schurman, of Cornell.

DR. DAVID L. EDSALL has been elected to the Jackson professorship of clinical medicine in

the Harvard Medical School to fill the vacancy made by the resignation of Dr. Frederick C. Shattuck, under the retiring rules of the Massachusetts General Hospital. At the same time Dr. Edsall has been appointed to one of the two permanent medical services at that hospital. He is a graduate of Princeton and of the University of Pennsylvania Medical School. He was professor in that school until 1910, and since in the Medical School of Washington University, St. Louis.

THE trustees of Cornell University have made appointments and promotions as follows: C. G. Woodbury, professor of pomology; Hugh Charles Troy, professor of dairy industry. The following assistant professors were promoted to the rank of professor: J. A. Bizzell, in soil technology; W. A. Riley, in entomology; G. W. Herrick, in entomology; H. W. Riley, in farm mechanics, and H. E. Ross, in dairy industry. The following instructors were promoted to the rank of assistant professor: L. J. Cross, in agricultural chemistry; Robert Matheson, in entomology; George C. Embury, in entomology; Arthur L. Thompson, in farm management, and Ralph H. Wheeler, in extension teaching. Albert Edward Wells, superintendent of shops of Sibley College, was appointed assistant professor of machine design.

JOHN HARLAND KELSON, head of the department of applied mechanics at Case School of Applied Science, Cleveland, Ohio, has been elected professor of applied mechanics at the Worcester Polytechnic Institute, succeeding the late Professor E. B. Hancock.

THERE have been appointed in the School of Journalism of Columbia University, Dr. E. E. Slossen, of the editorial staff of *The Independent*, formerly professor of chemistry in the University of Wyoming, as associate, and Dr. Walter B. Pitkin, of the department of philosophy of the university, as associate professor.

At the University of Wisconsin, Dr. James B. Overton has been promoted from assistant professor of botany to associate professor of plant physiology, and Mr. Gilbert M. Smith

from assistant in botany to instructor in botany.

MR. E. N. ZERN, professor of coal mining at the University of Pittsburgh, has been recently appointed professor of mining engineering at the West Virginia University. Mr. George Grow has also been made assistant in the College of Engineering at the same institution.

HENRY LEIGHTON, formerly instructor in the school of mines, University of Pittsburgh, has been advanced to be assistant professor of economic geology, in charge of the department of economic geology and ceramics.

MR. J. W. COBB, B.Sc., has been appointed to succeed Dr. Bone, F.R.S., as Livesey professor of coal gas and fuel industries at Leeds University.

DISCUSSION AND CORRESPONDENCE

THE OCCURRENCE OF STIBNITE AT STEAMBOAT SPRINGS, NEVADA

STEAMBOAT SPRINGS, Nevada, has been often cited as an example of a metalliferous deposit in the process of formation. Becker¹ demonstrated the presence of metallic sulphides in the waters flowing from the springs and described their occurrence in an amorphous condition in the spring deposits. He was unable, however, to find any of the sulphide minerals crystallized. Some years later Lindgren² announced the discovery of minute crystals of pyrite and stibnite in sand and gravel that had been brought up from the bottom of a prospect shaft penetrating the sinter. It was evident from the mode of crystallization of these minerals that they had been deposited from the heated waters of the springs.

During a recent visit to the springs a grayish mud was noted in the bottom of several pools at the northern end of the sinter terrace, about a half mile from the station. On examination under a microscope it was seen that minute acicular crystals of stibnite made up a large proportion of the mud. These were

usually very thin and, when perfect, shaped like the blade of a Roman sword with parallel edges and blunt point. The crystals were too minute for accurate measurement, but the forms observed were probably the brachy- and macro-pinacoids and a macrodome. The larger crystals were frequently split towards one end into a narrow fan of finer blades and many individual crystals were bent and curved. Usually the stibnite was segregated in felted balls and occasionally completely surrounded microscopic grains of sand, which had served as nuclei for the forming crystals.

The remainder of the mud was made up of diatom skeletons, fragments of chalcedonic quartz, kaolinized feldspar, and occasional flakes of mica and hornblende.

The water in the pools is very clear and limpid, with the exception of one unusually active spring where the suspended sediment is sufficient to make the water turbid. The temperature of the water in the pools in which stibnite was found ranged from 86° C. to 93° C., and averaged somewhat higher than that of the pools at the southern end of the terrace where the antimony sulphide is deposited as an amorphous precipitate.

Clark³ cites the experiments of Doelter showing that stibnite is soluble in water heated to 80° C., especially in the presence of sodium sulphide. Melville's⁴ analyses of the water of Steamboat Springs show sodium sulphide to be present. As the temperature of the springs in which stibnite was found is above that in Doelter's experiments, it is probable that the crystallization of the stibnite takes place as the heated waters approach the surface.

The complete envelopment of sand grains by the stibnite crystals presupposes free suspension in the water during the period of crystallization. The rounded form of the balls of felted crystals suggests that they formed under similar conditions. It is not unlikely that the stibnite crystallizes in the

pool and is kept in suspension by the constant agitation of the rising water.

The formation of one of the minerals associated with ore deposits under conditions that may be observed is of more than passing interest and a closer study is in progress.

J. CLAUDE JONES

MACKAY SCHOOL OF MINES,
RENO, NEVADA

CERIUM

IF any mineral collection contains specimens of cerium ochre or yttracrite from Bolton or any other Massachusetts locality, I should be obliged to the curator of such collection if he would inform me of the fact and give me briefly the history and description of the specimen.

B. K. EMERSON

AMHERST, MASS.

POPULARIZING SCIENCES

THIRTY years ago the incorporated city of San Diego, California, possessed a population of perhaps two thousand. Clergymen, lawyers, teachers, business men, working men, were alike members of the Society of Natural History, and its president, a physician, kept up the interest in the monthly meetings. Everybody came, bringing a rock or a shell or a bird or some object curious or rare, contributing to the little museum, and arousing discussion.

To-day a six-story concrete building is being erected on a lot given to the society for a home, one floor to be used for its museum and library, the other floors forming part of a hotel. With a present population of near 50,000, annual meetings are held by the society, which are generally attended by barely enough members for the election of officers. The library and museum are at a standstill. The meteorological records, begun by the society's president, are continued by a fully equipped station of the weather bureau of the U. S. Department of Agriculture—of which we sometimes hear boastful but seldom instructive remarks.

A marine biological station has been estab-

lished, under control of the state university, and given \$50,000 for a building—but the public rarely hears of any results, except of the occasional visit of some noted scientist, as heralded in the dailies.

A floral society now exists, and a botanical garden is proposed, to which nurserymen will sometime be invited to contribute from their commercial stock, but no strictly botanical work is in progress in the community, and the only attempt in fifteen years met with failure for lack of appreciation.

The city contains three private collections of shells, one of insects, one of birds, one or two of minerals, two botanists without herbaria, one meteorologist (in government employ), and a few others interested inactively in some phase of science, or about one naturalist to each five thousand people, which I have seen stated to be about the average number in the United States.

I recently visited one of the nearby grand ocean beaches, where the sea still breaks in spray over the rocks, as it did thirty years ago—but the pools that formerly concealed a wealth of beautiful wonders in animal and plant life have been scraped clean of their former treasures. Now and then a crab scuttles to safety. A hook and line sometimes brings one of the finny tribe from the deep—but boys and girls can hunt in vain for the many nature treasures that formerly lined the shores of ocean and nearby bay.

Children may still reap a treasure in wild flowers in springtime—by taking generous car rides and then walking—but they will look in vain in our paved streets for the trap-door spider's nest that I formerly watched, or for the miniature plants like the lichens that formerly freely decorated barren spots of earth.

With the increased cost of living, with leaps and bounds in the growth of our commercial life, with a corner lot that cost \$5,000 ten years ago now yielding an annual rental of \$6,000 to its purchaser, can you expect to find nature study gaining ground!

Science as a study is becoming too complicated for a layman to take part in the active

fashion of former times, and it is becoming yearly more expensive and difficult for one in private life to keep abreast of the times even by specializing in a restricted field.

And opportunities for one to do good scientific work with any chance of earning expense money are exceeding rare—unless a salaried position is secured in advance.

The increased number of scientific and educational institutions apparently fail to give equal facilities with the past to the independent youthful student. And the increase in volume of literature renders it impossible for any one not connected with some wealthy institution, or with large private means, to keep posted on proposed changes in nomenclature—to say nothing of the new discoveries being made.

There is no decrease in the interest of the general public in scientific work, but the existing state of affairs is probably due chiefly to expansion and greatly increased activity, resulting in a mass of unassimilated data and museums bursting beyond the bounds set by their founders.

C. R. ORCUTT

SCIENTIFIC BOOKS

A Cyclopaedia of American Medical Biography, Comprising the Lives of Eminent Deceased Physicians and Surgeons from 1610 to 1910. By HOWARD A. KELLY, M.D. Illustrated with Portraits. Two Volumes. Philadelphia and London, W. B. Saunders Company. 1912.

This work, handsome in typography and execution, and containing over twelve hundred biographies of prominent deceased American physicians, written, for the most part, in clean-cut style by various competent hands, marks a distinct advance upon any of its predecessors in the same kind. Of the earlier dictionaries of American medical biography, those of Thacher (1828) and of the eminent surgeon S. D. Gross (1861) have a definite historic value, but the separate lives are usually too long, Thacher's, in particular, being surcharged with that florid, stilted spirit which, as Dr. Holmes wittily said,

"has chewed the juice out of all the superlatives in the language in Fourth of July orations"; while the generous-minded Gross, incapable of saying anything unkind about his colleagues, was perhaps lacking in a right critical sense for that very reason. On the other hand, the later works—those of Atkinson (1878), Stone (1894) and Watson (1896)—abound in shorter biographies, but are, in the main, only directories of contemporary names. Dr. Kelly's Cyclopaedia strikes a happy balance between the extremes of florid encomium and mediocre choice, consisting, in the main, of compact sketches of the lives of medical men who have "done things," and is thus a genuine contribution to medical history. Some of these worthies have described new diseases, have introduced new drugs, new operations or therapeutic procedures, or have otherwise contributed to the elevation of American medicine as chemists, botanists, zoologists, bibliophiles, military and naval surgeons or leaders in hygienic and social movements. The editor's plan in getting up this work was two-fold: one group of his co-workers took up the physicians who were of local importance as practitioners; the other group took care of those who are of scientific importance in relation to the specialties which they helped to advance. Some of the former class might seem at first sight of little consequence, yet it will appear that as teachers, organizers of schools and hospitals, pioneers in hygiene, whether in Canada, Mississippi or the far west, they have their place in the development of earlier American medicine, even though unknown in Berlin, St. Petersburg or Vienna. Professor Horatio C. Wood, the well-known therapist, relates that he was once asked by an eminent European authority for a list of the professors of his specialty in America. Upon receiving some forty or fifty names, the astounded savant replied: "In God's name who are these people? I never heard of more than one or two of them." Identical sensations are experienced in looking over the pages of Hirsch's "Biographisches Lexikon der Aerzte," that monument of

¹ *Therap. Gaz.*, Detroit, 1911, XXXV., 92.

German industry, especially when we come to the Meyers, Müllers, Schmidts and Schmitts. In other words, many able physicians are of that exclusively local importance so well described in Sainte Beuve's famous reply to Matthew Arnold: "He was important to us."

The introduction to this Cyclopedia consists of a series of valuable historical sketches on the development of different branches of medical science in America, notably those of Dr. Charles R. Bardeen on anatomy, Dr. Martin B. Tinker on surgery, and the histories of gynecology and obstetrics by Dr. Kelly himself. Few specialists seem to know or care so little about the history of their subject as gynecologists, probably because its development has been mainly technical and instrumental. In this regard, Dr. Kelly's sketch may be pronounced the best history of American gynecology that has yet appeared. It is memorable that operative gynecology, which had no existence as a specialty before the nineteenth century, is largely of American origin—in the first instance, an expedient to repair the sequels of backwoods obstetrics, and that its principal founders—McDowell, Marion Sims, Battey, Nott, Emmet, Bozeman, Gaillard Thomas—have been natives of the southern states.

Of especial historical interest are the notices of the colonial pamphleteers on smallpox and vaccination, the eighteenth century leaders (Rush, Morgan, Shippen, Physick), the pioneers in the surgery of the vascular system and the joints, the discoverers and exploiters of surgical anesthesia, the medical botanists, the medical jurisconsults, the important physicians of the Philadelphia group, and such later worthies as William Pepper, Walter Reed, Nicholas Senn or Elizabeth Blackwell. A biography of Hezekiah Beardsley, who, in 1788, described congenital hypertrophic stenosis of the pylorus, appears for the first time. There have been some omissions, perhaps unavoidable in works of this kind, in particular, Bowditch the physiologist, Bigelow the surgeon and the clinicians James Jackson and John K. Mitchell. Of John C. Otto, of Philadelphia, who, in 1803, first described

hemophilia,¹ perhaps "*Non dat quod non habet.*" It is doubtful if Ricord and Brown Séquard can properly be included among Americans, since both were of French origin and all their life-work was identified with French medicine. On similar grounds, the omission of William Charles Wells, of South Carolina, memorable to physicists for his "Essay on Dew," seems not improper. A few points in priority in Dr. Tinker's surgical introduction may be noted. It is frequently asserted that Dr. Dixie Crosby, of New Hampshire, was the first to perform the inter-scapular-thoracic amputation (excision of arm, scapula and clavicle) in 1836. It had already been performed by Ralph Cuming, an English naval surgeon, in 1808.² Dupuytren cured a popliteal aneurism by compression in 1818,³ long before Jonathan Knight (1845) or O'Bryen Bellingham (1847), although Knight is undoubtedly entitled to the credit of doing this by digital compression. If Dr. Heine Marks really sutured a wounded heart before Farina and the Italian surgeons, it remains for him to prove it, as he mentions not a stitch of it in his published paper.

These volumes are embellished with many interesting portraits, those of Asa Gray, Fordyce Barker, Dewees, Agnew, Senn and Leidy being particularly good, while those of John Morgan, Physick, Horner (of Horner's muscle), Caspar Wistar, J. P. Mettauer and Willard Parker are probably copied for the first time. Many of the biographies have preserved traits of eccentricity in medical men who happened to be oddish, more especially those from the piquant pen of Miss Davina Waterson. The following sentences of Joseph Leidy on introducing himself before a lecture are an example of the utter freedom from swagger and snobbery which distinguishes the true man of science:

My name is Joseph Leidy, doctor of medicine. I was born in this city the ninth of September, 1823, and have lived here ever since. My father

¹ *Med. Repository*, New York, 1803, VI., 1-4.

² *Lond. M. Gaz.*, 1829-30, V., 273.

³ *Bull. Fac. de méd. de Par.*, 1818, VI., 242.

⁴ *Med. Fortnightly*, St. Louis, 1893, III., 44-46.

was Philip Leidy, the latter, on 3rd street above Vine; my mother, Katherine Mellick, but she died a few months after my birth, and my father married her sister Cristina, who was all in all to me, the one to whom I owe all that I am. At an early age I took great delight in natural history, of which I have reason to think I know a little, and a little of that little I propose to teach you to-night.

One does not need to glance at the splendid head on the opposite page to realize that this great naturalist, whose "Rhizopods of North America" is one of our finest biological classics, was *echt*, in the exquisite Emersonian sense of living "from a great depth of being."

There are a few typographical errors here and there, but these things are of little consequence in a work which deserves to be in the library of every physician interested in the medical history of his country, and which will undoubtedly prove a valuable reference book in working scientific and public libraries.

F. H. GARRISON

SURGEON GENERAL'S LIBRARY

A Revision of the Cotylosauria of North America. By E. C. CASE. Washington, Carnegie Institution, Publication No. 145. 1911. Pp. 122, 14 plates.

It is now more than thirty-six years since the first Permian or Permo-Carboniferous reptiles were made known from North America by the late Professor Cope, who until his death twenty years or more later published at frequent intervals papers dealing with Paleozoic land vertebrates, coming chiefly from the famous deposits in northern Texas. As a pioneer, his work, here as elsewhere, was, of necessity, largely based upon fragmentary and imperfect material, material largely obscured by an obdurate matrix that only long and skilful preparation could remove. Few, if any, forms were known to him in anything approaching perfection or even completeness. As an inevitable result he left the subject in more or less confusion, notwithstanding the many important facts which he discovered. Many of his types were never figured nor even adequately described. In more recent years, beginning with Professor Case's collection in

Texas in 1897, the additions to our knowledge of these old land vertebrates made by him and others have been very considerable and of profound importance in paleontology. But much of the confusion and doubt regarding many of the original types, for the most part preserved in the American Museum of New York City, could only be removed by a careful revision of the whole group, based upon original specimens. This Professor Case has given us of the so-called order Cotylosauria in the present paper. At the present time there is, perhaps, no group of vertebrates of deeper interest to the student of evolution than the primitive reptiles and amphibians of the later Paleozoic, the forms from which all later vertebrates, save the fishes, have been derived. The many problems of the evolution of the Amphibia, and the origin and "radiation" of the Reptilia, are, until other fields have been discovered, dependent chiefly if not almost wholly on the Permo-Carboniferous deposits of Texas and the Rocky Mountains. No classification of the reptiles and amphibians will ever command any great degree of respect until these faunas have been well worked out; and, inasmuch as many of the problems of these groups are fundamental ones in many respects for all higher vertebrates, the interest attached to such studies as the present may be easily understood.

Professor Case did a very acceptable piece of work in his revision of the Pelycosauria, or the higher reptiles of the same fauna, published a few years ago. In the present work he has revised systematically and morphologically the numerous genera and species that have been proposed of the cotylosaurian reptiles, a group usually called an order though not distinguishable by very important characters from the Pelycosauria or Theromorpha. The chief value of the paper is the information given of the fragmentary and often unrecognizable types of Cope, as interpreted in the light of a more advanced knowledge of the group, by descriptions, comparisons and illustrations. Not much new material has been described nor have many new forms been added that had not been published by himself

or others previously. He divides the order into four suborders, the Pareiasauria, Procolophonia, Diadectosauria and Pantylosauria, the last two new. While these terms will be convenient, the present writer doubts whether the distribution proposed of the families is really the best, or whether indeed there is really any need of classificatory terms between the family and order at present.

Dr. Case urges, what has now become apparent, that the Cotylosauria are far from being the beginning of the reptilian stem, that forms so diverse as those we already know from the base of the American Permian must have been long years in developing. Nevertheless they approach that beginning relatively close, and, until the actual beginning is found, must suffice as the basis for the classification of all later reptiles. The writer can not agree with the author in the interpretation of some of the cranial elements in these reptiles, but as that is a subject about which no two authors agree, Dr. Case's views are perhaps as good as those of others. Nor is he assured that the forms *Eosaurus* and *Saurus* really belong among the Cotylosauria. And, as regards the attachment of the ribs in these "microsaurian" forms, they are really not different from those of all the known Permian-Carboniferous reptiles.

The work has been brought out in excellent shape by the Carnegie Institution, and it will long remain as an indispensable one for all students of the early reptiles.

S. W. WILLISTON

The Home-life of the Osprey. By CLINTON G. ABBOTT. London, Witherby & Co. 1911. Pp. 1-56; 32 mounted plates.

This volume forms the third of an admirably planned series, designed to present, through the aid of pictures and a brief text, the most interesting facts about celebrities of the bird world. The American osprey is worthy of this distinction, and the field-work, upon which this biography is based, although "necessarily limited to the brief opportunities of a business man," has been prepared with commendable care. We venture to express the

hope that more business men, and representatives of the professions may in time come to reap the profits and enjoyments which an intelligent interest in natural history affords.

The author's studies were made on the coast of New Jersey, at Great Lake, North Carolina, and at that world-famous preserve for ospreys, Gardiner's Island, New York. This tract of 3,000 acres is three miles from the eastern end of Long Island, and is probably unique in that, as we are told, it has been in the possession of the same family for nearly 300 years, or since the time of its purchase from the Indians for "ten coats of trading cloath." It is now maintained as a general farm and preserve, with "a pleasing succession of rolling meadows, thick coverts, stately trees, lakes and grassy marshes." This remarkable island has been the immemorial home of fish hawks, and is now thought to harbor upwards of 200 of their massive nests. Moreover, these gigantic structures are reared with absolute freedom, in almost every conceivable situation, upon the shifting sands of the beach, upon great rocks, in trees or even upon the gable end of a deserted barn or shed. The author shows a nest built on a fence-post and another on a telegraph pole, while in parts of Connecticut these neighborly birds have often taken kindly to the old cart wheel reared aloft for their special benefit on the top of a high pole.

Ospreys are model parents, friendly to man, and exceedingly attractive at all times. Many characteristic attitudes in both young and adult are described and figured by Mr. Abbott, such as flying up the wind in returning to the nest, detouring, repeating and often alighting on any favorite perch other than the nest. Like other birds, they hold closely to the perch, upon which habit has fixed.

Mr. Abbott never saw the parents sprinkle their young with water, but Allen, an earlier observer of this species, found that they occasionally brought fresh seaweed to their eyrie. "Similarly, I have sincere doubts," says the writer, whether the "grateful shade, over the young, of the parent's outstretched wings, is not more accidental than inten-

tional." As a result of long observation we know that shielding is a common practise with nesting birds. It is probably something more than a heat-reflex, since it is most characteristic of the later period of nest-life, when it succeeds the more familiar brooding "habit." This spreading over the young, or shielding attitude, is useful like the other instincts, but whether it is "intentional" or not is quite aside from the main question. We might even have to qualify any sweeping statement that *brooding* was intentional. "Spreading," when away from the nest, is undoubtedly a reflex, and is often apparently due to heat, but birds will spread in a similar manner to dry off when wet.

Young ospreys are fed at long intervals, not oftener than twice or three times a day, though the rate of feeding possibly may vary somewhat with age. At one nest which the author carefully watched, meals were served at 7 P.M. and at 4.15 A.M. and 7 P.M. on the following day. At night the male guards the nest, while its mate broods.

The osprey is said by fishermen to descend four or five feet in the water to strike the flounder, which is often seen in its talons. Fish are always carried head foremost, either the bird's right or left foot being directed forward. It will be interesting to note that the largest capture which Audubon directly observed, was a weak-fish, weighing upwards of five pounds. This bird, he remarked, was barely able to rise from the water, and when shot at it immediately dropped its quarry. Moreover, it was this large and perfect specimen which Audubon introduced into his plate.

Nest-building begins in May and additions to the structure are made throughout the season. A nest once built and occupied is commonly held as a rightful and individual possession, and the structure tends to increase in bulk from year to year. The writer, however, finds that this is not invariably the case, and much more exact knowledge on the history of such nests is greatly needed. A nest of the osprey which was removed from Gardiner's Island to the New York Zoological Garden

weighed 400 pounds and it is thought that the largest nests may even reach the weight of half a ton. At this island the eggs are laid early in May, and two to three in number. Incubation lasts from 24 to 28 days, the young ospreys emerging in close furry down. Nest-life lasts from 5 to 6 weeks, and is over by early August.

We do not for a moment believe that ospreys or any other wild birds suffer the "mental anguish" about their young which the writer generously attributes to them, but we are not disposed to be overexact with work conscientiously done, and especially when a good moral lesson is enforced.

FRANCIS H. HERRICK

WESTERN RESERVE UNIVERSITY

A Text-book of Botany for Colleges and Universities. By members of the Botanical Staff of the University of Chicago, JOHN MERLE COULTER, Ph.D., Professor of Plant Morphology; CHARLES REID BARNES, Ph.D., Late Professor of Plant Physiology; HENRY CHANDLER COWLES, Ph.D., Associate Professor of Plant Ecology. Vol. II. Ecology. New York, Cincinnati and Chicago. American Book Company, octavo. Pp. x + 485 to 964 + 17.

A little more than a year ago the present writer noticed the first volume (Parts I. and II.) of this notable contribution to the American text-books of botany (SCIENCE, January 6, 1911), and suggested the probable early appearance of Part III. This saw the light about the holidays, and has been before the botanists of the country long enough to have already taken its place as one of the standard texts in its special department of botany. No doubt the first feeling of every botanist was one of surprise at the quite different mode of treatment given to the subject from that which has heretofore been accorded it. Some things hitherto regarded as ecological are entirely left out in Dr. Cowles's treatment or given very little emphasis. No doubt many an "ecologist" will rub his eyes as he looks about him in certain chapters for something familiar.

In an introductory chapter the author discusses his problem in such manner as to help us to see it from his point of view, starting with the remark that "ecology is a science in its beginnings." A little later he says "nor is it possible as yet to mark out its limits, for it overlaps to a greater or less degree every other field of biology and of physiography and geology as well." In spite of these difficulties he ventures a definition of ecology as "that phase of biology that endeavors to explain the origin, variation and rôle of plant or animal structures, and the origin and variation of plant or animal associations." This introductory chapter ought in fact to be very carefully read and reread by the student who wishes to know what it is that Dr. Cowles is putting before him under the name "ecology," for it will be evident very early in the use of the book that it is not at all like those that have preceded it, which means that this "ecology" is not the "ecology" of many other authors.

The general plan of the book may be seen in an enumeration of the contents of the eight chapters, as follows: (I.) Roots and Rhizoids; (II.) Leaves; (III.) Stems; (IV.) Saphrophytisms and Symbiosis; (V.) Reproduction and Dispersal; (VI.) Germination; (VII.) Plant Associations; (VIII.) Adaptation. If now the student will read carefully any of these chapters he will find that they deal almost entirely with structure and behavior, and it appears to be the author's deliberate purpose to present these as the material upon which the beginner in ecology is to work. That is, Dr. Cowles bases ecology upon morphology and physiology, just as some of us have been insisting for these past years during which a certain type of ecologists were leading wholly unprepared young people into hazy observations in the field.

It is noticeable that the author has pretty fully eliminated teleology, which had become so conspicuous in the ecological writings of some botanists, reminding one in extreme cases of the botany of the early part of the nineteenth century. This revival of teleology by the younger generation was not a little

disquieting to the older botanists, who rightly felt that it was a backward step in the science to return to a view or doctrine that had only so recently been abandoned. In Dr. Cowles's book there is no conscious leaning toward teleology, and for this scientific men owe him a debt of gratitude.

In like manner the author has subordinated the geographical phases of the subject, giving some portions scant notice. He has chosen to emphasize the plant individually, rather than the mass of individuals constituting a particular community of plants. This no doubt contributes to clearness and definiteness and there can be no question that the students who approach ecological studies from this side and in this manner will have much more lucid notions on the subject than those who were taken directly into the field for the study of "vegetation" and "formations." It will be interesting to see what effect this presentation of ecology will have upon its study in high schools and the smaller colleges, where too often it had degenerated into vapid lectures on the general aspects of the vegetational landscape much after the fashion of those formerly given to young ladies who "took botany" in the old-time female seminaries of a century ago.

One of the most helpful and suggestive chapters is that on Saphrophytism and Symbiosis (IV.), dealing as it does with all phases of the structural and physiological relation of the two organisms concerned. The treatment here is clear, and well calculated to lay a solid foundation in the mind of the beginner.

In the fifth chapter (Reproduction and Dispersal), while by far the greatest attention is given to these phenomena in the flowering plants, the subject is introduced by twenty pages on the behavior of the lower plants, the author's idea evidently being that even lower plants are worth while ecologically, especially as they are simpler and more easily understood. The treatment throughout the chapter has an air of freshness that is gratifying, much of the matter having been developed by the author in connection with his class work.

The short chapter on plant associations,

eight pages in all, will be disappointing to old-time ecologists, to whom, however, its brevity should be a suggestion that they have hitherto given overmuch emphasis to this phase of the subject.

A thoughtful chapter on "adaptation," in which the author gives his personal views on the subject, closes the book in such a manner as to leave the student in a properly humble state of mind, since it makes it clear that many of the "cock sure" conclusions of yesterday are improbable, or quite impossible.

A most useful, ten-page appendix contains a classified bibliography which will prove very useful to the student who wishes to go farther than the study suggested in the text.

SPECIAL ARTICLES

THE PHOTOELECTRIC EFFECT

READERS of SCIENCE may be interested in the following brief summary of some of the principal results of an investigation of the magnitude and distribution of the total kinetic energy of the electrons emitted when light falls on metals, considered as a function of the frequency of the light and of the nature of the metal. A fuller account of the investigation was communicated to the meeting of the American Physical Society at Boston on April 27.

Monochromatic ultraviolet light of various wave-lengths from a quartz-mercury arc lamp was allowed to fall on a small strip of the metal to be tested placed at the center of an exhausted conducting sphere. Measurements of the currents against various opposing potentials enable the distribution of the energy among the emitted electrons to be obtained directly. The experimental results may be analyzed and exhibited graphically by plotting the number of electrons having a given energy against the energy. These curves are nearly symmetrical about the axis of mean energy. The mean energy is very close to the most probable value of the energy. The probability of an electron having energy within a

given range changes very rapidly in the neighborhood, both of the maximum energy and of zero energy. The maximum energy, and also the range of energy, of the electrons emitted by light of a given frequency is approximately a linear function of the frequency.

For different substances the relation between the mean energy T_v and the frequency v of the exciting light is found to be $T_v = k_1(v - v_0)$. For sodium, magnesium, zinc, aluminium, tin and platinum $k_1 = 2.9 \times 10^{-27}$ erg. sec. v_0 is a constant characteristic of the substance. The above formula is a particular case of a more general relation $T_v = v\phi(v_0/v)$, where ϕ is a universal function of the argument, which was deduced theoretically by one of the writers. According to the theory the values of v_0 should be calculable from Planck's radiation constant h and the intrinsic potentials of the substances. The calculated values of $\lambda_0 = c/v_0$ are compared with those given by the photoelectric measurements in the following table:

	Na	Al	Mg	Zn	Sn	Bi	Cu	Pt
λ_0 (calculated)....	52.6	36.0	34.6	33.3	31.0	29.4	28.0	27.3
λ_0 (photoelectric)	57.0	39.5	36.5	36.1	33.8	33.1	29.7	29.0

Our measurements of the maximum energy T_m are probably less accurate and certainly more irregular than those of the mean energy; but they are all fairly near the linear relation $T_m = k_2(v - v_0)$. The values of v_0 are the same as before and k_2 is very near to 6×10^{-27} erg. sec. k_2 is thus about 10 per cent. less than Planck's constant h . We do not, however, wish to emphasize this difference, pending further investigation, as we realize that the accurate measurement of the maximum energy is a rather difficult problem. Bismuth and copper appear to have smaller values of both k_1 and k_2 than the other metals, but here again it is possible that further research will remove the difference.

If the laws which we have found to connect the frequency of the light with the maximum and mean energy of the liberated electrons hold up to the highest frequencies, it follows

that the frequency ν of Röntgen rays may be obtained from either of the equations

$$\nu - \nu_0 = \frac{T_v}{2.9} \times 10^{27} = \frac{T_m}{6} \times 10^{27},$$

where T_v is the mean energy and T_m the maximum energy of the electrons emitted when Röntgen rays fall on a metal. For these high frequencies ν_0 may be neglected compared with ν .

Our results are favorable to a theory of the photoelectric effect of the type of Einstein's¹ combined with the hypothesis that the difference in the work P for different substances is determined by the contact difference of potential.

PRINCETON UNIVERSITY

PRELIMINARY NOTE ON THE OCCURRENCE OF A SEX-LIMITED CHARACTER IN CATS¹

THE problems offered by so-called "sex-limited characters" have lately been attacked by several investigators who have found in many of the cases a possible explanation of the observed phenomena by considering one of the sexes a Mendelian homozygote for the "sex-producing" factor, while the other sex is considered a heterozygote.

The sex-producing factor is commonly designated by X , its absence by $-$. Thus one sex would be homozygous, XX , and the other would be heterozygous, $X-$. Certain cases have been found in which experimental results indicate that the female is homozygous, XX , while the male is heterozygous, $X-$, while in other cases the facts are best explained on the hypothesis that the female is heterozygous, the male homozygous. Interest increases as sex-limited characters are found in the higher animals, the inheritance of which follows one or the other of these formulae.

It has long been known that "tortoise shell" (a blotching of black and yellow, or

blue and cream) occurs in cats, in a vast majority of cases in the female sex. Doncaster² (1904) attempted to ascertain whether tortoise shell could be considered as a sex-limited character whose appearance conformed to the then existing hypotheses of sex-inheritance. He came to the conclusion that "tortoise" was merely the female form of heterozygote obtained in a cross between orange (yellow) and black animals. The male form of "heterozygote" was orange in certain crosses. Thus he found that (1) orange female \times black male gives tortoise females and orange males, but the reciprocal cross (2) black female \times orange male gives tortoise, black (and probably orange) sexes not stated. This last-named cross is crucial, for in it is contained the evidence that the male "heterozygotes" between orange and black are *not always orange, but may be black*. The writer has, in a very small way, carried on this cross. Thus four black females crossed with the same orange male have given a total of 15 young; of these 7 were males, *all being black*, and 8 were females, *all being tortoise; no "orange" animals appeared*. Here there is evidence that the cross of orange male \times black female produces male offspring, *all of which are black*, while Doncaster's evidence shows the reciprocal cross to produce male offspring, *all of which are orange*.

We must, therefore, suppose a reversal of dominance to occur in the reciprocal crosses unless we can use the hypothesis of sex-limited inheritance.

If we adopt, tentatively, the hypothesis that the female is a homozygote, XX , and the male is a heterozygote, $X-$, and if we suppose that black, B , is always coupled with the sex-producing factor, X , we should conclude that the black female is of the gametic constitution, BB , and that the black male is of the composition $B-$.

The yellow male lacks the factor for the production of black pigment in the coat and is of the gametic composition $Y-$, while the

¹ *Ann. der Physik.*, Vol. 17, p. 146, 1905.

² From the Laboratory of Genetics, Bussey Institution.

² *Proc. Camb. Phil. Soc.*, XIII., Pt. I., p. 35, 1904.

yellow female is *YY*. The constitution of these four parent forms would then be: *BB*, black female; *B—*, black male; *YY*, yellow female; and *Y—*, yellow male.

If then we make the cross yellow male, *Y—*, \times yellow female, *YY*, all the young should be yellow, one half being males and one half females. In this cross 5 young have been obtained, 3 males and 2 females, all yellow.

If we make the cross black female, *BB*, \times yellow male, *Y—*, we have in *F*₁ two types of individuals, viz., *BY*, tortoise females, and *B—*, black male. Theoretically these two types should be formed in equal numbers; actually the tortoise females are 8, the black males 7. The reciprocal cross is yellow female, *YY*, \times black male, *B—*; *F*₁ has two types of individuals, viz., *BY*, tortoise female, and *Y—*, yellow male. This expectation coincides with the facts observed by Doncaster. We have, however, an important cross under way which must be carried out more fully before the hypothesis, given above, can be considered as proved. This mating is: tortoise female, *BY*, \times yellow male, *Y—*. The expected result is *BY*, tortoise females; *YY*, yellow females; *B—*, black males; and *Y—*, yellow males. One litter has been obtained from this cross; it contained one tortoise female, one black male and three yellows (dead), the sex of which was unfortunately undetermined before the caretaker discarded them. It is interesting to note that Doncaster cites this mating as producing "blacks, tortoises and oranges," though he does not record the sexes.

The cross tortoise female \times black male has been recorded by Doncaster. It gave tortoise females, orange males, black females and black males. By the hypothesis here suggested this is to be expected. Thus tortoise female, *BY*, \times black male, *B—*, should give *BB*, black females; *B—*, black males; *Y—*, yellow males; and *BY*, tortoise females.

Male "tortoise shells" occasionally occur, and it seems probable from their rarity that they are due to some distinct mutation such as that which produces tortoise guinea-pigs,

and not to heterozygosis between black and yellow. Theoretically, if such were the case, tortoise females of a similar nature might be produced. Such animals would be indistinguishable externally from the common form of "tortoise," but would differ in gametic composition, and therefore in their behavior in crosses.

So far as first-hand evidence goes the observed experimental facts are best explained by the hypothesis outlined above, which considers the factor for black coat color in cats to be linked with the *X* element, and therefore to be sex limited. Doncaster's suggestion that tortoise is merely the female heterozygote obtained in crosses between yellow and black would not explain the fact that reciprocal crosses of black with yellow produce males differing in color, one cross producing black males, the reciprocal cross producing yellow males. Indeed the last-mentioned fact in itself makes the case unique among mammals. If, then, the hypothesis of "sex-limited" characters outlined above is found to be substantiated by the cross, tortoise female \times yellow male, we shall have established a case of the same general character as those described by Morgan as occurring in *Drosophila*. Further experiments bearing upon the matter are in progress.

April 23, 1912

THE AMERICAN PHILOSOPHICAL SOCIETY

THE annual general meeting of the American Philosophical Society was held in the rooms of the society at Philadelphia, April 18 to 21 inclusive, and constituted perhaps the most notable series of sessions ever held by the society. The papers were all of a high order of merit and presented in many cases for the first time the results of original investigation by the authors.

The meeting was opened on Thursday afternoon, President W. W. Keen, LL.D., in the chair, when the following papers were read:

Some Former Members of the American Philosophical Society: THOMAS WILLING BALCH.

The writer said that besides Franklin, the founder of the society, Washington, Jefferson and Cleveland were members. Many other political

men were members: John Dickinson, Albert Gallatin, De Witt Clinton, Alexander James Dallas, Thomas Francis Bayard and Carl Schurz, for example. The painters, Benjamin West, Charles Wilson Peale and Thomas Sully, belonged to the society. Of jurists, John Jay, John Marshall and Roger Brooke Taney were members. Among others whose names are on the roll of the society were: Joseph Bonaparte, King of Spain; Louis Philippe, King of the French; George Gordon Meade, the victor of Gettysburg; Commodore Wilkes, Bishop Charles Magnus von Wrangel, of the Church of Sweden; the Rev. John Witherspoon, of the Church of Scotland and president of Princeton. Among publicists, John Stuart Mill was a member, as also Noah Webster, de Tocqueville, Henry Wheaton, President Woolsey of Yale, Sir Henry Sumner Maine, Henry Charles Lea, Dupont de Nemours, Michel Chevalier. The writer showed that the society had recognized all knowledge in choosing its members.

The Diary of a Voyage to the United States, by Moreau de Saint Méry: STEWART L. MIMS. Introduced by Mr. J. G. Rosengarten.

Mr. Mims told the story of his good fortune in finding the diary in the Colonial Archives at Paris, where it had lain covered with dust, all but unnoticed and forgotten, for three generations. The author of the diary was born at Fort Royal, Martinique, in 1750, went to Paris at nineteen to study law and returned to Cap Français (to-day Cape Haiti) in the French colony of St. Domingo, where he practised law for eight years and was then elected to the Conseil Supérieur. The task of codifying the laws of St. Domingo called him back to Paris, where he published successively, from 1784-1790, the six volumes of his famous collection of laws concerning the French West Indies. At the outbreak of the French Revolution he became an ardent champion of the Revolutionary cause. He was made one of the electors of Paris, who governed France during the space of one month. It was as their president that he was "King of Paris during three days." With the accession of Robespierre to power Moreau was forced to flee from Paris into Normandy and later to Havre, whence he took ship for the United States on November 9, 1793. Owing to strong head winds and many storms, his vessel did not reach Norfolk before March 8, 1794. He remained as an exile in this country until August, 1798, when he returned to France.

It is of this sojourn in America that the diary

records the story. After calling attention to the value of certain passages where the author records his impressions of such cities as Norfolk, Baltimore, New York and Philadelphia, and to other passages containing the author's comments upon such public men as Washington, John Adams and Alexander Hamilton, Mr. Mims laid special stress upon the interesting material which the diary contains for Philadelphians.

Moreau de St. Méry spent no less than three years and ten months of his exile in this city, maintaining a bookstore and printing shop at Front and Walnut Streets. He offered for sale in his bookstore a large collection of foreign books which attracted many cultured Philadelphians. At his printing press were published in French, besides other works, three of his own well-known books, "La Danse," "La description de la partie espagnole de St. Dominique" and "La description de la partie française de St. Dominique." Besides, at this same press was published in French from October 15, 1795, to March 14, 1796, a daily newspaper, entitled "Le Courrier de la France et des Colonies," a most unique publication which recorded for the exiles the latest news from France and the West Indies, and served as an organ for the society of Frenchmen who resided then in Philadelphia.

Moreau's shop became in a sense the place of rendezvous for such famous exiles as Talleyrand, Beaumetz, Blacou, de Noailles, Talon, la Rochefoucauld de Liancourt, who had taken refuge "in the ark of Noah," which one of them wittily called Philadelphia at that time. In this connection, the speaker called attention to the very intimate relations existing between Talleyrand and Moreau, stating that the diary contained no less than seventeen unpublished letters from the hand of Talleyrand which were written to Moreau. One passage was quoted from the diary which gave a most striking picture of the famous diplomat, sipping away at a glass of good old Madeira and chatting with his congenial companions, both oblivious of time, until the good wife of Moreau came to drive away the garrulous bishop, reminding him that he might spend his morning lazily in bed, whereas his friend must be up early at the daily duties of his shop. It is interesting to add that Talleyrand, after he had regained power in France, never forgot the friend of his days of exile, but succeeded in reopening the doors of France for his return and providing for his welfare in later life.

In conclusion the speaker expressed confidence that the publication of the diary at the Yale University Press during the coming summer would prove of interest to all students of Philadelphia's history and would add another diary of value to the many interesting records of travel by foreigners in the United States.

The Legendary and Myth-making Process in Histories of the American Revolution: SYDNEY GEORGE FISHER.

Bardaian and the Odes of Solomon: WILLIAM ROMAINE NEWBOLD.

Sumerian Bookkeeping Five Thousand Years Ago (Illustrated): GEORGE A. BARTON.

The Political Ideals of Ulrich von Hutten: KUNO FRANCKE.

Recent German criticism is inclined to undervalue the services rendered by Ulrich von Hutten to the cause of liberalism. In his personality German humanism finds its most ravishing and irresistible expression. In him the Erasmusian enlightenment burns into a revolutionary power. It is a mistake to think of him primarily as an ally of the Lutheran reformation. Hutten would have been the last to submit to the dogmas of the Lutheran church. His aim was the political and intellectual reconstruction of Germany. Abolition of the monasteries, confiscation of church property, secularization of the schools and the higher institutions of learning, safeguarding of free thought and free inquiry, centralization of the empire, limitation of the power of the territorial princes, creation of a powerful public opinion based upon an alliance of the cities and the knighthood—these were his political ideals. If he failed in his efforts to put these ideals into practise, he has at least given a powerful stimulus to the modern conception of the state as the legitimate upholder of liberal culture and spiritual progress.

Some Anthropological Aspects of the Brain with Reference to Race, Sex and Intellect: EDW. ANTHONY SPITZKA.

A discussion of the weight and morphologic appearances of the human brain and its several parts resulting from a series of studies upon specimens of various races and notable individuals, including those of Andamanese, Nicobarese, Chinese, Eskimos, Negroes, as well as eminent scholars from civilized nations. Particular attention is called to the relative redundancy of certain association areas of the cerebral cortex in eminent men and women and also to the relatively larger

callosum, or great commissure associating the hemispheres of the brain. The lecture was illustrated by lantern slides.

Waterway Conservation: LEWIS M. HAUPT.

This paper treats of population as the basis of wealth and points out the enormous increase which must follow in the coming century, if the existing ratio continues, which would give a population of nearly 600,000,000 by 2012 and which will seriously tax our political and social conditions, while it also increases enormously the wealth due to the "unearned increment" and the desire to exploit our natural resources.

The great increase in transportation, which has almost doubled in the last decade, is cited as indicating the inability of the overland carriers to cope with the future demand and the absolute necessity of supplementing the railroads by greatly improved water- and highways is urged as a measure of relief and regulation.

Attention is directed to the efforts to secure conservation by statute laws which have become so intricate that great differences of opinion have arisen as to their interpretation, scope and application and a corresponding paralysis has resulted between state and governmental jurisdiction, thus retarding development and increasing the cost of living.

Violations of natural and physical laws have also resulted in great floods and consequent devastation, as is being forcibly impressed by the trail of disaster along the Ohio and Mississippi rivers at the present time, which have overtopped the levees with a lesser discharge than in former years, due to the closure of the outlets and confining of the sediment to the bed of the streams, by the extension of the levees.

These conditions are the sequences of the centralization of authority and control in the general government over all the waters of the country and the general demand from all sections for national appropriations from the federal treasury, which can not be met, and result in sectional jealousies and political pressure for patronage to the great detriment of local initiative and of open competition by states and localities in immediate need of relief.

The illustrations accompanying the paper showed how the energy of currents might be utilized to create automatic channels and remove bars in rivers and harbors at much less cost both for construction and maintenance than by the current means of dredging or the use of extensive jetties

in pairs, which obstruct the tides and create deposits in the pathway of commerce, thus increasing the cost.

On Thursday evening a celebration of the centenary of the introduction of gas as an illuminant, under the auspices of the American Philosophical Society, the Franklin Institute, the American Chemical Society and the American Gas Institute, was held in the hall of the Franklin Institute, Philadelphia, with President Keen in the chair.

A paper on "By-products in Gas Manufacture," by Charles E. Munroe, was read.

FRIDAY, APRIL 19—MORNING SESSION

President Keen in the chair

Hereditry of Feeble-mindedness: HENRY H. GODDARD. Introduced by Dr. Henry H. Donaldson.

The Inheritable Factors of Epilepsy: DAVID F. WEEKS. Introduced by Dr. Henry H. Donaldson.

Is the Control of Embryonic Development a Practical Problem? CHARLES R. STOCKARD. Introduced by Dr. Henry H. Donaldson.

Many deformities occur among animals in nature and a great number of deformed human beings are born. Many other individuals suffer from minor defects in bodily structure. These defects are often internal and may be unknown to their possessor, yet they frequently give rise to disease conditions which sometimes actually result in death. There are, for example, many congenital defects of the heart and other parts of the circulatory system, digestive tract, reproductive organs and developmental arrests may occur in almost all parts of the body.

These conditions must be regarded as a structural disease which causes the death of a number of children before they are born and handicaps many others throughout their lives. The cause of such defects must be ascertained, then a possible means of control may be found.

Observations on human families and experiments on lower animals prove that these conditions are due to one of two causes as the case may be. First, the embryo may have developed in an unfavorable chemical environment; or secondly, the germ cells of one or both parents may have been defective.

When the eggs of lower animals are treated with various poisons during their development they give rise to monstrous individuals. For example, when developing fish's eggs are treated for a short time with alcohol in some cases as many as 98 in 100

of the eggs give rise to fish which show almost all known deformities of the brain, eyes and other parts of the nervous system.

Guinea-pigs have been put into a state of chronic alcoholism and when such animals are mated either together or with normal individuals the resulting offspring are greatly affected. Many are aborted early in development, or reach term and are then born dead. Only a few are born alive and the great majority of these die after a short time, showing many nervous disorders and dying in convulsions.

A normal female when mated with an alcoholic male gives an almost equally poor result. This shows that the paternal germ cells are affected by the alcohol and are thus rendered unable to give a normal combination and abnormal offspring are produced.

Abnormal and deformed individuals may thus be artificially produced at will and the provoking cause is proved to be an unfavorable chemical environment acting on the germ cells of the parent or directly upon the embryo. The proposition of reversing the experiments thus presents itself, and some mode of treatment or control should be devised by which parents may be put into the proper state to produce as nearly as possible a normally vigorous offspring. Enough is known at present to make the control of development possible to a slight degree at least.

An Avian Tumor in its Relation to the Tumor Problem: PEYTON ROUS. Introduced by Dr. Alexander C. Abbott.

The paper reports the results of an experimental investigation into the cause of a malignant tumor. For the work a sarcoma of the chicken has been employed. This growth is transplantable from fowl to fowl, and presents the typical picture of a malignant tumor. It has been studied under many different conditions, not only in the adult fowl, but, by a special technic, in the chick previous to hatching.

Attempts to isolate a cause for the sarcoma have been successful. By filtration, or by drying, there can be separated from the living tumor tissue an agent which will produce the growth in fowls previously healthy. This active agent has not been directly observed, and is in all probability ultramicroscopic, since it will pass through filters which hold back minute bacteria. Its properties identify it as a living organism. In giving rise to a tumor it seems able to act only exceptionally and at points and upon tissues which have been

injured in some way. This dependence on a preliminary tissue derangement explains why the disease is not infectious in the ordinary sense.

The chicken sarcoma, like the tumors in general, can not^{be} be transmitted to other species; and the facts with regard to its cause must not be taken as applying directly to the tumors of other creatures. But these facts constitute the first demonstration of the cause of a malignant tumor, and they not unlikely illustrate a general truth.

Protein Poison: Its Preparation and Its Nature:

VICTOR C. VAUGHAN.

It has long been known that the protein molecule contains a poisonous group. This has been demonstrated by the administration of foreign proteins, parenterally, to heterologous animals. It has also been shown that peptones are poisons when injected subcutaneously and intravenously. The writer, together with Dr. Wheeler in 1903, succeeded in splitting up the protein molecule so as to get a highly poisonous body. This has never been obtained in a state of chemical purity, and its exact composition is not known. Its effects upon animals have been closely studied, and it may be prepared from all kinds of proteins, bacterial, vegetable and animal.

Bacterial Vaccines, with Special Reference to Typhoid Prophylaxis: FREDERICK F. RUSSELL.

Introduced by Dr. Alexander C. Abbott.

Alternate Life: ALEXIS CARRELL.

Dynamical Theory of the Globular Clusters and of the Clustering Power Inferred by Herschel from the Observed Figures of Sidereal Systems of High Order: T. J. J. SEE. By title.

Some Notes on Persian Mystic Poetry: A. V. WILLIAMS JACKSON.

FRIDAY, APRIL 19—AFTERNOON SESSION

Vice-president William B. Scott in the chair
Exhibition of Volumes of Illustrations of North American Vegetation: JOHN W. HARSHBEEGER.
History of the Fungus of the Chestnut-tree Disease: WILLIAM G. FARLOW.

The Classification of the Black Oaks (Illustrated): WILLIAM TRELEASE.

Attention to bud and fruit characters has led to a classification of the black oaks quite different from their usual arrangement according to leaf-form, and five groups of species are recognized, three of the eastern states, one of the southwest and one of the Pacific states. The eastern groups are the black oaks (black jack, turkey oak, Spanish oak and quercitron), scarlet oaks (scarlet oak, gray oak, Hill's oak, red oak, Texas red oak and

bear oak) and swamp oaks, these two sets, the water oaks (water oak, pin oak and Stone Mountain oak) and willow oaks (shingle oak, willow oak, laurel oak, running oak, cinnamon oak and myrtle oak). The southwestern olive oaks (Emory's oak and white-leaf oak) and the Californian holly oaks (evergreen oak, highland oak and Kellogg's oak) are less related to one another and to the eastern black oaks than these are to one another, and appear to have originated independently of these.

The Mammals of the Patagonian Miocene (Illustrated): WILLIAM B. SCOTT.

Illustrations of Remarkable Cambrian Fossils from British Columbia (Illustrated): CHARLES D. WALCOTT.

Dr. Walcott described a very remarkable and ancient fauna that he found in connection with geological explorations in the higher Rocky Mountains of British Columbia. From a camp at 7,000 feet elevation, he climbed a thousand feet to a ledge of rocks where the ancient Cambrian fossils are so perfectly preserved that the internal anatomy of many of the worms and crabs may be reproduced by photography.

His description of the fossils was illustrated by lantern slides made direct from the photographs of specimens representing over fifty genera heretofore unknown. The bay in which the mud was deposited, which now forms the rocks containing the fossils, was connected with the open ocean, and at the spot where the fossils were found the waters must have swarmed with the invertebrate life of the time. No fishes or other vertebrates were found to have existed at this ancient epoch. The earliest vertebrate remains known are several thousand feet higher up in the strata, and are many thousands of years younger than the Burgess shale fossils.

The marine worms are so perfectly preserved that they show not only the exterior form, but the interior intestine and the long proboscis which the worms thrust out through the mouth to secure food and to aid in drawing themselves through the mud.

The crabs show the intestinal canal, liver and a beautiful series of legs, gills and claws connected with the appendages about the mouth.

Specimens of *Medusæ*, or jelly fish, are beautifully preserved, even to the details of the thread-like swimming muscles. Dr. Walcott also showed upon the screen illustrations of the sponges, and many other rare forms of life.

Some Considerations Bearing upon the Origin of Lava (Illustrated): WILLIAM H. HOBBS.

The ideas which are generally held concerning the origin of lava have all gone out from the idea of a liquid interior to the earth. It has, however, been shown in recent years that the earth can not have a fluid interior, but on the other hand must be as rigid as a ball of glass of the same size. Within the earth the temperatures of the rock would easily melt it under surface conditions, but the pressure from the super-incumbent load elevates the point of fusion and so keeps the rock rigid, or as we might say "solid," though realizing that the condition may in many respects be quite unlike that of bodies at the surface of the earth. There must, however, be local and probably temporary reservoirs which supply the lava which exudes or is rejected from volcanoes. It is shown in the paper that the position of active volcanoes, particularly about the Pacific, suggests that the lava reservoirs which supply their lava have been due to local reliefs from pressure beneath arches of strong formations developed in the process of mountain making. The relative strengths of different sedimentary formations lead inevitably to the conclusion that the type of formation which thus fuses and produces lava, is what is known as shale or slate. Studies of the chemical composition of igneous rocks, which compositions are limited in range, support this view; and the study of the gases which lavas give off affords some further striking confirmations of the theory.

Recent Archeological Discoveries in Peru (Illustrated): HIRAM BINGHAM. Introduced by Mr. Henry G. Bryant.

The Discovery of the Continent of Antarctica by Americans—An Historical Vindication: General ADOLPHUS W. GREELY.

The speaker spoke of the unfamiliarity of the people of the United States with early American explorations of the South-polar regions, historical importance of vindicating America's title to the earliest discovery of the Antarctic continent, and to the first explorations that discovered and recognized its continental extent; discovery in 1821 of the northernmost lands of Antarctica, by Captain N. B. Palmer, a Connecticut sealer. Palmer Land was charted by George Powell with South Shetlands in 1822, and recognized by France in 1824. A voyage in 1831 of Master (retired) John Biscoe, R.N., was referred to, whereby Palmer Land was replaced on

British charts by Graham Land, named after the first lord of the admiralty. Palmer Land, ignored in the British Antarctic Manual, 1901, is recognized by only two lines in the Americanized Encyclopedia Britannica, 1911, which gives a column to Biscoe and Graham Land.

Emphasis was laid on Wilkes's discovery of extended and widely separated lands in 1840, with their recognition as forming the Antarctic continent, ignored by Capt. J. C. Ross in 1843, discredited by Encyclopedia Britannica in 1875, and declared non-existent by Capt. R. E. Scott, R.N., in 1905. Meanwhile Sir Clements Markham claimed in 1889 the honor of discovering the continent for Ross. British Antarctic Manual, 1901, admits the existence of one point (Knox Land). Mill in 1911 Encyclopedia Britannica admits in general that Wilkes's discoveries are to be indefinitely accepted. Occupation in 1912 by Mawson's Australian expedition of Adelie Land and Termination Land, vindicates Wilkes. Importance of incorporating these facts in appropriate American text-books was urged as a patriotic and educative duty.

The Interrelations of Eight Fundamental Properties of Classes of Functions: ARTHUR D. PITCHER. Introduced by Professor Eliakim H. Moore.

On Friday evening Professor R. W. Wood, of Johns Hopkins University, delivered a lecture before the society and guests at the College of Physicians on "The Study of Nature by Invisible Light, with Especial Reference to Astronomy and Physics."

The lecture was followed by an informal reception.

On Saturday morning at 9:30 o'clock an executive session was held in the hall of the society at which candidates for membership were balloted for. As a result of the election the following new members were announced: Albert T. Clay, B.A., Ph.D., New Haven; George W. Crile, M.D., Ph.D., Cleveland; Arthur Louis Day, Ph.D., Washington; Edward Curtis Franklin, Ph.D., Washington; John Grier Hibben, Ph.D., LL.D., Princeton; G. Carl Huber, M.D., Ann Arbor; James Furman Kemp, Sc.D., New York; Arthur Henry Lea, B.A., Philadelphia; John Matthews Manly, Ph.D., Chicago; Edward Bennett Rosa, Sc.D., Ph.D., Washington; Frank Schlesinger, M.A., Ph.D., Allegheny, Pa.; George E. de Schweinitz, M.D., Philadelphia; Frederick Winslow Taylor, M.E., Philadelphia; Roland Thaxter, A.M., Ph.D., Cambridge, Mass.;

Oswald Veblen, Princeton; George Friedrich Julius Arthur Auwers, Ph.D., Berlin; Wilhelm Ostwald, Sc.D., LL.D., Leipzig; Magnus Gustaf Retzius, Stockholm.

SATURDAY, APRIL 20—MORNING SESSION

President Keen in the chair

Some Geochemical Statistics: FRANK W. CLARKE.

The author first discussed the average composition of the igneous rocks, and then compared them with rocks of sedimentary origin. From the amount of soda lost by the decomposition of the igneous rocks, and the amounts retained by the sedimentaries or leached into the ocean, he showed that about 78,000,000 cubic miles of the primitive crust of the earth had been decomposed, forming a mass of rock consisting of about 80 per cent. shales, 15 per cent. sandstones and 5 per cent. limestones. He next compared the rate at which river waters transport dissolved salts to the ocean, with the composition of the ocean itself, and from these data computed the probable age of the earth since the continents assumed their present form at something near 83,000,000 years. The saline matter of the ocean alone amounts to about 5,000,000 cubic miles, or enough to cover the entire surface of the United States with a solid mass a mile and three quarters thick. The rate at which sediments are being deposited in the ocean was also determined, and found to be about 0.000027 inch annually.

Some General Results of the Work of a Century on the Atomic Weights of the Chemical Elements: GUSTAVUS D. HINRICHS.

Absorption Spectra and the Solvate Theory of Solution (Illustrated): HARRY C. JONES.

A large number of lines of evidence have been brought to light in the laboratory of the author, all pointing to the conclusion that a dissolved substance combines with more or less of the solvent in which it dissolves, about 7,000 solutions have now been studied with respect to their power to absorb light. It has been found that a given colored compound dissolved in different colorless solvents absorbs light very differently in the different solvents. This is interpreted as being due to a combination of the different solvents with the dissolved substance, forming the different compounds which absorb light differently. The bearing of this work on the nature of solution is important, and solution is the most important condition known to man from the standpoint of natural science in general.

Matter in the pure homogeneous condition does not enter into chemical reaction. It becomes active chemically only when dissolved. Chemistry, biology and geology owe their existence to matter in the dissolved state, and any light thrown on the nature of solution is of importance for the natural sciences in general.

The theory of solution hitherto held has been found to be insufficient, not applying to the very solutions that give us natural science.

In dealing with solutions we must always take into account the part of the solvent combined with the dissolved substance.

The Classification of Carbon Compounds: MARSTON T. BOGERT.

The subject is considered primarily from the standpoint of classification for purposes of instruction in organic chemistry. The various ways in which carbon compounds have been classified from time to time are traced historically, from the earliest period to the present, and the author expresses himself in favor at the present day of a classification based on chemical structure, grouping together all compounds of essentially similar function. Thus, all hydrocarbons, saturated and unsaturated, acyclic and cyclic, should be considered together, all simple halogen derivatives, and so forth. The author has used this method with his students at Columbia University for the past ten years and has found it very satisfactory.

An Autocollimating Mounting for a Concave Grating (Illustrated): HORACE CLARK RICHARDS.
Thermal Relations of Solutions: WILLIAM F. MAGIE.

The heat capacity of electrolytes dissolved in water is related to the temperature change of the heat of dilution. Experiments to demonstrate this were described and it was pointed out that the heat of dilution is a difference between two quantities of heat—one evolved in an amount proportional to the absolute temperature—the other absorbed in an amount independent of the temperature. One of these quantities is proportional to the dissociation which occurs on dilution and measures the energy lost by the solute as its ions combine with water. The other involves as a part of its value the heat absorbed by the dissociation.

A formula for the relations of the osmotic pressure to the temperature was proposed, from which the heat of dilution can be deduced. It was shown for solutions of common salt that the constants of this equation can be calculated from the freezing points and the boiling points of the solution, and

that they lead to the observed values of the heat of dilution.

The special significance of these relations lies in the strong support which they give to the theory that the molecules and ions of a salt in solution are associated or combined with the molecules of water.

The Measurement of Temperature up to 1750° C. (Illustrated): ARTHUR L. DAY. Introduced by Professor William F. Magie.

The gas thermometer is the standard thermometer in terms of which all temperatures are defined.

The gas thermometer problem at the present stage of its development has become primarily a problem for experimental study with two definite purposes, one to increase the accuracy of the measurements, the other to increase their range. The range through which temperatures can now be determined in terms of the fundamental definition (the expansion of gas under constant volume or pressure) has now reached nearly to the absolute zero downward, and to 1550° C. upward. The present investigation is concerned with the higher temperatures lying between 300° and 1550°. The accuracy attained in the present investigation within this region is about 0.2° in the vicinity of 300° and 2° at 1550°.

For the purpose of establishing temperatures of reference in this region for general use, the following constants have been determined:

Cadmium (melting point)	320.8 ± 0.1
Zinc (melting point)	419.3 ± 0.1
Sulphur (boiling point)	444.5 ± 0.1
Antimony (melting point)	629.8 ± 0.2
Silver (melting point)	960.0 ± 0.7
Gold (melting point)	1062.4 ± 0.8
Copper (melting point)	1082.6 ± 0.8
Li ₂ SiO ₃ (melting point)	1201.0 ± 1.0
Nickel (melting point)	1452.3 ± 2.0
Palladium (melting point)	1549.2 ± 2.0
Platinum (melting point)	1752.0 ± 5.0

Selective Scattering Reflection and Absorption by Resonating Gas Molecules (Illustrated): ROBERT WILLIAMS WOOD.

Some Observations on the Transmission of Sound through Walls: ARTHUR GORDON WEBSTER.

New Magnetic Charts of the Indian Ocean (Illustrated): LOUIS A. BAUER.

The charts exhibited embody the results of magnetic observations made during the summer and fall of 1911 on board the non-magnetic yacht *Carnegie* operating under the direction of Dr. L.

A. Bauer, director of the department of terrestrial magnetism of the Carnegie Institution of Washington.

The necessity of the new charts arose from the exceptionally large errors found in the magnetic charts at present in use by mariners. Thus, for example, the errors in the charted compass directions for two of the most recent charts approximate respectively four degrees and six degrees, though one of the charts was issued as recently as 1910. With the exception of a few values found by the vessel used in the Pacific Ocean work, namely, the *Galilee*, these are the largest errors thus far revealed. In the portions of the Atlantic Ocean covered by the *Carnegie* the compass chart errors have generally been below two degrees, though running at times up to two and a half degrees.

The chart errors in the compass directions are usually found to be systematic, that is, in the same direction for large stretches, and are to be ascribed largely to erroneous secular changes allowed for in attempting to bring previously observed values up to date.

Thus, for example, by comparing the *Carnegie* values of 1911 with those obtained on board the German Antarctic vessel, the *Gauss*, in 1903, it is found that the north end of the compass moved to the eastward (hence diminished west declination) at the average rate of about 11' per year off the southeast end of Africa, whereas in the vicinity of the islands of St. Paul and New Amsterdam in the Indian Ocean (lat. 35° 16' S., long. 74° 46' E.) it moved to the westward (increased west declination) at the average rate of about 13' per year. The charts give secular changes of only about one fourth of these amounts, so that the error of reduction in but ten years amounts almost to 2°. It is doubtless due to these large secular changes disclosed in the Indian Ocean, and especially their rapid variation with geographic position, that the large errors mentioned have crept into the charts.

The errors in the other magnetic elements, while of less importance to the mariner, are of consequence to theoretical investigations regarding the earth's magnetism. In the magnetic dip, the errors on the present cruise have amounted at times to 4°, and in the horizontal intensity to about one twentieth part. While some of the results derived from previous analyses of the earth's magnetic field have pointed to the possibility of large and more or less systematic chart errors, it was not suspected that they would reach

the magnitude disclosed by the work of the *Galilee* and of the *Carnegie*.

The *Carnegie* is at present making a circum-navigation cruise and is expected back in New York towards the end of 1913, having left the same port in June, 1910. Up to February 1, 1912, this vessel has already covered about fifty thousand miles. She left Manila on March 23, in command of W. J. Peters, bound for the Fiji Islands.

Owing to the non-magnetic construction of the *Carnegie* and the absence in consequence of any deviation corrections, it is possible to obtain and communicate results expeditiously. The data are promptly transmitted to the chief hydrographic establishments issuing magnetic charts in order to enable them to make the necessary corrections from time to time.

SATURDAY, APRIL 20—AFTERNOON SESSION

Vice-president Edward C. Pickering in the chair
Symposium on Stellar Spectroscopy—Radial Velocity (Illustrated); WILLIAM W. CAMPBELL.

Our knowledge of motions of the planets around the sun and of the satellites around the planets has been reduced to a system, of remarkable accuracy. Knowledge concerning the motions of the stars is growing rapidly: shall we be able to develop this knowledge into a system?

Stellar motions are studied through their components known as *proper motions* and *radial velocities*. Proper motion studies of the stars have been fruitful, but limited in value by our ignorance of stellar distances. Radial velocities have the advantage that they are independent of stellar distances.

All observed stellar motions contain components due to the motions of the observer. The first step in studies of stellar motions is to determine the elements of the solar motion and to eliminate its effects from the observed motions of the stars, thus leaving the motions with reference to the stellar system.

The direction of the solar motion has long been fairly well known: the solar system is approaching a point 10° or 15° southwest of *Vega*. The speed determined from 1,200 radial velocities is $19\frac{1}{2}$ kilometers (12 miles) per second.

The velocities of the stars are functions of their spectral classes; i. e., of their effective ages. The young stars are traveling slowly—12 kilometers per second, on the average; the middle-aged stars more rapidly— $28 \pm$ km. per second; and the old stars the most rapidly— $34 \pm$ km. per second. Our sun,

as a middle-aged star, is traveling with a speed, $19\frac{1}{2}$ km. per second, far below the average of its class. We do not know why stars increase their speeds as they grow older.

Amongst the brighter and nearer stars those resembling our sun in effective age predominate; and they partake somewhat of the solar motion. Neglecting these brighter middle-aged stars, the remaining stars form a fairly homogeneous mixture of stars of all ages.

Radial velocity data increase our estimate of the scale of the universe about 50 per cent. above proper motion estimates.

Observers with great telescopes have found that one star in eighteen, down to the 9th magnitude, is a double star, and that one in eleven or twelve brighter than the 5th magnitude is double. The spectrograph has shown that *at least one star in four*, down to the 5th magnitude, is a double star; with components so close together that they have never been seen separately in our most powerful telescopes. For young stars the observed proportion is greatest, the components are closer together, and the orbits are rounder. For the old stars the proportion of observed doubles is smallest, the orbits are larger and more elongated. The proportion of discovered doubles, especially amongst the old stars, is rapidly increasing. Conclusion: Double stars have been joined and developed from parent gaseous masses, substantially as mathematical astronomers had predicted. There is the utmost need for cooperation amongst astronomers in observing the radial velocities of stars between the fifth and seventh magnitudes.

Objective Prism Spectra: EDWARD C. PICKERING.
On the Prospect of Obtaining Radial Velocities by Means of the Objective Prism: FRANK SCHLESINGER.

Relations between the Spectra and other Characteristics of the Stars (Illustrated): HENRY N. RUSSELL.

Among the stars whose distances can be measured with some approach to accuracy, and whose real brightness can thus be determined, there exists, with few exceptions, a very marked relation between the actual brightness and the class of spectrum. The stars of spectrum A (resembling Sirius) are on the average about 50 times as bright as the sun; those of spectrum F5 (like Procyon) about five times as bright as the sun; those with spectra like the sun's (class G) are nearly equal to the sun in brightness; while the orange stars of spectrum K average only one sixth as bright, and

the red stars of classes K5 and M are usually less than one fiftieth as bright as the sun. On the average, the stars of each spectral class are seven times as bright as those of the following class. This rule holds true both for the stars relatively near us, whose individual distances can be measured, and for those belonging to clusters whose distances are known.

There exist, however, many stars of great brightness, of all spectral types, which are almost all so remote that their distances can not be accurately measured. From the best available data, these stars appear to be on the average from 100 to 250 times as bright as the sun, without much difference between the different spectral types.

Among the stars redder than the sun, these two groups, of different brightness, are widely separated; but among the whiter stars they run together, and become identical for the whitest stars (class B), which average more than 250 times as bright as the sun.

In the cluster of the Pleiades (whose distance has so far been unknown) all spectral classes from B5 to G are represented, and the relative brightness of the different types follows very closely the law which holds good for the fainter stars already mentioned. If it is assumed that the stars of the Pleiades also follow the same law as regards their actual brightness, the distance of the cluster is found to be such that their light takes 600 years to reach us.

From a study of double stars it is found that the stars of the brighter class do not greatly exceed those of the fainter class in mass, and hence that they are either much less dense, or much brighter per unit of surface, or both. The average density of the stars of classes B and A can be found with the aid of certain stars which eclipse one another, and it follows that these stars give off much more light per square mile of surface than the sun does. It can also be shown that the faint red stars give out much less light per square mile than the sun.

If the same is true of the other kind of red stars (which several lines of argument make very probable) these stars must be of enormous size, but very low density.

An arrangement of all these groups of stars in order of increasing density would begin with the bright red stars of the type of Antares, run up the series of stars of great brightness to those of spectrum B, and then down the series of fainter stars, past those like the sun, to the faintest and

reddest stars. It seems probable that this arrangement represents the evolutionary history of a star, which at first becomes heated more and more by its own contraction, and finally, as it becomes too dense to admit of further shrinkage, cools off like a solid body.

At the annual dinner on Saturday evening at the Bellevue-Stratford nearly eighty members and guests were present, the toasts being responded to as follows:

"The Memory of Franklin," by Professor John Bassett Moore.

"Our Sister Societies," by Professor Chas. F. Chandler.

"Our Universities," by Professor Ernest W. Brown.

"The American Philosophical Society," by Professor Francis B. Gummere.

An important feature of this occasion was the presentation of the Henry M. Phillips prize of two thousand dollars to the author of the crowned essay on "The Treaty-making Power of the United States and the Methods of its Enforcement as Affecting the Police Powers of the United States." The successful competitor was Charles H. Burr, Esq., of Philadelphia, the judges of award being Joseph Choate, former ambassador to Great Britain; Judge John C. Gray, of Harvard College; Henry Wade Rogers, dean of the Yale Law School; J. M. Dickinson, former Secretary of War; and Joseph Brown Scott, of the Department of State at Washington.

In their sealed verdict the judges declared that they found great difficulty in deciding the essay of Mr. Burr and that of Edward S. Corwin, of Princeton University.

ARTHUR WILLIS GOODSPEED

SOCIETIES AND ACADEMIES

THE TENNESSEE ACADEMY OF SCIENCE

ON March 9, 1912, a meeting was held in Nashville, Tennessee, to make plans and prepare a constitution for a Tennessee Academy of Science. The meeting was called by Dr. Geo. H. Ashley, then state geologist.

The first general meeting, which was largely attended, was held at the Carnegie Library, Nashville, on April 6, at which time the following officers were elected: C. H. Gordon, president; J. I. D. Hinde, vice-president; Wilbur A. Nelson, secretary, Capitol Annex, Nashville; S. M. Barton, treasurer, and E. S. Reynolds, editor; after which the following papers were read:

"On the Reported Discovery of Radium in Arkansas," A. H. Purdue, former state geologist of Arkansas.

"Neon and Wireless Waves," William L. Dudley, Vanderbilt University.

"Rock Striations and their Causes," Chas. H. Gordon, University of Tennessee.

"Railroad and Road-building in Tennessee before Civil War," Gus Dyer, Vanderbilt University.

"The Beginning of Music," R. M. Ogden, University of Tennessee.

"Food and Drug Inspection in Tennessee," Lucius P. Brown, Tennessee Food and Drug Inspection.

"Review of 'History of Geological Work in Tennessee,'" L. C. Glenn, Vanderbilt University.

"Some Remarkable Phenomena of the Tornado in Montgomery County, Tennessee, April 29, 1909," James A. Lyon, S. P. University.

"Some Effects of Parasitic Fungi on Leaf Tissue," Ernest S. Reynolds, University of Tennessee.

"Photomicrography in Colors by the Lumière Process" (illustrated); "An Apparatus for Washing Fixed Microscopic Material" (illustrated), Samuel M. Bain, University of Tennessee.

"The Selection of Food in Unicellular Animals" (illustrated), Asa A. Schaeffer, University of Tennessee.

"Electrical Conductivity in Dental Fillings," John Daniels, Vanderbilt University.

WILBUR A. NELSON,
Secretary

THE ACADEMY OF SCIENCE OF ST. LOUIS

The meeting of the academy was held at the academy building on Monday, April 1, 1912, at 8 P.M., President Engler in the chair.

Dr. G. O. James, of Washington University, addressed the academy on "The Application of the Relativity of Gravitation to the Motion of the Perihelion of Mercury."

J. L. Van Ornum, professor of civil engineering at Washington University, reviewed the methods practically applicable to prevent dampness in rubble masonry foundation walls; that is, by drainage or by an impervious coating of their exterior, or by both. Impermeability may be attained by constructing an impervious diaphragm of a bituminous material; by an efficient surface coating, preferably on the outside; by carefully securing a maximum density by properly proportioning the components of the concrete; or by mixing with the concrete certain colloidal (or

other) substances to secure this result. The latter two methods have been experimentally investigated in successive years as thesis work by H. F. McFarland, P. C. Grace, S. Johnson and W. K. Bege-man. Their results agree in general with those of others in concluding that, for any usual conditions, the patented mixtures sold for this purpose vary in effectiveness from very poor to very good; and that proper proportioning of the constituents of the concrete to attain a maximum density, such as is desirable to secure a maximum strength, will also effect practical impermeability; but they differ from the conclusions of some others in the fact that they found no advantage to result from the incorporation of such a material as hydrated lime in the richer mixtures.

The apparatus designed by the students for these experiments, which gave pressure up to forty pounds per square inch, was planned to eliminate certain features of the experimental devices of others which seemed objectionable to them; particularly in eliminating tensile stresses from the specimens tested, with the resulting tendency to form cracks.

Professor Nipher gave a preliminary discussion of a phenomenon observed by Planté. It is the buckling of a fine wire through which an electric discharge is passed. Professor Nipher finds that a long and very fine fuse-wire of lead, lying on a strip of glass, usually breaks at the positive end, at a point where it is made fast by sealing wax. The wire at the same time is urged towards the negative terminal, as positive ions are in a gap of air. The metal wire behaves like the positive column in discharge through gases. The negative end of the wire appears to be urged in the opposite direction, as is also the case at the negative terminal in discharge through gases. It sometimes happens that the wire breaks down at the negative end. Nearly all of the wire, however, appears to have the property of the positive column. It is urged longitudinally in a direction opposite to that in which the negative corpuscles are being conducted. Fine copper wire is now being used, and the ends of the wire are left free to move, while the wire is sealed to the glass strip at various intermediate points. The conditions which determine the limiting point between portions of the wire which are being urged in opposite directions have not yet been fully ascertained. The positive ions which constitute the copper wire are not quite as free to "wander" as they are in the case of solutions, or in discharge through gases.

Present indications are that practically all of the fine wire is being urged in a direction opposite to that of the corpuscular flow. There must, however, be an end effect at the negative terminal of the wire which urges the wire in the opposite direction.

At the meeting of the academy held Monday evening, April 15, 1912, Professor A. S. Langsdorf, of Washington University, addressed the Academy on "Transient Electrical Phenomena," Dr. Chas. H. Turner gave an illustrated account of "Results of Recent Experiments on the Homing of Ants," Dr. Arthur E. Bostwick read a paper on "Atomic Theories of Energy" and Professor Wm. H. Roever, of Washington University, exhibited and explained "A Mechanism for Illustrating Lines of Force."

GEORGE T. MOORE,
Corresponding Secretary

THE TORREY BOTANICAL CLUB

The meeting of January 31 was held in the Museum Building of the New York Botanical Garden, Vice-president Barnhart presiding. Twenty-five persons were present. The minutes of the meetings of November 29, 1911, and January 9, 1912, were read and approved. Dr. Marshall A. Howe, chairman of the auditing committee, reported that the committee had examined the books of the treasurer and found them to be correct. The report of the budget committee was presented and approved.

The announced scientific program consisted of the reading of papers on "Sir Joseph Dalton Hooker: His Life and Works," by Dr. N. L. Britton and Dr. J. H. Barnhart. Dr. Britton's paper related chiefly to the life of this distinguished botanist, and his publications relating to botany were discussed by Dr. Barnhart. As Sir Joseph Hooker was an honorary member of the Torrey Club, Dr. Barnhart took this occasion to bring before the club the constitutional provisions relating to honorary membership and read the list of all persons who have been elected to honorary membership.

Mr. Fred J. Seaver spoke briefly on the viability of the spores in *Pyronema*. While *Pyronema* has been made the subject of numerous research papers and is figured and treated in most of the recent text-books of general botany, it still remains an unknown plant to most botanists, except to the few who have done critical work with it. There is

no reason for it being so, for the fungus is fairly common and is easily grown, as has already been shown in previously published papers. In a recent experiment the speaker was able to show that the spores of this fungus which had been kept nearly three years in the herbarium germinated readily in hanging-drop culture. This last point should be of general interest to teachers of botany, since it means that the plant can be grown and studied from living material and the old plants then placed in an envelope and kept until the next year, when they can be planted and grown again. No complicated technique is necessary for the growing of *Pyronema*. A pot of garden soil should be heated. Heating can be carried on in an autoclave or sterilizing oven. If these are not to be had bake in an ordinary oven. Saturate the soil with tap water after heating and plant the spores. Growth of mycelium should be abundant in two or three days, sex organs should appear in about a week, and mature ascocarps a few days later. A more detailed account of this subject will appear in the *Bulletin* of the club.

Dr. Marshall A. Howe spoke briefly on "Some Marine Algae from the Stomach of a Peruvian Green Turtle" and exhibited specimens from the source indicated, collected in Peru by Dr. Robert E. Coker. The fragments were in a good state of preservation and two of the species concerned are readily determinable, the most abundant being *Rhodymnia flabellifolia*, a common Peruvian and Chilean species and a close relative of the edible "dulse." The alga coming next in point of abundance is *Caulerpa flagelliform lingulata*, a species occurring elsewhere in Dr. Coker's Peruvian collections, but not before reported from the shores of the American continent. Fragments of a species of *Gelidium* not so certainly determinable also occur.

Dr. W. A. Murrill gave a short account of the progress of his studies on the Agaricaceae of tropical North America and also read some mycological notes relating to the Washington meeting.

The meeting of February 13 was held at the American Museum of Natural History at 8:15 P.M. Twenty-three persons were present.

The announced scientific program consisted of a lecture on "Some Botanical Features of a Desert Mountain Range," by Dr. Forrest Shreve. The lecture was illustrated with lantern slides.

B. O. DODGE,
Secretary

BOLOGNA and Paris are the archetypal universities from which all others have descended and from which they have in some measure inherited their present organization and methods. In the first decades of the twelfth century Irnerius lectured at Bologna on the civil law, and Abelard at Paris on philosophy and theology. There were at the same time other eminent teachers in those cities, and students were attracted from all parts of Europe. The students in a foreign city organized themselves into guilds for mutual protection and assistance in accordance with the custom of the time. These were the first universities. The lecturers, who had previously taught as the sophists at Athens and the rhetoricians at Rome, or as masters of music, dancing and gymnastics teach to-day, also organized themselves into societies or universities. There were no endowments; no academic buildings. The professors lectured at their homes or in

¹This paper, more especially the collection of letters from university professors, was prepared for the faculties of the University of Illinois, and for discussion before their committee charged with drawing up a constitution for the university. Papers on the subject have also been presented before the Society of Sigma Xi of the University of Indiana, the Huxley Club of the Johns Hopkins University and at a joint meeting of the faculties of Lehigh University and Lafayette College. The fact that in the last two cases the presentation was in the form of an after-dinner address may account for the more frivolous and rhetorical passages, and for the use of the first personal pronoun. These might have been eliminated—they have been reduced—but a reformer should be concerned with accomplishing his ends rather than with conserving his dignity.

hired houses; the academic convocations were held in churches or monasteries. When there were difficulties with the city authorities or with their colleagues, a group of professors or students might migrate and found a new studium elsewhere. Thus in the thirteenth century offshoots from Bologna gave rise to studia at Reggio, Vicenza Arezzo, Padua, Vercelli and Siena. Oxford, the third of the great medieval universities, was probably due to a migration from Paris in 1167.

At Bologna the universities of students—who were men of maturity from all parts of Europe, as many as ten thousand at the end of the twelfth century, it is said—obtained control, lording it over the professors by means of the boycott. At Paris the students, organized into nations, were somewhat younger, and the professors, doctors or masters, as they were indifferently named, were in control. In one respect the conditions were curiously similar to the contemporary American university, for there was a college of arts of younger students, and professional schools of theology, law and medicine. We even read of an anticipation of present tendencies in that students had to receive the degree in arts before entering the medical school. About the middle of the thirteenth century there were established colleges of residence which were endowed as eleemosynary institutions for poor students, usually under the control of the church. In England the colleges were the property of the head and fellows, who had complete control of the establishment; on the continent they were somewhat less independent. In the course of time the differences became emphasized. The continental colleges became absorbed in the university and disappeared as halls of residence, whereas at Oxford and Cambridge the colleges practically constituted the university.

It is truly remarkable that there should have been some seventy-five universities throughout Europe before the time of the invention of the printing press and amid the incessant warfare of those days. One may wonder whether love of learning was not greater, intellectual curiosity keener, then than now. The students, numbered by the thousand—legend puts it as high as 30,000—flocked to a university attracted by the reputation of a great teacher. The rich came with their retinues, while the poor begged their way. Irnerius at Bologna, Roscellinus and Abelard at Paris, Grossetête and Roger Bacon at Oxford, were followed by long lines of great men, teachers, scholars, founders of science.

My main concern with the medieval university is that it was extraordinarily unhierarchical, democratic, anarchic, in its organization. The university was then, as it now should be, the professors and the students. The professors, of course, had complete control of the conditions under which degrees were given and in the selection of their colleagues and successors. The doctor earned the *jus ubique docendi*; he was not employed or dismissed. There was an elected council and rectors were elected for a year or for some other short period. Only later there came to be a single rector for the entire studium. The whole paraphernalia of the modern university—endowments, buildings and grounds, trustees and president, heads of departments and deans, curricula, grades and examinations—were absent or subordinated. There were indeed all sorts of routine, customs and limitations, but the university, in an age of feudalism and of absolutism of state and church, attained a remarkable freedom, and its great performance was in large measure due to this freedom.

It further seems to be the case that the waning of the influence of the university

in the course of time was largely due to the loss of freedom. As the universities obtained endowments and buildings, as their governing bodies became organized, they lost their spontaneity and creative leadership. The great philosophers, scholars and men of science of the seventeenth and eighteenth centuries worked in large measure outside the universities. Bacon, Hobbes, Locke and Berkeley; Descartes, Spinoza and Leibnitz; Harvey, Huygens and Laplace; Linnæus, Buffon, Lamarck and Cuvier; Lavoisier, Priestley and Dalton, were not university professors or not primarily such. Newton was, but he relinquished his chair at Cambridge to take a position in the mint at London. The men of science of the seventeenth and eighteenth centuries worked largely in connection with the academies of science, which were then established, and in the newly founded museums, observatories and botanical gardens. This movement is analogous to the contemporary establishment of research institutions outside the universities. There was too much dogmatism, formalism, discipline, routine, control, machinery—it might have been called efficiency if they had had the word in those days—in the university, and scientific men found greater freedom and stimulus in the academies, which, though under the patronage of the court, they themselves controlled.

Toward the close of the eighteenth century the universities throughout Europe had sunk to a low level. Within a period of a few years as many as thirteen German universities became extinct—Mainz, Cologne, Bamberg, Dillingham, Duisberg, Rinteln, Helmstedt, Salzburg, Erfurt, Altdorf, Frankfort, Ingolstadt and Wittenberg. But the new era of freedom and democracy, represented and caricatured by the French revolution, gave fresh life to the universities. The centralized scheme

of Napoleon aggrandized Paris at the cost of the provincial universities, which only just now are regaining their autonomy. In Germany the modern university attained its fruition. The University of Berlin, established in 1809, when the political fortunes of Prussia were at low ebb, played a great part in the regeneration of the nation. It was partly founded on the basis of the existing Academy of Science, as was the University of Munich a little later. It is possible that our newer research institutions, if placed under the control of men of science, may become the freer universities of the future.

During the nineteenth century the German universities rivaled in their influence those of the medieval period. The advances of democracy and of science have been the great achievements of our era. In the advancement of science and to a certain extent in the maintenance of a democracy of scholarship, the German universities have been dominant forces. In Germany the university is indeed the creature of the state and subject to it. But during the nineteenth century academic freedom and the independence and influence of the professor attained a remarkable supremacy. Any student who showed ability could become a *Privatdozent*; if he continued to advance his subject with sufficient distinction and did not starve to death in the meanwhile he became a professor. The professorship has been maintained as a position of dignity, honor and freedom. The professor receives his appointment by the decision of his peers and holds it for life. He may lecture about as much or as little as he likes, on almost any subject, well or poorly as the case may be, with complete freedom in the expression of his views; he is but little concerned with grades, absences, discipline, routine reports, committee meetings and the like; he gives

much or little attention to his students as he may choose. The rector is elected annually by the professors. The curator, the representative of the government, the efficient man who runs things, is nowhere regarded as the intellectual or social equal of the professors.

All this might be supposed to lead to abuses; but the result is there to be seen by every one—the great scholars and men of science; the contribution to national progress and the civilization of the world. No efficient machine driven by the president of an American university can grind out such flour. I fear that the German university can not continue its great performance of the nineteenth century. This was doubtless more the result than the cause of the idealism of the people, now threatened with submergence under wealth and luxury. The modern German university must have its fine buildings, must grow greatly in size. This is inevitable, perhaps desirable. Laboratories, libraries and collections are required on a scale not formerly imagined; there is danger, perhaps need, of more administrative machinery, and the more machinery you have, the more you must get. It seems that the professors now tend to form a bureaucratic guild, too greatly concerned with their own financial status, and too little with the welfare of the docents and associate professors, of the students and of the people. The Prussian ministry is interfering more than formerly in the selection of professors and the management of things. The German emperor, it is said, wants presidents in the American style—we could spare him at least one for each of the twenty-one German universities.

It seems remarkable that in the bureaucratic little states which have since become the German empire, the universities should have been centers of liberal scholarship and free personalities. But it is perhaps gen-

erally the case that the finest exhibitions of the love of liberty and honor are made under persecution or where there are contrasted conditions. It is really quite difficult and discouraging to play the part of an academic hero or martyr now-a-days. One can do it better in Russia than in the United States. Thus a hundred professors at Moscow have recently resigned owing to some interference of the government with the liberty of the professors. In that country students and professors strike, and the government institutes lockouts. They take their liberties seriously, and the professors maintain their right to choose their colleagues and their deans and rectors.

The historic English universities, Oxford and Cambridge, have been primarily groups of independent colleges. The master and fellows are the college; they own the buildings and endowment and divide the income among themselves. They elect their colleagues and successors and of course their head. The headship is an honorary and social position with but few executive powers or duties. Government is by town meeting and committee. There have been abuses of the monastic system, and perhaps even now too much time is spent on details of management. But high standards of scholarship and conduct have on the whole been maintained. From among their resident fellows and from their students great men have been forthcoming in every line of activity. Probably half the leaders of England in statesmanship, scholarship, science, poetry, have come from its two universities, having together no more students than one of our larger institutions; and England has produced more great men than any other nation.

The universities of Oxford and Cambridge, as distinguished from their colleges, have long had a few endowed professorships and conducted libraries, but until

recently they were essentially degree-conferring institutions. They are administered by councils elected by the resident teachers, but the ultimate control is vested, as is becoming, in the masters of arts. The Church of England clergy have perhaps had more influence than is desirable, but their interference has in the main been confined to prescribing the conditions for the degree. In any case it is only a temporary phase, and a certain amount of conservatism is not so bad for a university. It would seem quite absurd to invest the ultimate control of Oxford and Cambridge in a self-perpetuating board, consisting of a score or larger crowd of business and professional men. The chancellorship is an honorary office, without executive power or influence, to which a non-resident graduate of distinction is elected. With the specialization of knowledge and the need of laboratories, the colleges could not give all the instruction needed, and the universities of Oxford and Cambridge are becoming increasingly teaching bodies. Parliament has required the colleges to give some part of their income to the support of the university. The professors are usually nominated by boards of electors, consisting of men of distinction in the subject or in related subjects, partly from the university and partly from outside. I have never heard of the expulsion of a fellow or professor. That a professor's salary should depend on the favor of a president or that he should be dismissed without a hearing by a president with the consent of an absentee board of trustees is a state of affairs not conceivable in an English or German university.

Harvard College was founded in 1636 by the general court of the Colony of Massachusetts Bay and placed under a board of overseers named by the court. In 1650 there was established a self-perpetuating

corporation consisting of a president, a bursar and five fellows, which, however, was made responsible to the overseers. In 1865 the election of overseers was transferred from the legislature to the alumni of the college. The Collegiate School of Connecticut, subsequently named Yale College, was chartered by the legislature of the Colony of Connecticut in 1701 and placed under the control of trustees or partners, consisting of ten reverend ministers of the gospel. In 1745 the corporation received the title of The President and Fellows of Yale College. Later the governor, the lieutenant governor and six senators of the state were added to the fellows; in 1872 alumni trustees were substituted for the senators. The College of William and Mary was chartered in 1693 by the sovereigns whose names it bears. Princeton, Pennsylvania and Columbia, chartered, respectively, in 1746, 1751 and 1754, were placed under the control of boards of trustees, and, like Harvard and Yale, either at their inception or later, were controlled by the state and received appropriations from it. In my opinion it would have been better if the relation between the state and its university had been maintained.

The colonial college was largely modeled on the Cambridge college; thus the form of the Harvard and Yale corporations—the president and fellows—was directly borrowed. At Harvard the corporation included the teachers of the college; there was much protest the first time an alumnus was elected a fellow when there was a tutor eligible. It would be interesting to trace—did time and my competence permit—the steps through which our colleges slipped from the control of the state and of the graduates and teachers into the hands of small self-perpetuating corporations, until we reach the most reactionary

of all charters, that of 1810 for Columbia College, the provisions of which are as follows:

The said trustees, and their successors, shall forever hereafter have full power and authority to direct and prescribe the course of study and the discipline to be observed in the said college, and also to select and appoint by ballot or otherwise, a president of the said college, who shall hold his office during good behaviour; and such professor or professors, tutor or tutors, to assist the president in the government and education of the students belonging to the said college, and such other officer or officers, as to the said trustees shall seem meet, all of whom shall hold their offices during the pleasure of the trustees. *Provided always*, That no such professor, tutor, or other assistant officer shall be a trustee.

The careers of our colleges were checked by political and church dissensions; thus, in the case of Columbia, the subordination of the professors is in part explained by distrust of their episcopalian tendencies. It seems that the organization of our colleges was influenced not only by the college of the English universities, but also by the English endowed public school, to which it came to bear a greater resemblance.

The University of Virginia was established as a state institution by the legislature in 1819. Under the influence of Jefferson the continental university was to a certain extent followed; and both in educational and administrative methods there was much that was admirable—at least from my point of view. Under the general control of a board, the affairs of the university were administered by the faculty and its elected chairman, until after eighty years souls were once more sold for gold. The University of Indiana was established in 1820, the University of Michigan in 1837, as part of the public educational system of those states, the governing bodies being elected boards. Here was inaugurated a new movement in higher educa-

tion, destined, I trust, to parallel the great performance of the medieval university and of the German university. The institutions of the Atlantic seaboard having slid into capitalistic control, there has arisen in the central west a system of higher education directly responsive to the will of the people on whose support it depends.

Prior to the last quarter of the nineteenth century, we had colleges and professional schools, but no university. Yale, it is true, first offered the doctorate of philosophy in 1860, and in the early seventies the degree was given by Harvard, Columbia and Cornell. But the graduate work of a faculty of philosophy was not organized or emphasized until the opening of the Johns Hopkins University in 1876, when there arose an institution nearer to my conception of what a university should be than any elsewhere in this country or than it has been able to remain. Buildings, administration and routine instruction were subordinated to great men who attracted from the whole country the students who were to be the future leaders. In the organization of the Johns Hopkins Medical School in 1893 a contribution of nearly equal significance was made in placing the professional school on a university basis. The past two or three decades have witnessed an almost incredible growth of our universities. Columbia has now 700 instructors, 7,000 students, fifty million dollars. In spite of the materialistic standards and autocratic methods of control which this paper emphasizes—perhaps overemphasizes with a view to their correction—the development of the American university, especially of the state university, is one of the greatest achievements of our people, promising moral, social and intellectual leadership and supremacy in the course of the present century.

If here or elsewhere I have expressed

opinions which seem lacking in appreciation of what is being accomplished in this country for higher education and for the advancement of science, this is only because it is not possible to put in each paragraph or even in a single paper everything that one believes. The most useful forward movements and the greatest men are subject to just criticism. It is only when the work has been accomplished and the men are dead that we may forget the faltering and the errors and eulogize the good that has been done. In our educational and scientific work, as in our business, social and political life, we must oppose with all our power the materialistic aims and autocratic usurpations which are the not unnatural accompaniments of the development of the vast resources of a new country and the passing from aristocratic to democratic control. As I wrote² before the present democratic movement had gathered its existing force:

The applications of science—which in the first instance made democracy possible by supplying the means of subsistence with possible leisure and education for all—have in their recent developments enormously complicated modern civilization. Our methods of communication, transport and trade, of manufacture, mining and farming, have led to the doing of things on an immense scale. The individual has once more been subordinated, crudely commercial standards prevail, and control has been seized by the strong and the unscrupulous. Those of us who are not ashamed to profess faith in democracy regard all this as a temporary phase, which will only last until intelligence has developed equal to the complexity of the environment. The only real danger is that instincts may become atrophied before reason is ready to take their place.

The trust promoter and insurance president, the political boss and government official, the university president and school superintendent, have assumed powers and perquisites utterly subversive of a true democracy. The bureaucracy is defended on the ground of efficiency; but efficiency is not a

² "The University and Business Methods," *The Independent*, December 28, 1905.

final cause. To do things is not a merit regardless of what they are, and bigness is not synonymous with greatness. There is no ground for hopelessness. Of the things done the good may last and the rest may be eliminated; bigness may become greatness. The organizers of our huge corporations have in a way made history prematurely; these vast combinations were inevitable; the trouble is that they have come before we are ready to manage them. We have no evidence that people are less competent, honest and kindly than they were; it is the difficulties and the temptations that have increased.

There is ground for maintaining that the methods of the business corporation and the political machine have been somewhat wantonly applied to educational administration in this country. On the one hand, educational institutions are not and need not become so big and complex as to require the sacrifice of freedom to supposed efficiency, and, on the other hand, those who are the university—the teachers and the students who are or have been under their influence—have far more than average intelligence. . . .

In stating frankly views that are shared by a larger proportion of my colleagues than is generally supposed, I by no means wish to adopt the attitude of a pessimist. I know well from personal experience with what unfailing courtesy and ceaseless effort a university president may conduct the affairs of his difficult office. Much has been accomplished for higher education in the United States. As the industrial trusts will in the end be directed by the world's greatest democracy for the benefit of the people, so our educational system may give the material basis for an efflorescence of creative scholarship springing from a free and noble life.

My own academic experience has been mainly in the endowed institutions of the Atlantic seaboard. My father was president of Lafayette College from 1863 to 1883, during which period the teachers increased from nine to thirty, the students from 60 to 300, and the property from \$50,000 to \$1,000,000. There the personal and patriarchal system of college control was exhibited at its best. It doubtless now flourishes in many small institutions throughout the country as in the English public schools. A man such as Mark Hop-

kings or Thomas Arnold has been the soul of the institution. As Matthew Arnold writes in "Rugby Chapel"

... to thee was it given
Many to save with thyself;
And, at the end of thy day,
O faithful shepherd! to come,
Bringing thy sheep in thy hand.

As a fellow at the Johns Hopkins University at the zenith of its great achievement, I had again opportunity to witness the system of presidential autocracy under favorable conditions. The university was dominated by one man who was personally responsible for and to its dozen professors and two hundred students. But the patriarchal system is of necessity limited to the small institution, and it is scarcely fitted to the democracy of the twentieth century. In a residence of six years at European universities, I had experience of the educational system, but though I was assistant at the University of Leipzig and lecturer at the University of Cambridge, I was at that time indifferent to administrative methods. These have been increasingly forced on my attention since my appointment as professor at the University of Pennsylvania and lecturer at Bryn Mawr College, and for the twenty years during which I have been professor at Columbia University.

I reviewed the problems of university control in a short article printed in *SCIENCE* some six years ago. This was reprinted with certain added footnotes, and at the beginning of December sent to our leading men of science, who hold or have held academic positions, with the following note:

Would you be willing to give your opinion of the plan of university control here proposed? If you are so kind as to do so, I shall understand that I may quote anonymously your reply.

About 300 replies have been received, which are printed practically in full as an

appendix to this paper. The article on which the replies were based is as follows:

UNIVERSITY CONTROL*

In the colleges from which our universities have developed the problem of administration was comparatively simple. The faculty and the president met weekly and consulted daily; each was familiar with the work of the entire institution; a spirit of cooperation and loyalty naturally prevailed. The trustees also understood the economy of the college and were able to work intelligently for the general good. But when a university covers the whole field of human knowledge, when it is concerned with professional work in divergent directions, when it adds research and creative scholarship to instruction, when both men and women are admitted, when there are 500 instructors and 5,000 students, it is no longer possible for each trustee and for each professor to share intelligently in the conduct of the whole institution. We appear at present to be between the Scylla of presidential autocracy and the Charybdis of faculty and trustee incompetence. The more incompetent the faculties become, the greater is the need for executive autocracy, and the greater the autocracy of the president, the more incompetent do the faculties become. Under these conditions it appears that the university must be completely reorganized on a representative basis. It should not be a despotism and it can not be a simple democracy. Autonomy should be given to the schools, departments or divisions. The administrative, legislative and judicial work must be done by experts, but they should represent those whom they serve. . . .

The present writer ventures to propose tentatively the following form of organization for our larger universities, to be reached as the result of a gradual evolution:†

* Reprinted from *SCIENCE*, for March 23, 1906, with footnotes added in November, 1911.

† No sensible person would attempt to reform suddenly by a paper constitution a system which has developed in response to its environment. The boss in politics, the trust magnate in business, the university president and school superintendent, have probably conduced to a certain kind of efficiency and to an enlargement more rapid than would otherwise have been possible. What a community does is dependent on the men who compose it rather than on the laws under which they live. But a bad system may demoralize the cooperative spirit of the group and may select for it individuals who are not the most desirable. The danger of our present system of university control is that

1. There should be a corporation consisting of the professors and other officers of the university, the alumni who maintain their interest in the institution and members of the community who ally themselves with it.⁸ In the case of the state universities part of the corporation would be elected by the people. This corporation should elect trustees having the ordinary functions of trustees—the care of the property and the representation of the common sense of the corporation and of the community in university policy.⁹ The trustees should elect a chancellor⁷ and a treasurer who would represent the university in its relations with the community.

2. The professors or officers, or their representatives, should elect a president who has expert knowledge of education and of university administration. His salary should not be larger, his it tempts a man to play for his own hand and selects for academic work men lacking in character, individuality and genius.

⁸ A large corporation of this character places the ultimate control on a democratic basis. The members would pay annual dues, and a considerable income would thus accrue. A large number of individuals would take an active interest in the welfare and development of the institution. In the case of the state universities the people of the state are in a sense the corporation with ultimate control, and it might be undesirable to establish an intermediate body. Still the state might delegate its powers to such a corporation, and a society of members of the university might be formed, even though the regents or trustees were elected by the people or appointed by their elected governors.

⁹ The trustees or regents of an American university have absolute powers, but tend to delegate them to the president. They place a limit on the amount of money that can be spent and sometimes use their reserve powers even in matters of educational detail. When the corporation is small, as at Harvard, it may be in active control of policies. In the private chartered institutions it is usually large, its members having but little knowledge of educational problems or of the special university under their control. There are often several trustees who take an active, though not always a wise, interest in the university, and it is a delicate problem of the president to manage such trustees. One of the most serious difficulties of the present situation is that the president owes his office, salary and powers to the trustees and must obtain their favor, whereas he is not responsible to the faculties. The professor is likely to owe his office and salary to the president, and is sometimes placed in a position that is humiliating.

⁷ It might or might not be an advantage to have a chancellor, such as exists in the British universities, a man of prominence in the community, who would obtain endowments and represent the university at public functions.

position more dignified or his powers greater than those of the professor.⁶

3. The unit of organization within the university should be the school, division or department, a group of men having common objects and interests, who can meet frequently and see each other daily. It should be large enough to meet for deliberation and to represent diverse points of view, but small enough for each to understand the whole and to feel responsible for it. The size of this group is prescribed by a psychological constant, its efficient maximum being about twenty men and its minimum about ten.⁹

4. Each school, division or department should elect its dean or chairman and its executive committee, and have as complete autonomy as is consistent with the welfare of the university as a whole.¹⁰ It should elect its minor officers and nominate its professors. The nominations for pro-

⁶ It may be that no president is desirable other than an annually elected rector, as in the German universities. If, however, the president were elected by the faculties for a limited term and made responsible to them, the academic situation would be greatly improved. The argument of efficiency can be adduced in favor of giving autocratic powers to one individual, but the university is the last place where such system should prevail. It is neither necessary nor desirable that things be done in haste. Administrative details can be handled promptly by a clerk or secretary. Men and women should not be subject to the judgment or whims of an individual. Security, permanence, honor, the slow growth of traditions, are essential to a true university.

⁹ Such autonomy is usually possessed by medical, law and technical schools forming a part of a university. It should be extended to other divisions when they become sufficiently large. Partly independent institutions for teaching or research can to advantage form part of a university. The separately endowed colleges of the English universities have certain advantages.

¹⁰ In the department-store system, which is likely to prevail in our universities, the junior professors and instructors are responsible to the head of the department and are dependent on him for advances in office and salary, while the heads of departments are in like position in relation to the dean or the president, the heads of departments and deans being named by the president. The active committees are appointed by the president; in one of our leading universities even faculty members are named by the president from among the professors, making the faculty a presidential committee. This procedure reverses the proper or, at all events, the democratic method of control, according to which officers are chosen by those whom they serve and leaders are followed because they are acknowledged as such.

fessorships should be subject to the approval of a board of advisers constituted for each department, consisting, say, of two members of the department, two experts in the subject outside the university and two professors from related departments. The final election should be by a university senate, subject to the veto of the trustees. The same salaries should be paid for the same office and the same amount of work. The election should be for life, except in the case of impeachment after trial." The division should have financial as well as educational autonomy. Its income should be held as a trust fund and it should be encouraged to increase this fund.

5. The departments or divisions should elect representatives for such committees as are needed when they have common interests, and to a senate which should legislate for the university as a whole and be a body coordinate with the trustees. It should have an executive committee which would meet with a similar committee of the trustees. There should also on special occasions be plenums of divisions having interests in common and plenums of all the professors or officers of the university." There should be as much flexibility and as complete anarchy throughout the university as is consistent with unity and order.

It seems that the 299 replies expressing the opinion of the writers on this paper

"The greatest possible care should be exercised in the selection of professors. Instructors and lecturers should be freely admitted to the university, but the professorship should be maintained as a high office. The alternative to permanence of tenure is competition for prizes under honorable conditions, but in this case salaries must be as large as the incomes of leaders in law, medicine and engineering. It is more economical and probably conduces to greater dignity and honor to pay adequate but moderate salaries with permanence of tenure, as in the army or the supreme court. Advances in salary should be automatic, as at Harvard, but there might to advantage be a few professorships with comparatively high salaries—the same as that of the presidency—vacancies in which would be filled by cooptation or by election by the faculties.

"Professors and other officers should not be distracted from their work of teaching and research by administrative politics. But they should select their administrative officers and legislative committees and have opportunity to make proposals and vote on questions of educational policy. Voting by mail and the fly-leaf method of discussion of the English universities could be adopted to advantage. An elected executive committee of the faculties meeting with the executive committee of the trustees is a feasible method of improving the existing academic situation.

represent with considerable accuracy the existing academic sentiment in this country among those who have been most successful in their work. They are all from men in the natural and exact sciences, who form somewhat less than half our university professors, but there is no reason to suppose that their colleagues in other departments would differ as a class in their attitude on academic questions. I wrote to scientific men because I had a list of those of highest standing and am personally acquainted with most of them. It may be that in some cases men were more likely to reply because they agreed with my views and were more likely to emphasize their agreement than their dissent. As a psychologist by trade, I judge, however, that this is more than balanced by the opposite tendency to react by objecting and to argue against a proposition proposed. Probably the replies of younger men and of less successful men would be more radical and more opposed to the existing system of university control.

The letters are well worth a careful reading. We are told that every question has two sides; as a matter of fact many questions are polygons. The problems of the administration of an educational institution have many sides and many angles. They differ completely in the small college and in the large university, in the newer and in the older institutions, in the state university and in the private corporation. My paper was written with reference to the large endowed universities, especially those which have enjoyed or suffered a rapid growth in size and scope. The replies are from institutions of all kinds. Those who hold chairs in the smaller colleges may find a system fairly adequate to their needs which would be undesirable in our large universities. Those in state universities may regard as

necessary a strong executive responsible to the people and professors subordinated to the public service, when they would not approve of the irresponsible autoocracy of the private corporations. Professors at Harvard and Yale may take satisfaction in the long traditions and wise precedents which obtain at these universities, when they would not care to live under the system in use at Columbia and Chicago.

It was originally my intention to base this paper on an analysis of the letters received, but the exigencies of an engagement made it necessary to prepare its first version before the proofs could be obtained, the letters written and the replies received. It is indeed somewhat difficult to summarize such a large number of points of view which represent both real differences of opinion and differences due to the fact that various situations were under consideration. It seems best to print the letters, and to permit those interested to draw their own conclusions. The letters will be given under the institution from which they come when there are as many as ten replies, the institutions otherwise being grouped. In general, the letters are placed in the order of their preference for the existing system of university control which I designate as a limited autoocracy. Omissions have been made from some of the longer letters and, formal compliments, apologies and the like have been erased. Thus a large percentage of all letters begin with the phrase "I have read with interest," etc. Other slight editorial revision, such as eliminating the paragraphs, has been undertaken, but every effort has been made not to alter in the slightest degree the opinions expressed. There is given here a table showing the source of the replies and the only classification that I shall attempt to make. Its validity can be

judged by those who care to read the letters.

	Limited Auto- cracy Present System	Greater Faculty Control	Representative Democ- racy; Plan Proposed	Total
Harvard	9	6	11	26
Yale	1	6	4	11
Columbia	2	2	10	14
Pennsylvania	0	3	9	12
Johns Hopkins	0	2	14	16
Chicago	1	0	17	18
Cornell	0	4	8	12

C. & W. State	2	7	14	23
C. & W. Private	7	7	16	30
Anonymous	0	1	2	3
Total	46	69	184	299

Of the 299 replies 46 are taken as favoring the system usual in this country, which is designated as a limited autoocracy, 69 as favoring a system in which the faculties have greater share in control, as at Yale or the Johns Hopkins Medical School, 184 as favoring a plan of representative democracy more or less similar to the one proposed. Five sixths of those holding the most important scientific chairs at our universities believe that there should be a change in administrative methods in the direction of limiting the powers of the president and other executive officers and making them responsible to those engaged in the work of teaching and research. This is an agreement greater than I had anticipated. When eighty-five per cent. of those responsible for the conduct of a given system unite in holding that it should be altered, the case may be regarded as strong. Political and social changes are usually made on a much narrower majority. It is true that five of the six presidents who replied—they are of course

at the same time men who formerly did distinguished scientific work—form part of the minority. Indeed, a large percentage of this minority consists of presidents, directors, deans and other university officials.¹³ Whether this should be interpreted as that much in favor of the present system, or that much more against it, may be left an open question.

A considerable number of professors at Harvard favor the existing system, but their preference applies to their own situation, where the administrative autocracy is tempered. Of 19 replies from Wisconsin and Illinois, eight favor a limited autocracy, but they have in mind their system, which is not the same as that of the private universities. Probably they would in any case prefer the methods of President Van Hise and President James to those of President Draper. Those who want a strong executive responsible to the people of the state have been classed in the group favoring a limited autocracy. Thus the two replies from Columbia which are placed in this group are from men who do not trust faculty control, though, as I happen to know, they are by no means satisfied with the existing situation. If these two cases are omitted, we find that of 70 replies from Columbia, Pennsylvania, Cornell, Johns Hopkins and Chicago—these are the institutions which I had especially in mind in my proposals—only one (an executive officer) favors the existing system, eleven favor greater faculty control, and 58 a

¹³ Eighteen of the replies are from men who formerly held academic positions but are now connected with research institutions, the government service, etc., or who while holding professorships are principally engaged in other work. These replies show about the same distribution as the others, three in the first group, four in the second and eleven in the third. They are classed under the institutions with which the men are or were connected. Two replies from those previously connected with universities as teachers, but somewhat incidentally, have been omitted. They both belong to the third group.

complete change which would make the administration responsible to the faculties. This is surely a condition which foretells reform or bankruptcy.

J. McKEEN CATTELL
(To be continued)

ABBOTT LAWRENCE ROTCH

ABBOTT LAWRENCE ROTCH was born in Boston, January 6, 1861, the son of Benjamin Smith and Anna Bigelow (Lawrence) Rotch. He was graduated from the Massachusetts Institute of Technology (S.B.) in 1884. In 1891 Harvard recognized the importance of the work which he had already accomplished by bestowing upon him the honorary degree of A.M. From 1888 to 1891, and again from 1902 to 1906, he held the appointment of assistant in meteorology at Harvard, a position which involved no teaching and in which no salary was paid. In 1906 he was appointed professor of meteorology, an honor which he prized very highly, and which gave him the position on the teaching staff of the university to which he was in every way fully entitled. He was the first professor of meteorology who has occupied that position at Harvard, and he served in this professorship without pay. In the year 1908-09, at the request of the department of geology and geography, he generously put the splendid instrumental equipment and library of Blue Hill Observatory at the service of the university, by offering a research course ("Geology 20f") to students who were competent to carry on investigations in advanced meteorology. This action on the part of Professor Rotch gave Harvard a position wholly unique among the universities of the United States. It brought about a close affiliation, for purposes of instruction and of research, between the university and one of the best-equipped meteorological observatories in the world. To his work as instructor Professor Rotch gladly gave of his time and of his means. He fully realized the unusual ad-

¹ An appreciation of Professor A. Lawrence Rotch, based on the same material, appears also in the *Harvard Graduates' Magazine*.—R. DeC. W.

vantages which he was thus enabled to offer those students who were devoting themselves to the science of meteorology, and the experience of the men who had the privilege of his advice and help in the work at Blue Hill shows clearly how much they profited by this opportunity. Only a short time before his death he had expressed the wish to bring about a still closer connection, for purposes of instruction, between the university and Blue Hill Observatory. He thus showed his appreciation of the importance of the new field of work which he had undertaken.

While thus planning still further usefulness for his observatory; in the midst of a life singularly active; with an ever-widening sphere of scientific influence and a constantly increasing importance of his contributions to meteorology, Professor Rotch died suddenly in Boston on April 7, 1912, in the fifty-second year of his age. His wife, who was Miss Margaret Randolph Anderson, of Savannah, Ga., and three children survive him.

Professor Rotch early developed that absorbing interest in meteorology which caused him to devote his life to the advancement of that science. Possessed of large means, he preferred to work persistently, and not infrequently to undergo discomfort and hardship in his chosen field of research, rather than to live a life of ease. Realizing the need of an institution which could be devoted to the collection of meteorological observations, and to meteorological research, free from any entanglements, he established, in 1885, Blue Hill Observatory. This was first occupied by Mr. Rotch and his observer, Mr. W. P. Gerrish, on February 1, 1885. This observatory he not only equipped and maintained until his death, but he made provision in his will for having the work there carried on without a break. Blue Hill Observatory is to-day one of the few private meteorological observatories in the world, and there is not one which is better equipped. In fact, it is probably safe to say that there is no private scientific establishment which is better known for the high standard of its work. The Blue Hill Observatory was, with the exception of

the municipal meteorological station in New York, the first in this country to be equipped with self-recording instruments, and it is to-day one of the comparatively few in the world where nearly every meteorological element is continuously recorded. Beginning with 1886, hourly values have been printed. Professor Rotch took a splendid pride in his observatory, and in its equipment, and his library, to which he devoted constant care, was one of the most complete and valuable in the world.

Professor Rotch early realized that the advance of meteorology must come through a study of the free air, and with keen and prophetic judgment he planned and carried out the remarkable series of investigations which have made Blue Hill so famous. He secured assistants who were well fitted to carry out the researches which he planned and supervised. He thus showed his ability to judge the value of men, as well as his capacity to organize the work for them to do. Mr. H. H. Clayton became a member of the Observatory staff in 1886, and served, as observer and meteorologist, with some interruptions, for twenty-three years. His work brought distinction to himself and to the observatory. Mr. S. P. Ferguson joined the staff in 1887, and remained there until 1910. Many new instruments were devised by him, and perfected with care and success. Mr. A. E. Sweetland died after eight years of service and was succeeded, in 1903, by Mr. L. A. Wells, who is now observer-in-charge, with Mr. A. H. Palmer as research-assistant. Year after year the Blue Hill publications have contained results of far-reaching importance. It is not an exaggeration to say that much of the recent rapid advance of meteorological science is due to the pioneer work which was done at Blue Hill.

Under an arrangement entered into between Blue Hill Observatory and the Astronomical Observatory of Harvard College, Professor Rotch was, for nearly twenty-five years, closely associated with the latter institution. All of the observations made at Blue Hill were published in the *Annals* of the Harvard Observatory, and fill eight quarto volumes.

The international form of publication, and metric units, were first used in the United States in the publications of the Blue Hill Observatory.

It was one of Professor Rotch's most striking characteristics that he never neglected any opportunity which might help him to keep his observatory not only abreast of the times but ahead of the times. He thought nothing of the time and the expense of taking a trip to Europe in order to attend some scientific meeting, meteorological or aeronautical, if he believed, as he most firmly did, that he might by so doing gain inspiration and new ideas. Few scientific men are so regular in their attendance at congresses and meetings; few contribute so much that is new or gain as much inspiration as he did at such gatherings. It was not the blind following of the dictates of his New England conscience that prompted him to be so regular in his meetings with his scientific colleagues. His motive was a higher one than that. It was his absorbing desire to advance his science by every means within his power. The list of scientific bodies of which he was a member was a long one, but every one of them gained much from his membership and from his presence at its meetings. He was regular in his attendance; always ready to contribute papers; always modest in his estimate of the importance of his own work; always generous in his appreciation of the work of others; always ready with a word of sympathy, or encouragement, or fellowship.

The productivity of Blue Hill Observatory has been remarkable, especially when it is remembered that this activity was the result of the support and inspiration of one man. The study of cloud heights, velocities, movements and methods of formation at Blue Hill was one of the most complete investigations of the kind ever undertaken. The first series of measurements in America of the height and velocity of clouds, by trigonometrical and other methods, was made at Blue Hill in 1890-91. These measurements were repeated in 1896-97, as a part of an international system.

It was at Blue Hill that the modern methods of sounding the air by means of self-recording instruments lifted by kites were first developed and effectively put into practice (1894), methods which have now been adopted by meteorological services and scientific expeditions in all parts of the world. The use of cellular kites flown with steel wire and controlled by a power windlass originated at Blue Hill. Grants for carrying on this kite work were obtained from the Hodgkins Fund.

It was Rotch who, in 1901, during a voyage across the Atlantic, first obtained meteorological observations by means of kites flown from the deck of a moving steamer, thus indicating the feasibility of a new way of securing information concerning the conditions of the free air over oceans and lakes. It was Rotch who, in 1904, secured the first meteorological observations by means of sounding balloons from heights of 5 to 10 miles over the American continent, and who, in 1909, made the first trigonometrical measurements of the flight of pilot balloons in the United States. In 1905-06 he joined his colleague, Teisserenc de Bort, in fitting out and taking part in an expedition to explore the tropical atmosphere over the Atlantic Ocean by means of kites and pilot balloons, an undertaking which resulted in the collection of important data regarding the temperatures and movements of the upper air. But Rotch was not content with merely sending up kites and balloons. His enthusiasm in the study of the free air, and his desire to visit the mountain observatories of the world, led him to become a mountain climber of no mean ability. He ascended to the summit of Mont Blanc at least five times, and in South America and elsewhere he himself made meteorological observations at considerable altitudes on mountains, and carefully observed the physiological effects of the diminished pressure. He also took part in several balloon ascents, and was a member of more than one solar eclipse expedition. His studies of eclipse meteorology are among the most complete which have been made. Among his many contributions to the advancement of meteorology must also be mentioned his in-

vention of an instrument for determining the true direction and velocity of the wind at sea.

Professor Rotch was naturally intensely interested in the recent rapid development of aeronautics. His earlier training at the Massachusetts Institute of Technology, and his untiring zeal in the exploration of the upper air, combined to give him this interest. He turned his attention largely in that direction of late years. It was characteristic of him that, not content with the mere collection of data, and with investigations of theoretical interest, he always strove to make these results of practical use. Thus, soon after the establishment of his observatory, the issue of local weather forecasts was begun, and one of the last things which he published (in association with Mr. A. H. Palmer) was a set of "Charts of the Atmosphere for Aeronauts" confined to meteorology, and show most embodying many of the results of observations made at Blue Hill in a practical form for the use of airmen.

Professor Rotch's list of published papers and books comprises 183 titles. These cover a wide range of subjects, by no means strictly confined to meteorology, and show most emphatically how varied were their author's interests; how extended was his reading; how alert and progressive he was in all he undertook. These 183 titles in themselves furnish a satisfactory outline of the development of meteorological science during the past 25 years. In addition to the "Charts of the Atmosphere" just referred to, he published two other books, "Sounding the Ocean of Air" (1900) and "The Conquest of the Air" (1909).

Professor Rotch gave his support freely to a large number of scientific societies and undertakings. He was one of the pioneer and most enthusiastic members of the New England Meteorological Society. He was, for more than ten years (1886-96), one of the associate editors and one of the mainstays of the *American Meteorological Journal*, which did a unique work for American meteorology. He was a member of the Astronomical and Astro-

physical Society of America; a fellow and of late years librarian of the American Academy of Arts and Sciences; a member and trustee of the Boston Society of Natural History; a member of the American Philosophical Society, of the Physical Society of London, of the International Solar Commission, of the International Commission for Scientific Aeronautics, of the International Meteorological Committee; fellow of the Royal Meteorological Society (London); member of the Société Météorologique de France, of the Deutsche Meteorologische Gesellschaft, of the Oesterreichische Gesellschaft für Meteorologie and of many other societies.

He was lecturer at the Lowell Institute, in Boston, in 1891, and again in 1898. He was a member of the International Jury of Awards at the Paris Exposition (1889), and was then made a Chevalier of the Legion of Honor. He received the Prussian Orders of the Crown (1902) and Red Eagle (1905) of the Third Class in recognition of his services in advancing the knowledge of the atmosphere. The latest evidence of the high regard in which his scientific work was held abroad was his selection, by the French ministry of public instruction, as exchange professor at the Sorbonne for the year 1912-13. The official letter announcing this selection arrived in this country within a very few days after Professor Rotch's death.

He was a pioneer in a new science; an investigator, whose name is known wherever meteorological work is done; a loyal teacher who served without salary; a generous benefactor, who left to the university an enduring monument of his enthusiasm and untiring devotion to the science which he himself did so much to advance. His life and labor have been an inspiration to his scientific colleagues everywhere, but especially to those who were most closely associated with him in the work of his observatory, and in the department of the university of whose staff he was a valued member.

ROBERT DE C. WARD

HARVARD UNIVERSITY

*THE TRANSCONTINENTAL EXCURSION OF
THE AMERICAN GEOGRAPHICAL
SOCIETY*

THE American Geographical Society of New York celebrates this year the occupation of its new building on Broadway at 156th Street and the sixtieth anniversary of its founding. No form of celebration seemed so fitting as an excursion across the United States, in which an invited party of European geographers should make the journey in company with a number of American geographers, who would show the visitors the most significant of our geographical features; the excursion to be closed by a meeting in New York, when the visitors should be invited to give some account of what they have seen.

The plan thus outlined is now approaching its realization. The leading geographical societies of over a dozen European countries have been requested to select from among their members a number of proficient geographers whom the American Geographical Society may welcome on the excursion. The list thus constituted, with the addition of a few names otherwise invited, now includes over forty geographers from sixteen different countries; most of the delegates being professors in universities or officers of national geographic societies. The character of the party will be sufficiently indicated by announcing the coming of Partsch and Drygalski, Merzbacher and Jaeger, of Germany; Gallois, Margerie and Vacher, of France; Chisholm, Beckett and Falconer, of Great Britain; Niermeyer and Oestreich, of Holland; Leconte, of Belgium; Beltrán, of Spain; Silva-Telles, of Portugal; Brückner and Oberhummer, of Austria; Cholnoky and Teleki, of Hungary; Cvijič, of Serbia; Doubiansky and Schokalsky, of Russia; Andersson, of Sweden; Olufsen, of Denmark; Brunhes, Chaix and Nussbaum, of Switzerland, and Calciati, Marinelli and Vinceguerra, of Italy. It is safe to say that no such gathering of geographical crowned heads has ever been brought from Europe to America.

The Americans already enlisted, either as round-trip or as temporary members, include,

among professors of geography, Barrows and Cowles, of Chicago; Brigham, of Colgate; Bowman, of Yale; Davis and Ward, of Harvard; Dodge and Johnson, of Columbia; Fenneman, of Cincinnati; Jefferson, of Ypsilanti, and Martin and Whitbeck, of Wisconsin, as well as a number of scientific men from various parts of the country representing subjects allied to geography. Professor W. M. Davis, of Harvard University, has been appointed director of the excursion. The party as now made up includes over fifty round-trip members and some twenty or more temporary members. The number of participants is still to be somewhat enlarged, and correspondence (addressed to the director, Transcontinental Excursion American Geographical Society, Broadway at 156th Street, New York) is therefore invited from proficient geographers (men only) who may desire to take part in the excursion for longer or shorter periods, and who can aid the American members already enlisted in explaining our geographical features to the European members. Place on the special train in which the excursion will be made can not be promised to all applicants, but it is hoped that all professional geographers who wish to take part in the excursion can be accommodated in one or another part of the route. The excursion train will leave New York about August 22, and return in the early part of October.

The route of the excursion includes Niagara, Detroit, Chicago, Madison, St. Paul—Minneapolis—probably Duluth and the Iron region—the Yellowstone Park, Spokane, Seattle, Tacoma, Portland—probably San Francisco, possibly the Yosemite Valley—Salt Lake City, Grand Junction, Denver, Albuquerque, the Grand Canyon of the Colorado in northern Arizona, Kansas City, St. Louis—possibly Memphis, Birmingham and Chattanooga—Washington and New York. Numerous stops will be made at points of geographical interest on the way. A most generous hospitality is promised at many places, where the party will be entertained in local clubs and taken about in automobiles. The cities of the far northwest are particularly

active; they are planning to take the excursionists up Mt. Rainier through the superb forest that clothes the lower slopes of this great volcano, to the hotel situated near the timberline, whence the glaciers of the higher slopes may be seen; and also to Crater Lake, the waters of which occupy a huge cavity of engulfment in a once lofty volcano, one of the most remarkable features of the west, although as yet not widely known. Two days will be spent in Washington, where visits will be made to various scientific bureaus of the government. The final meeting in New York will be made the occasion of a more general invitation than can be given for a limited excursion on a railway train; and at that time, it is desired that the European geographers should have opportunity of meeting a large number of their American colleagues. Due announcement will be made of the place and date of this final meeting, as well as of the speakers and the subjects that they will treat.

SCIENTIFIC NOTES AND NEWS

At the meeting of the London Institution of Electrical Engineers on May 16, a marble bust of the late Lord Kelvin was presented to the institution on behalf of Lady Kelvin.

SOME of the associates and students of Dr. Simon Flexner during the period from 1899 to 1904, when he was professor of pathology at the University of Pennsylvania, have presented to the university a portrait showing Dr. Flexner in his laboratory, painted by Adele Herter, of New York City.

At the annual meeting of the American Academy of Arts and Sciences, held on May 8, 1912, it was voted, upon the recommendation of the Rumford Committee, to award the Rumford premium to Frederic Eugene Ives for his optical inventions, particularly in color photography and photo-engraving.

THE Bessemer gold medal of the British Iron and Steel Institute has been awarded to Mr. John Henry Darby. Mr. Darby's connection with the iron and steel trades is best known from his association, as far back as in

the year 1880, with the introduction of the basic process. The first open-hearth furnaces for the manufacture of steel on a large scale erected in Great Britain were those built under Mr. Darby's superintendence at Brymbo.

THE congratulations of the council of the Chemical Society, London, have been offered to Mr. E. Riley, who has completed sixty years of fellowship, and to Major C. E. Beadnell, R.A., Mr. H. O. Huskisson and Mr. F. Norrington, who, during 1911, attained their jubilee as fellows.

MR. MARK A. CARLETON, for the past eighteen years in charge of grain investigations in the Bureau of Plant Industry, and well known as the introducer and propagator of Durum wheat and the Swedish select oat, has resigned his present position to take charge of the work of the Pennsylvania Chestnut Tree Blight Commission.

MR. C. E. CRAIG, instructor in agronomy in Purdue University, has accepted the position of agronomist in the Polytechnic School at Porto Alegre, Brazil.

DR. MAURICE J. BABB, assistant professor of mathematics at the University of Pennsylvania, has been elected president of the Association of Teachers of Mathematics of the Middle States and Maryland.

MR. H. C. K. PLUMMER has been elected, as we learn from *Nature*, by the board of Trinity College, Dublin, to be royal astronomer in Ireland, in succession to Dr. E. T. Whittaker, who was recently elected professor of mathematics at Edinburgh University. Mr. Plummer is the son of Mr. W. E. Plummer, director of the Liverpool Observatory, and has been second assistant to Professor H. H. Turner at the Oxford University Observatory since 1901.

At the annual meeting of the British Institution of Civil Engineers, held on April 30, the following were elected president and vice-presidents: *President*, Mr. Robert Elliott-Cooper; *vice-presidents*, Mr. A. G. Lyster, Mr. B. H. Blyth, Mr. J. Strain and Mr. G. Robert Jebb. The council of the institution has made the following awards for papers read

during the session 1911-12: Telford gold medals to Messrs. E. and W. Mansergh; a George Stephenson gold medal to Mr. R. T. Smith; a Watt gold medal to Mr. A. H. Roberts; Telford premiums to Messrs. J. Goodman, A. B. McDonald, G. M. Taylor, D. C. Leitch, W. C. Easton and D. H. Morton; and the Manby premium to Mr. S. H. Ellis.

At his own request and on account of physical disability, after a steady teaching service of over thirty-six years, by vote of the board of regents of the University of Minnesota, Arthur E. Haynes, professor of engineering mathematics, has been retired. The board has passed the following resolution: "Voted to express the appreciation of the board not only of the professional services of Professor Haynes, but of his personal devotion, his influence for the highest type of living and his loyalty to the university."

MR. WALTER E. ARCHER, C.B., who, as assistant secretary, has been in charge of the Fisheries Division of the Board of Agriculture and Fisheries since its establishment in October, 1903, has been compelled to retire from the public service owing to ill-health. His retirement took effect on May 1.

It is stated in *Nature* that the services of the official guide to the collections at the British Museum, Bloomsbury, have been so highly appreciated that a similar officer has been appointed, experimentally, at the Natural History Museum, South Kensington. Mr. J. H. Leonard has been selected for the position. The guide will make two tours of the museum daily, each tour lasting an hour. Provision will also be made for special tours, and for these, special application will have to be made.

THE consul general of Uruguay and six members of a commission of agricultural engineering are visiting our colleges of agriculture. The commission is on a world tour to study agriculture in different countries.

PROFESSOR HENRY B. WARD spoke on May 8 before the Medical Research Club of Cincinnati on "Recent Discoveries of Value in the Accurate Diagnosis of Human Parasites," illustrating the talk with material from the

zoological research laboratory of the University of Illinois. On May 10 he delivered the convocation address at the University of Cincinnati on the topic "The Prolongation of Life." While in Cincinnati he met with the committee of the university on the formulation of a constitution and at the request of President Charles W. Dabney discussed some of the general problems involved in this work.

PROFESSOR LAUDER W. JONES, University of Cincinnati, lectured before the students of chemistry, Central University of Kentucky, Danville, on Friday, May 10, his subject being "Some Historic Text-books and their Authors."

ON May 14 Professor W. Bateson gave the first of two lectures at the Royal Institution on "The Study of Genetics."

It is proposed to endow a pathological laboratory at St. Vincent's Hospital, New York, as a memorial of Dr. William Francis Norman O'Loughlin, the senior medical officer of the *Titanic*, in which he went down after rendering all possible assistance in saving others. Dr. O'Loughlin had been forty years in the service of the White Star Line.

PRINCE DAMRONG, minister of the interior in Siam, has founded a Pasteur Institute in memory of his daughter, who died of hydrophobia.

SIR FREDERICK WALLACE, an eminent London surgeon, has died at the age of fifty-three years.

THE death is also announced of M. Eugene Caventou, the distinguished organic chemist, president of the Paris Academy of Medicine in 1897.

THERE is existing a vacancy in the position of chief of drainage investigations in the Office of Experiment Stations, Department of Agriculture, Washington, D. C., at a salary of about \$4,000 per annum. The government is endeavoring to find the best man available for this work and has no particular individual in view. Applications for the examination will be accepted until June 10. Applicants should have a broad training in civil engineer-

ing; experience in making and passing upon drainage surveys and plans, with special reference to the requirements of the drainage of large tracts of agricultural lands; familiarity with drainage laws and administrative organization, cost of construction of drainage systems, etc. They should also be qualified to plan and conduct research along drainage lines, and to make reports and prepare publications on drainage subjects. Five years' experience as a drainage or hydraulic engineer, exclusive of any similar experience obtained in connection with university studies, is a prerequisite for consideration for this position.

THE U. S. Civil Service Commission also announces an examination to fill a vacancy in the position of assistant pharmacologist in the Bureau of Chemistry, at \$1,800 to \$2,000 per annum. This position affords opportunity for study and research in pharmacology and physiology in the broadest sense, the laboratory equipment being of the best. The person appointed to this position, if he proves capable of conducting the work, may expect reasonable promotion.

AN invested fortune yielding \$100,000 annually, a palatial mansion on the Boulevard Haussmann, and one of the finest private art collections in Europe have been bequeathed to the Institute of France by Mme. Edouard André.

THE Austrian government has purchased for about \$600,000 the only two radium mines at Joachimsthal which were owned by private individuals. It is estimated that the two mines will yield annually about 3 grams of radium. Plans are under way for the development of Joachimsthal as a resort for the treatment of disease by radium.

A PARTY will leave Cornell University on May 25 for the purpose of investigating the biology of the Okefenokee Swamp in southeastern Georgia. The fauna and flora of this extensive and in many respects unique swamp have heretofore almost entirely escaped the attention of naturalists. The eastern part of the swamp consists of vast inundated

"prairies," while on the western side there are extensive heavily wooded islands. Much of the swamp is a sphagnum bog, whence the Indian name, originally spelled "Ouaqua-phenogaw," meaning "trembling-earth." The personnel of the party will consist of Professors C. R. Crosby and J. Chester Bradley, Dr. A. H. Wright, Messrs. M. D. Funkhouser, M. D. Leonard, A. R. Cahn and S. C. Bishop, of Cornell University, and F. Lee Worsham, state entomologist of Georgia. Dr. Wright and Mr. Cahn will give their attention to the vertebrates, and Mr. Cahn also to collecting fleas and Mallophaga. An extensive series of blood smears will be made, for the detection of blood-parasites. The other members of the party will devote their attention to insects, especial attention being given to aquatic forms. The party expect to remain in the swamp from eight to ten weeks.

Two more American professors will start in a short time on a trip around the world under the Kahn Foundation for the Foreign Travel of American Teachers. They are William Erskine Kellicott, Ph.D., professor of biology in Goucher College, Baltimore, Md., and Ivan Mortimer Linforth, A.B., A.M., professor of Greek in the University of California, their appointment having been made this week. The fellowships to which they have been appointed carry with them a stipend of \$3,000 each, and an additional \$300 for the purchase of souvenirs, books, etc. The fellowships are unique in that the incumbents are required only to make the trip around the world. The choice of routes, countries visited and length of stay in any one place are left to the discretion of the fellows, their only duty being to see as many peoples and countries as possible. The object of the founder was to give teachers an opportunity to carry on their work from a broader and more international point of view. The first appointments on this foundation were made last year. Francis Daniels, A.B., A.M., Ph.D., professor of Romance languages at Wabash College, Crawfordsville, Ind., and John Hanson Thomas McPherson, A.B., Ph.D., professor of history and political science at the Univer-

sity of Georgia, are now abroad, and are due to reach this country during the summer months. The foundation was established by M. Albert Kahn, of Paris, France, and is administered by Edward D. Adams, Nicholas Murray Butler and Henry Fairfield Osborn, of New York City, Charles W. Eliot, of Cambridge, Mass., Charles D. Walcott, of Washington, D. C., and Frank D. Fackenthal, secretary of Columbia University, as secretary of the board.

THE Bureau of American Ethnology of the Smithsonian Institution has issued a dictionary of the Biloxi and Ofo languages, accompanied by texts of a number of stories embodying mythology and folklore of the two tribes. This volume is largely the result of painstaking investigation and study on the part of the late Rev. J. Owen Dorsey, to which Dr. John R. Swanton, of the bureau, has added the Ofo material, besides arranging and editing (from the linguistic point of view) the entire work.

MESSRS. WITHERBY & Co. are shortly publishing "A Hand-list of British Birds," giving a detailed account of the distribution of each bird in the British Isles, and a general account of its range abroad, together with details of the occurrences of rarities. The Hand-list is the joint work of Messrs. E. Hartert, F. C. R. Jourdain, N. F. Ticehurst and H. F. Witherby.

EXPERIMENTS have been carried out at Nawalia, Northern Rhodesia, respecting the transmission of human trypanosomes by *Glossina morsitans* Westw., and on the occurrence of human trypanosomes in game. The results, so far as they are at present ascertained, are presented by Mr. Allan Kinghorn and Dr. Warrington Yorke in the "Annals of Tropical Medicine and Parasitology," issued by the Liverpool School of Tropical Medicine, forming the first interim report of the Luangwa Sleeping Sickness Commission, British South Africa Company. The summary of the report as given in the London *Times* is as follows: (1) The human trypanosome, in the Luangwa Valley, is transmitted

by *Glossina morsitans* Westw. (2) Approximately 5 per cent. (4.76) of the flies may become permanently infected and capable of transmitting the virus. (3) The period which elapses between the infecting feed of the flies and the date on which they become infective is approximately 14 days. (4) An infected fly retains the power of transmitting the disease during its life, and is infective at each meal. (5) Mechanical transmission does not occur if a period of 24 hours has elapsed since the infecting meal. (6) Some evidence exists to show that in the interval between the infecting feed and the date on which transmission becomes possible the parasites found in the flies are non-infective. (7) *Glossina morsitans*, in nature, has been found to transmit the human trypanosome. (8) Certain species of buck, viz., waterbuck, hartebeest, mpala and wart-hog, have been found to be infected with the human trypanosome. (9) A native dog has been found to be infected with the human trypanosome.

UNIVERSITY AND EDUCATIONAL NEWS

MRS. JOHN STEWART KENNEDY has given to New York University a Hall of Philosophy, costing in the neighborhood of \$90,000. It is to be known as the Cornelius Baker Hall of Philosophy in memory of Mrs. Kennedy's father, who was one of the founders of the university.

OBERLIN COLLEGE has received an anonymous gift of \$10,000 for library endowment. It is expected that a considerable portion of this will be devoted to completing the files of scientific periodicals and journals, with especial emphasis on the contemporary literature on Eugenics.

THE King of Siam has sanctioned a scheme for the establishment of a University of Bangkok. There will be eight faculties, including medicine, law, engineering, agriculture, commerce, pedagogy and political science.

The Experiment Station Record states that an agricultural school is to be established in Melilla, Morocco, under Spanish auspices. This school will have for its objects the dis-

seminating of practical instruction regarding improved methods, and their demonstration upon the estate, which will be conducted as a model farm, and also on demonstration fields in adjoining sections. It is estimated that about \$48,000 for buildings and equipment, and \$21,000 annually for maintenance, will be required.

THE William Rainey Harper Memorial Library at the University of Chicago is to be dedicated on June 10 and 11, 1912. A special effort will be made to have the alumni attend the dedicatory exercises, which will be held in Harper Court, bounded on the south by the Library, on the west by Haskell Oriental Museum, and on the east by the Law Building. For the next few years the first floor of the new building will be used for class-rooms and will also contain the Harper Assembly room. Eventually, however, the entire floor is to be utilized as a stack-room.

THE trustees of Cornell University have voted to approve the recommendation of the faculty of the College of Agriculture and the university faculty to grant hereafter the degree of bachelor of science, instead of bachelor of science in agriculture, for the completion of the course in the College of Agriculture.

AT Princeton University, William F. Magie, Henry professor of physics, has been elected dean of the faculty to succeed Professor H. B. Fine. Professor Fine retains the deanship of the department of science. He will spend the coming academic year in Europe.

DR. M. E. WADSWORTH, for the past five years dean of the School of Mines of the University of Pittsburgh, has resigned, his resignation to take effect on June 30. Mr. S. A. Taylor, C.E., an alumnus of the university, has been appointed dean.

PROFESSOR H. P. BAKER, of the Pennsylvania State College, has accepted a position at Syracuse University as dean of the State College of Forestry, established in 1911 by the New York legislature with an initial appropriation of \$55,000.

PROFESSOR RICHARD S. CURTIS, of the University of Illinois, has resigned to become professor of organic chemistry at the Throop Polytechnic Institute, Pasadena, California, and L. L. Burgess, associate in chemistry, has resigned to become assistant professor of analytical chemistry at the University of Saskatchewan, Canada.

THOMAS C. BROWN, Ph.D. (Columbia, '09), assistant professor of geology in the Pennsylvania State College, has been appointed associate in geology at Bryn Mawr College.

MR. R. J. S. PIGOTT has been appointed assistant professor of steam engineering in Columbia University, a newly established position in the School of Engineering.

H. LEE WARD, of Swarthmore College, has been appointed instructor in chemistry in Wesleyan University.

THE following new appointments to instructorships have been made in the department of chemistry of Columbia University: Andrew Bender, Columbia University; R. H. Lombard, Columbia University; Arthur Edgar, Massachusetts Institute of Technology; Dr. Frederick Barry, Harvard University; R. F. McCrackan, Columbia University; Harry L. Fisher, Cornell Medical School; Robert M. Isham, Columbia University.

PROFESSOR FRIEDRICH CZAPEK, of the University of Prague, has been appointed to the chair of plant physiology and pathology in the Imperial College of Science and Technology, London.

DISCUSSION AND CORRESPONDENCE

A PROTEST AGAINST CHANGING THE INTERNATIONAL CODE OF ZOOLOGICAL NOMENCLATURE

IT is well known to all who have had to deal with questions of nomenclature that much of the confusion in the application of generic names in the past has been due to the lack of system in determining the type of a genus.

It is a matter of small importance just how the type is determined so long as every one uses the same method and the method is sufficiently clear and definite to yield uniform results in the hands of different investigators.

The method of elimination which was for some time in use was unsatisfactory in this respect. It proved impossible to formulate rules by which the type of a composite genus could be "eliminated" by several investigators with the same result.¹

Systematists naturally demanded a simpler method which would give uniform results in the hands of different persons, and the "first species" method met with very general support when the question of a change was raised. The matter came before the International Commission on Zoological Nomenclature at Boston in 1907 and resulted in the adoption, as a compromise, of the method now incorporated in the Code, whereby the action of the first author who designates a type for a polytypic genus is held as binding in all cases where the type is not settled by original designation, tautonymy, etc., as enumerated in Art. 30, rules "a" to "d."

This method is definite and has been accepted by all zoologists who follow the International Code. The types of thousands of genera have been recently determined by this method and many complicated questions of nomenclature have been settled in accordance with its rules. The Commission, with the cooperation of subcommittees, has even begun to prepare lists of authoritative names for genera in various departments of zoology, based upon the rules now in use.

Zoologists began to feel that stability and uniformity were at last in sight—but no! We are recently in receipt of a circular signed by a number of European zoologists advocating a return to the method of elimination and urging that the proposition be brought, not before the Commission on Nomenclature, but before the entire Zoological Congress!

It is hard to see how any zoologist can seriously support such a proposition, especially at the present time, when such satisfactory progress toward stability was being made. It is of course permissible to change the Code of Nomenclature where the rules are obscure or indefinite; but if we are to shift

back and forth to accommodate the views of now one coterie of investigators, now another, we might as well abolish all codes and lapse into nomenclatural chaos.

The return to the elimination method would not only reestablish the chaos in generic names from which we are just emerging, but would undo all the careful work in type determination which has been accomplished in the past five years as well as shake our faith in the permanency of any action of the Commission.

The proposition, moreover, to bring such questions before the entire Congress instead of the Commission on Nomenclature is preposterous. The determination of questions of nomenclature can only be effected by men who have had long experience in this line of work and many members of the Congress who are not systematists have little or nothing to do with nomenclature. For this very reason the Commission was appointed by the Congress and now to propose to ignore it is little short of insult.

One can not but suspect that some of the signers of this petition have been influenced by the entirely erroneous plea that the changes in well-known generic names are all due to the present method of type determination and that the return to elimination would restore the familiar names. Nothing is farther from the truth. Every method of type determination will involve changes in generic names and probably in about equal numbers, but the greatest number of changes is due not to the method type designation nor yet to priority, but to excessive generic subdivision. There would probably be a great protest were it proposed to overthrow the genus *Picus*, the classic name for woodpeckers, but, as a matter of fact, such action would affect the name of but one species of bird, as all other woodpeckers have been removed from this genus!

It is to be hoped that zoologists attending the Zoological Congress at Monaco in 1913 will realize the seriousness of this matter and not permit a technical question of this kind to be taken outside of the Commission on Nomenclature expressly established for its

¹ Cf. SCIENCE, Vol. XXIV., p. 560.

consideration; and further that the members of the Commission will not countenance a change in the Code which is both uncalled for and unnecessary, and which will render void much valuable work and threaten the success of the whole movement toward uniformity in zoological nomenclature.*

"GENES" OR "GENS"?

AFTER discussing the significance of the word "phenotype" in SCIENCE for April 26, Dr. O. F. Cook states that

Pluralizing the word "gen" is another difficulty encountered by geneticists. Johannsen used the term mostly in its German plural form, *Gene*. Our writers have added another letter making a double plural, "genes," something like "memorandas."

This statement does not correctly represent the origin of the English word "gene" and its plural "genes," now generally used by writers of English papers on genetics. In Darwin's word "pangen" English usage renders the last syllable short, though the two halves of the word contribute equally to its meaning. When the word is transferred to the German, as has been freely done, a law of the German language makes both syllables long. On this account the German word "*Pangen*" better expresses the meaning involved than does the English word "pangen." Johannsen's word "*Gen*," like the last syllable of the German word "*Pangen*," from which it was directly de-

rived, is long in quantity. On transferring this happily chosen word to English it was desired to maintain the long quantity of the German word, and the addition of a final *e*, following a general law of English philology, was made simply for this purpose. The English word "gene" (pronounced *gēn*) is thus seen to bear no direct genetic relation to the German plural "*Gene*," and their likeness in spelling is purely a coincidence. The word "genes" is consequently not a double plural and not at all like "memorandas."

There is a further reason why the word "gene" should be preferred. This word must be used commonly in the plural form, but there is already a word "gens" in rather common literary use and having, at least sometimes, a genetic meaning.

Regarding the definition of "phenotype," few who carefully read the passage translated by Dr. Cook from Johannsen's book will agree with the translator that "phenotype" as used by its author was ever anything but an abstraction. "Centers among series of variations around which the variants are grouped" must always be abstractions, and yet they are, as Johannsen rightly says, "measurable realities." Every individual organism possesses an external appearance and a fundamental constitution, and is therefore a representative of some phenotype and of some genotype. The words "phenotype" and "genotype" were never intended to be limited to *statistically investigated* organisms. Statistical investigation may *discover*, *measure* and *describe* phenotypes, but it does not *create* them. Phenotypes and genotypes exist among Mendelian hybrids just as among all other organisms, and my use of the Mendelian categories to illustrate the proper use of these two words involves no "new version of phenotype."

CRYSTALLOGRAPHIC TABLES

TO THE EDITOR OF SCIENCE: The letter of Professor Oliver Bowles, of the University

* Since the above was written I have read Professor Nutting's article in SCIENCE criticizing the powers of the commission and the difficulty of bringing a question of nomenclature before the congress for discussion. He fails to realize that these very facts give the code its strength and establish confidence in the permanency of nomenclature based upon it. We do not desire rules that appeal to this man or that, but rules that shall be *permanent* and the International Congress was perfectly right in making it as difficult as possible to change the code.—W. S.

of Minnesota, which appeared in a recent issue of *SCIENCE*,¹ opens up again the much discussed question of the presentation of the subject of crystallography to undergraduate classes.

Professor Bowles apparently takes the view that the fundamental laws of this science should be studied through their application to concrete examples. It has been the experience of the writer that, in general, the efforts of teachers of crystallography have not been directed with sufficient force to the lucid presentation of these fundamental laws. In spite of the many varieties of models in glass, wood, paper and plaster of Paris, now at the disposal of the modern teacher of this science, his classes often have only a vague notion of:

1. The mechanical relations of the directions of particle-attraction.
2. The all importance of symmetry as a basis of crystallographic study.
3. The application of the above to crystallographic zones.

With regard to Professor Bowles's suggestion respecting tables for determination of axial ratios, the writer desires to point out that the use of such tables must of necessity presuppose the knowledge on the part of the student of which face of the crystal measured represents a unit plane. Taking the axial ratios of a number of common tetragonal minerals such as:

	\bar{c}	$2\bar{c}$	$3\bar{c}$
Apophyllite	1.2515		
Wernerite4384		1.3052
Zircon6404	1.2808	
Rutile6441	1.2882	
Cassiterite6723	1.3446	
Xenotime6187	1.2374	

it will be readily seen that for each of these species a pyramid could be selected which would give a resulting axial ratio fairly close to some pyramid of each of the others. In point of fact, in the above series the difference in angle, measured from the prism, between the pyramid corresponding to 1.2374 (lowest value) and 1.3446 (highest value) is only $5\frac{1}{2}^\circ$

¹ *SCIENCE*, April 12, 1912, pp. 576-577.

—a difference not easy of determination with a contact goniometer in the hands of an inexperienced student. Such instances could be multiplied many times.

In answer to Professor Bowles's first question as to whether tables of axial ratios would be useful as an aid to crystal determination with the reflection goniometer, it has been the writer's experience (and undoubtedly that of every crystallographic investigator) that in 99 cases the name of the species under investigation is known before it is set up for measurement. In the rare and much to be desired hundredth case (that of a new species) the name would obviously not appear in any table.

To the chemical crystallographer, tables of the axial ratios of artificial crystals might be of use could a work of sufficient size to include them all be prepared, but even such a collection of tables would have to be very frequently revised.

H. P. WHITLOCK

DEPARTMENT OF MINERALOGY,
NEW YORK STATE MUSEUM,
ALBANY, N. Y.

TO THE EDITOR OF *SCIENCE*: If we may judge from the character of most of the text-books on crystallography, Mr. Bowles's suggestion in *SCIENCE* for April 12, that any phase of this subject should be turned into an "illuminating and interesting exercise" is certainly a novel one. Yet surely the demonstration of the "value of the science as a means of mineral determination" is the ideal way to bring it before the student, so that crystals shall be to him more than, as Goldschmidt has put it,¹ "a feared and hated collection of geometrical figures, of wood, plaster or pasteboard, with vertices and edges and bad Greek names, to be immediately forgotten on leaving school, and preferably never heard of again."

The writer has used tables similar to those described by Mr. Bowles for several years; thus far they have been mimeographed and handed around the class, but if elaborated and

¹ *Ann. d. Naturphilos.*, IX., 121.

collected into book form they would certainly be still more serviceable. The inclusion of all known minerals would be a very desirable feature, but the more important ones should be marked by bold-face type.

The necessity for repetition of each species would be in a large measure obviated if a complete discussion of the rules governing the orientation of crystals in general were presented. Even in the tetragonal system two values of c must be given unless the student is first taught to distinguish first from second order pyramids, by relative size of faces, presence of cleavage, direction of striations, etc. And in the more complex systems similar rules can be formulated. In fact, if such rules had only been collected and presented in an authoritative way in some text-book long ago the rather unfortunate confusion in the present usage in orienting even some common crystals—as, for instance, making the long prism-like faces of gypsum the pyramid—might have been avoided.

Yes, by all means, the preparation of such a list of tables should be undertaken. And perhaps it would be worth while to include similar tabulations of some of the physical properties of minerals, such as color, hardness, etc., on a more elaborate scale than those in Dana's text-book, for instance.

EDGAR T. WHERRY

DEPARTMENT OF GEOLOGY,
LEHIGH UNIVERSITY

CHANGES OF BODILY FORM IN DESCENDANTS OF IMMIGRANTS

TO THE EDITOR OF SCIENCE: Four years ago Professor F. Boas, of Columbia University, was intrusted by the U. S. Immigration Commission with an investigation of the bodily characteristics of descendants of immigrants in America. The results of this undertaking were published two years ago in his report entitled "Changes in Bodily Form of Descendants of Immigrants" (Washington, 1910). In this report Dr. Boas questions the generally accepted theory of anthropologists that the form of the head is one of the most unchanging characteristics of human races,

and concludes that it is subject to "far-reaching" changes in type due to the transfer of the races of Europe to American soil.

Last year I wrote a critique of this report entitled "Professor Boas's New Theory of the Form of the Head—A Critical Contribution to School Anthropology,"¹ in which I took the ground that Professor Boas's own figures do not warrant his conclusion that the shape of the head is influenced by a new environment.

In a recent number of SCIENCE² there appeared a reply to my critique. As the general reader can not get a clear conception from this reply either of the nature of Boas's report of 1910 or of the salient points of my criticism of it, I venture to call attention to the following statements:

Professor Boas in his report of 1910 ignores all previous theories of this most complicated problem (see especially pp. 7, 31, 32, 51) and writes as follows:

Children born more than a few years after the arrival of the immigrant parent in America develop in such a way that they differ in type essentially from their foreign-born parents. These differences seem to develop during the earliest childhood and persist throughout life. It seems that every part of the body is influenced in this way; and even the form of the head, which has always been considered as one of the most permanent hereditary features, undergoes considerable changes. . . . The importance of this entirely unexpected result lies in the fact that even those characteristics which modern science has led us to consider as most stable are subject to thorough changes under new environment. (This is quoted in the "Introduction" to the Report.)

The head form, which has always been considered as one of the most stable and permanent characteristics of human races, undergoes far-reaching changes due to the transfer of the races of Europe to American soil (p. 7).

This fact is one of the most suggestive ones discovered in our investigation, because it shows that not even those characteristics of a race which have proved to be most permanent in their old home remain the same under our new surround-

¹Published in the *American Anthropologist*, XIII., 1911, 394-436.

²April 5, 1912, 537-40.

ings; and we are compelled to conclude that when these features of the body change, the whole bodily and mental make-up of the immigrants may change (p. 8).

The influence of American environment upon the descendants of immigrants increases with the time that the immigrants have lived in this country before the birth of their children (p. 9).

The influence of American environment makes itself felt with increasing intensity, according to the time elapsed between the arrival of the mother and the birth of the child (p. 17).

The type of the immigrants changes from year to year, owing to a selection which is dependent upon the economic conditions of our country. This is shown by the fact that after the panic of 1893 a sudden decrease in the general development of immigrants may be observed, which persisted for several years. A similar change seems to have taken place after the panic of 1907. (Here Boas gives his Table VIII. and Fig. 17, which includes stature, length of head, width of head, cephalic index, and width of face—showing the “general deterioration” in the type of immigrants after the panic of 1893; pp. 28–29.)

That there are not only decided changes in the rate of development of immigrants, but there is also a far-reaching change in the type—a change which can not be ascribed to selection or mixture, but which can only be explained as due directly to the influence of environment. This conclusion has been tested, and in many different ways, and seems to be amply proved. It has been stated before that, according to all our experiences, the bodily traits which have been observed undergo a change under American environment belong to those characteristics of the human body which are considered the most stable (p. 32).

A feature that is particularly noticeable is the general drop of all the absolute measurements after the year 1894. An attempt to combine all the material, adult and children, for these years, brings out the sudden drop after 1893 even more clearly, and a similar phenomenon is repeated between the years 1907 and 1909. For this reason I am inclined to believe that the type of immigrants is directly affected by financial panics (p. 39).

It would seem that the effect of American environment takes place almost immediately after the arrival of the parents (p. 43).

I think, therefore, that we are justified in the conclusion that the removal of the east European

Hebrew to America is accompanied by a marked change in type, which does not affect the young child born abroad and growing up in American environment, but which makes itself felt among the children born in America, even a short time after the arrival of the parents in this country. The change of type seems to be very rapid, but the changes continue to increase; so that the descendants of immigrants born a long time after the arrival of the parents in this country differ more from their parents than do those born a short time after arrival of the parents in the United States (p. 52).

In addition to that I may cite also Boas's explanation of his Fig. 17.

The most striking feature of the diagram is the general decrease in all measurements (viz., stature, length of head, width of head, cephalic index, width of face) in the period following the year 1894, which indicates that the arrivals during the period following the panic of 1893 were underdeveloped in every direction. The increase in the cephalic index during the same period does not contradict the data contained in the other curves (i. e., curves for stature, length and width of head, and width of face), because the index is not an absolute measurement, but the ratio between length of head and width of head. A preliminary tabulation of the measurements after 1907 shows a similar decrease to the one noted here. This decrease is perhaps due to the panic of 1907 (p. 29).

I ventured to characterize this theory as “*environmental-economic*”; and then pointed out that it is untenable, because of many biological and methodological inaccuracies. Not desiring to repeat my former discussion here, I refer the reader to my critique in the *American Anthropologist*.¹

In this connection I may call attention to a criticism of the same report by the well-known Italian anthropologist, Professor G. Sergi, of the University of Rome, entitled, “The Pretended Change in the Physical Forms of the Descendants of Immigrants in America” (reprint from the *Rivista Italiana di Sociologia*, Jan.–Feb., 1912). He says:

The numerical series, the diagrams, the claims, the seriousness of the New York anthropologist (Boas) lend credit to the conclusions above men-

¹ Op. cit., 1911, pp. 394–436.

tioned (viz., Boas's conclusions), to the great surprise of many anthropologists, some of whom have expressed their incredulity. Not having seen any criticism of Boas, but sounds of retraction on the part of Boas himself, I wish to show how the method which he followed is inexact, and why we can place no faith in his surprising conclusions (p. 4).

Professor Sergi confines himself to the cephalic index, but he rightly says that what is true of the form of the head is equally true of the other data. He continues:

If we consider the other physical forms of the descendants of immigrants, our conclusion acquires a wider and more general significance, viz., that no change of human physical characteristics through the influence of environment has been proved. If, as a matter of fact, there is no change in the physical forms of immigrants in America, the process according to which this change must have theoretically come about is an absurd one (p. 10).

The main points of my criticism of Professor Boas's report of 1910 refer not to classification of the cephalic index, but to the *causes* of its changes. The conventional classification of head forms may or may not be irrelevant. My critique did not treat this problem at all; it only recalled to Professor Boas the fact that he uses familiar technical terms such as "type," "longheaded," "short-headed," which everybody knows but which do not agree with his figures or tables. He says:

The east European Hebrew who has a very round head, becomes more long-headed; the south Italian, who in Italy has an exceedingly long head, becomes more short-headed (p. 7); that the long-headed foreign-born Italians become more short-headed in America (p. 51).

In regard to the cephalic index Professor Sergi, after presenting a table on page 7 of his critique, says:

If we examine the averages (media) of the cephalic index, we doubtless find that for those born in America there is a diminution of from one to two units (or a little more) as compared with those born outside of America. It is this which Boas has shown in his numerous tables. But does this diminution in the averages show, as

Boas pretends, a change in the form of the skull of Jews born in America? Apparently, yes, but in reality, no; because the averages are simply the rude expressions of the composition of the series (p. 7).

That Professor Boas's many sweeping conclusions on the form of the head are based on averages only is shown throughout his report (see especially, pp. 8, 43, 9, 12). Dr. Sergi is right in saying:

The series vary in their composition as might be expected and the averages do not give the character of the composition. In fact these would seem to indicate that certain groups are more and others less brachycephalic while the truth is, that some groups contain more brachycephalics (p. 6).

On p. 8 Professor Sergi gives a comparison and concludes that the real result of it is that only the proportions of the classes are altered; and therefore while they exist in different proportions, there still exist dolichocephalics, mesocephalics, brachycephalics and hyperbrachycephalics among those born in America. Therefore this difference of proportion of the classes can not be said to depend on the change of the form of the skull, but upon the paternal and maternal ancestry, the Jews being immigrants from every part of Europe. Boas does not say from which group his subjects come. In other words, they are the children of every European nationality to which the Jews belong (p. 8).

On p. 10 Dr. Sergi says:

But Boas would have us also believe that the children of immigrants who live in America ten years or longer undergo a more distinct and pronounced change, while the parents undergo none whatever. We should then have to suppose that a general change must have been going on in the organism of the immigrants which modified their generative cells, the ova and the spermatozoa, so that in the embryonal and later development the organism of the children appears modified in form. Who can support such a theory? It appears even more absurd inasmuch as it operates in two directions opposed to each other, the brachycephalics seemingly tending toward dolichocephaly (*i. e.*, with the Jews), and the dolichocephalics tending toward brachycephaly (the case of the Sicilians), by virtue—says Boas—of the environment. The change in the generative cells of immigrants would have to follow in two opposite directions, being most rapid (according to Boas) in the immigrants

of any year and a little less rapid in those of ten. . . . Admitting the theory of the inheritance of acquired characteristics as proven, a change would have to appear in the parents after a long stay in the United States, and this change would have to be transmitted to the descendants; i. e., the cephalic, facial and other forms would first change in the parents and would then be transmitted to the children. But this is not the case; according to Boas such a change appears *ex novo* in the children as soon as the parents land in America or have lived here a year or two. This is absurd in theory and as a matter of fact these are not the conditions, as I have shown.

Finally, Dr. Sergi says that one is tempted to ask:

Why should the two types tend toward a common form in America? Is it because one finds there one fixed type, either absolutely dolichocephalic or decidedly brachycephalic? Not even such a justification exists, because America, both with regard to her natives and her immigrants, has always had dolichocephalics, mesocephalics and brachycephalics; hence there is no influence of environment which can tend to fix a single cephalic form in either natives or immigrants (p. 11).

The general reader ought to know these facts. The main purpose of my critique, as well as that of the present discussion, is not to answer but to raise the questions in regard to the causes of changes of the cephalic type. Whatever the *prima facie* explanation may be, the causes of the shape of the head can not be solved by Boas's new theory, because it is, as I showed in my critique, "based rather on a cross-section of the facts than on a genetic interpretation of them. It is only a genetic description and explanation of them that can give a trustworthy basis for a theory." Is it not a fact that in a considerable part of present-day anthropological, psychological and pedagogical writings one is led to think that the most primary phenomena have been examined with mathematical accuracy, when as a matter-of-fact there must have been left out of account numerous accompanying conditions which determined, to a greater or less extent, the results of the problem studied.

The main objection to Professor Boas's new theory of the changes in bodily form of

descendants of immigrants in America is that it finds only one causal relation, viz., that between figures and environment, ignoring all biological and methodological factors. He does that in spite of the most recent attempts of biologists to explain all organic and inorganic changes by the principles of "plural effects" and "the limits of possible oscillations" (see especially Petrunkevitch's "Gedanken über Vererbung," Freiburg, 1904). These modern biologists support their theories also by the logic of mathematics; so, for example, the formula comprising the ellipse, the parabola and the hyperbola (where r and Δ are polar coordinates):

$$r = \frac{ep}{1 - e \cos \Delta}$$

is capable of many solutions and thus creates many possibilities. I believe that Professor Sergi is perfectly warranted in characterizing as "absurd" an anthropological theory which claims that human bodily forms are plastic and can be moulded even during the "first generation" and "a short time after the arrival of parents under new surroundings."

To sum up. As the general reader knows, the form of the head is considered by anthropologists as the most unchanging physical characteristic of the human body, so that the scientists classify the race into a few cephalic types. Professor Boas, on the contrary, makes unwarranted, sweeping conclusions that even the shape of the head undergoes far-reaching changes in type due to the new environment, a new theory which is not justified by his own figures and is not based on scientific methods and on the required technique of experimental physical anthropology.

SCIENTIFIC BOOKS

Pflanzenphysiologie. By W. PALLADIN. Berlin, Julius Springer. 1911. Pp. vi + 310, figs. in text 180. Price M. 9, paper M. 8. The new plant physiology from the hand of

Dr. W. Palladin possesses a number of somewhat novel features that will be sure to render it interesting to those dealing with the fundamental principles of physiological science. The present German edition is a translation of the sixth Russian edition of the work, with alterations and additions.

The general view-point of the author and the mode of treatment which characterizes his work are well indicated in the first sentence of the introduction, wherein it is pointed out that the aim of plant physiology is to gain a complete and thorough knowledge of all the phenomena occurring in plants and ultimately to interpret these in terms of the principles of physics and chemistry. From this it may be expected, and it is indeed true, that the present work contemplates plant phenomena more from the standpoint of chemistry and physics than does any one of the already existing treatises on plant physiology.

The book before us is divided into two parts, the first (206 pages) on Nutrition and the second (95 pages) on Growth and Development. The eight chapter headings of Part I. are as follows: (1) Assimilation of Carbon and of the Energy of Sunshine by Green Plants, (2) Assimilation of Carbon and of Energy by Plants without Chlorophyll, (3) Assimilation of Nitrogen, (4) Absorption of Ash Constituents, (5) Absorption of Materials, (6) Movement of Materials in Plants, (7) Material Transformations in Plants and (8) Fermentation and Respiration. In the fourth chapter heading, logic would require the word *assimilation* instead of *Aufnahme* (absorption) for the latter word occurs, as *Stoffaufnahme*, in the fifth heading and the ash constituents are surely materials. The chapters of Part II. are entitled as follows: (1) General Conceptions of Growth, (2) Growth Phenomena Dependent on Internal Conditions, (3) The Influence of the Environment on Growth and Development, (4) Tendril Climbers and Twiners, (5) Movements of Variation [not due to growth], and (6) Development and Reproduction.

In Part I. the treatment is primarily chemical, and it is in respect to the chemical phe-

nomena of physiology that Palladin's book will prove most useful. In the fifth and sixth chapters, dealing with physical matters, the discussion is not as thorough as in the others. Chapter VI., for example, on the movement of material in the plant, contains no mention of H. H. Dixon's excellent and thoroughgoing study on the ascent of the transpiration stream, although the commonly cited experiments of Böhm and of Askenasy (demonstrating the great cohesion of water and the adhesion between it and mercury) are adequately presented. The discussion of root pressure, exudation and guttation is far less complete than that of many chemical processes of which we have no more adequate knowledge than we have of these, and the theoretical consideration of these fundamental occurrences is dismissed with the mere remark that "the causes upon which these phenomena depend have as yet not been determined" (p. 136). The matter of acid secretion (gland action in general) does not receive attention.

It is interesting to note that the toxic substance theory of soil fertility is given due consideration (p. 98 *et seq.*), and that, in this connection, a figure from a U. S. Bureau of Soils Bulletin and one from Dachnowski's recent studies on the toxicity of bog water are reproduced.

The growth of our general conceptions of respiration and related processes in organisms has recently been evidenced by a gradual bringing of the subject of fermentation into more and more intimate relation with so-called normal respiration. Palladin, once for all, places the whole matter upon a proper logical basis by opening the discussion with fermentation and following with the other topic. This, the reviewer thinks, is a marked advance in logical presentation, and it may do much toward clearing away the haziness which so generally obscures the whole subject of plant respiration.

The first two chapters of Part II. present, in an unusually concise manner, the main principles which underlie growth phenomena in general. The third chapter comprises general

but exceptionally complete discussions of the main relations between growth and the environmental factors. Nevertheless, the treatment of the influence of temperature lacks any mention of the conception of the temperature coefficient of growth activity, the chemical principle of Van't Hoff and Arrhenius as recently applied to physiological phenomena, although the author emphasizes the point that the phenological method of summer temperatures for the growing period can not be expected to give anything but the crudest of indications regarding the temperature relation of plants. It seems that enough has already been accomplished with the Van't Hoff-Arrhenius principle to warrant some treatment in a work of this kind. In the section on the influence of light, Palladin points out, as he has done before in the literature, that many of the developmental phenomena which are usually ascribed to light conditions should rather be referred to those of moisture. "All the characteristics of the development of etiolated plants may be explained by the altered transpiration conditions of these plants and by the resulting correlative influences of the individual organs" (p. 257).

In the last chapter of the book the author very happily presents the modern theory of internal secretions (developed from work with animals) as the basis of the physiological control of growth. "Hormones must doubtless also exist in plants." "The various phenomena of growth and of plant form will surely prove to be dependent upon different hormones" (p. 300). Such predictions, together with the activity of animal physiologists in this direction, can hardly fail to exert an accelerating influence upon the development of plant physiology.

In a general way, as clear and readable a book on this subject has not previously appeared. The style is always simple and nearly always characterized by strict logical sequence. The volume is almost without teleological implications, though the purist on this subject may smile at such an obsolescent section heading as, "The Necessity for the Movement of Materials" (p. 122), and the ex-

position thereof, which indicates that *necessity* here means *need* and not *cause*. Such must be regarded as mere slips into hitherto common and now more or less stereotyped modes of expression frequent in biological literature. The more fundamental principles are developed by the historical method, at once placing before the reader the present status of any given question and the names and methods of the workers to whom that status is due. Citations of literature are numerous, but not too numerous, and the western reader will be gratified in finding here a source for references and digests of some of the more important contributions not commonly cited in German, French and English works of this character.

On the whole, the reviewer is inclined to place Palladin's work at the head of the rather short list of books suitable to be placed in the hands of elementary students of plant physiology.

BURTON E. LIVINGSTON
THE JOHNS HOPKINS UNIVERSITY

Fourth Report of the Wellcome Tropical Research Laboratories at the Gordon Memorial College, Khartoum. Vol. A, Medical, 404 pp., 23 pls., 118 figs. in text. Vol. B, General Science, 333 pp., 20 pls., 101 figs. in text. ANDREW BALFOUR, M.D., Director. Published for the Department of Education, Sudan Government, Khartoum, by Bailliere, Tindall and Cox, London; Toga Publishing Co., New York City, agents for the United States.

These two highly specialized and elaborately illustrated volumes are filled from cover to cover with the results of research of high order. They are an epitome of the peaceful and effective conquest of the Sudan by the forces of modern science, of biology and chemistry, applied to the problems of the desert and the jungle in the tropics among a people submerged in ignorance and superstition and sunk in racial lethargy. The army of occupation is small, the staff of these laboratories numbering but eleven, including two officers, Captains Archibald and Fry, detailed

from the Egyptian army, and the Arab junior clerk. But the losses are heavy, for peace in the tropics claims its victims no less than war, in fatalities and sick leaves. The heavy loss to the laboratory caused by fire was promptly made good by the patron of the institution and its work has increased greatly in variety and magnitude in recent years.

This is noticeable in the accessions of volunteer helpers, Dr. Stevenson and others, and in applications for opportunity to work in the laboratory far exceed its facilities. The extensive work of this institution is carried up and down the Nile and its tributaries by the ubiquitous laboratory steamer *Culex* and by a floating laboratory equipped for researches remote from Khartoum.

For the first time the term "tropical" is added to the official title of the institution. This is particularly fitting, not only from the location, 15° 30' N., but also because this is the last outpost of civilization at the river gate to tropical Africa. It is also a natural center for the attack upon the problems which inhere in a desert environment and arise when man tames it by irrigation.

The medical volume is in large part devoted to tropical diseases of man, but likewise contains a number of important studies in bacteriology, protozoology, sanitary problems, and in that field of constantly increasing importance, comparative pathology. Lieutenant Colonel Mathias, president of the Sleeping Sickness Commission, reports upon the measures taken to check that great plague by segregation of sick natives in fly-free camps, clearing vegetation at all fords along the automobile road, and the introduction of treatment of the disease by atoxyl, metallic antimony and Ehrlich's "606."

Animal trypanosomiasis of the Sudan are discussed by Captain Fry in a very able manner. He notes that the natural conditions of this country tend to group both animal and human life in isolated colonies and hence to develop apparently isolated types of diseases which alter the virulence and characteristics of the trypanosomes which cause them. He accepts as the most reliable method of dif-

ferentiation the use of frequency polygons based on careful measurements of comparable preparations of the organisms, preferably from similar culture animals. This morphological basis in his opinion is more trustworthy than animal inoculations and reactions, culture, carrier, or the reaction to drugs, as a means of specific distinction.

An endoglobular developmental stage in the red-blood corpuscles similar to that found by Dr. Chagas in Brazil for *Schizotrypanum cruzi* is reported by Mr. Buchanon for *Trypanosoma brucei*. Captain Archibald has discovered human botryomycosis in the Sudan, the occurrence of acid-fast bacilli like *B. tuberculosis* in the lungs of the camel, and a new form of cutaneous leishmaniasis.

The work of the director, in addition to the heavy routine of administration, has included a study of the peculiar "infection granules" of fowl spirochaetosis including the life history of the spirochete in the ticks which serve as vectors. These results have important bearings on African tick fever and other spirochætal infections of man. The specific relations of the spirochete of human tick fever at Khartoum to *Spirochæte berbera* of Algiers is definitely established by Dr. Balfour. From his pen also comes a most useful paper on the fallacies and puzzles met with in a blood examination in the tropics and elsewhere, with a colored plate displaying the pitfalls which await the novice who searches for blood parasites, into which forsooth some experienced workers have been entrapped. A coccal form of the diphtheria bacillus is recorded from Khartoum, and Leishman nodules or non-ulcerating "oriental sores" are for the first time described.

An illuminating picture of sanitary administration is afforded in the director's account of "Some Aspects of Tropical Sanitation" in which is revealed not the militant hygiene of Panama, but another type of sanitary tyranny adapted to the life of an ignorant and fanatical people. To wage a successful war against conditions which tend to slay the white man and the black what is required is "education, such legislation as will crush the cul-

tured but ignorant fanatic and aid the worker, a devotion to the cause, and a well-trained band of helpers." In the Sudan where for many years smallpox was a dread calamity, it is now well-nigh as extinct as the dodo. The native is convinced of the beneficent results of Jenner's discovery and the anti-vaccinationist has not yet raised his voice in the desert.

The water supply of towns in the tropics and the bacterial standards to be enforced are discussed at length, with the general conclusion that the conditions are utterly different from those of civilized lands of temperate climates so that the problem of standards must be worked out anew in the tropics. Despite Clemesha's conclusions from analysis in India where soil contamination is great and sewage in streams relatively small, that the use of *Bacillus coli communis* in wider elastic sense as an indicator of contamination of water supplies in the tropics is inadequate and misleading, Dr. Balfour still concludes that this criterion gave useful results in detecting contamination in the municipal supply at Khar-toum.

The second volume, devoted to general science, contains a wider range of articles, from a treatise on municipal engineering in the tropics by members of the staff of Gordon Memorial College, to a treatise on the venom of the spitting snakes of Rhodesia and the Sudan. Here are the reports of the staff chemist, Dr. Wm. Bean, and the entomologist, Dr. H. H. King, the former dealing with soil analysis, gum production, hashish and native poisons, and the latter treating of the insects destructive to crops, mosquito control and the relation of birds to insects. Experiments in exterminating mosquitoes in irrigation ditches by a small minnow of similar habit to "Millions" of the Barbados, known as *Cyprinodon dispar*, have been successful. Other biological papers deal with the mosquitoes, birds and scorpions of the region.

The anthropological interests are represented by an account of the ancient gold mines of the Sudan by Mr. S. C. Dunn, gov-

ernment geologist. The Turin papyrus (14th century B.C.) describes these mines and is accompanied by the oldest maps in existence. The cult of the Nyakang and the divine kings of the Shilluk peoples are investigated by Dr. C. G. Seligmann. The king is killed when old age or sickness threatens. Captain Anderson gives an interesting analysis of the tribal customs in their relation to medicine and morals of the Nyam Nyam and Goor peoples of the upper Sudan.

These two volumes are full of varied information, much of it of great interest and promise of permanent value. It is magnificently suggestive in its portrayal of the warfare of science on the firing line of civilization and full of incentive to the reserves at the rear.

CHARLES ATWOOD KOFOID

UNIVERSITY OF CALIFORNIA

A History of the Birds of Colorado. By WILLIAM LUTLEY SCLATER, M.A. (Oxon.), M.B.O.U., Hon. M.A.O.U. (lately Director of the Colorado College Museum). With 17 plates and a map. Witherby & Co., 326 High Holborn, London. 1912. 8vo. Pp. xxiv + 576. For United States, \$5. Edition limited to 550 copies.

This is a well-planned and thoroughly up-to-date manual of the birds of Colorado, printed on light-weight paper, and, though a bulky volume of 600 pages, is easy and comfortable to handle. The work is based primarily on the collection of Colorado birds formed by Mr. C. E. Aiken during the last thirty-five years, recently acquired by the late General William J. Palmer and presented by him to the Museum of Colorado College, of which the author of the present book was recently for some years the director.

The introduction deals briefly with the physical features of Colorado, and contains an analysis of its bird fauna, with (1) respect to the season of occurrence of the species and (2) their distribution in the state with respect to altitude. Of the 392 species thus far recorded, about 17 per cent. are resident throughout the year, while the summer resi-

dents form about 30 per cent., the remainder being transient visitors in winter, spring and fall, of which about 106 species are of merely casual occurrence, with only from one to half a dozen records within the state for each.

The nomenclature and classification adopted conform to the third edition of the A. O. U. Checklist, which renders unnecessary the citation of original references for the genera and species. The author has also adopted a concise method of citing the Colorado references under each species, where the name of the author, an abbreviated date and a page reference direct the reader to the full title and place of publication of the paper given in the bibliography near the close of the volume (pp. 532-551), which mentions every publication of importance relating to Colorado ornithology up to December, 1910. This is followed by a gazetteer of the localities specially mentioned (pp. 553-562). With the keys to the higher groups, genera and species, the very satisfactory descriptions, the notes on distribution and habits, the author has succeeded in providing an admirable handbook of Colorado ornithology. Although there are here and there a few minor slips, the work bears the earmarks of a practised hand, and shows a thorough mastery of the subject, although the author's sojourn in Colorado was a comparatively brief one and his personal experience with Colorado birds thus necessarily limited.

The work is dedicated to his friend and patron, the late General Palmer, whose portrait forms the frontispiece of the volume. The half-tone plates illustrate the nesting habits of a number of interesting species, from photographs by well-known Colorado ornithologists. A contour map shows the principal streams, the counties and county-seats of the state, and indicates on a small scale the diversity of altitude and physical features.

J. A. A.

BOTANICAL NOTES

THE GARDEN IN EDUCATION

DORA WILLIAMS has done a good thing in writing a little book on "Gardens and their Meaning" (Ginn), and doing it in such an at-

tractive way that its reading is certain to accomplish what the author desired, namely, "to show the importance of science in the use of spade and hoe, and to urge that a garden for education may be, not merely in substance, but in spirit, a corner of the great world." A serial citation of the headings of the thirteen chapters will develop the topic, while at the same time giving the substance of the author's message. Thus we find headings as follows: What Makes a School Worth While? Little Studies in Cooperation; Situation and Soil; Plotting and Planning; A Word for Good Tools; Planting; The Art of Making Things Grow; Just How; Garden Foes and Garden Friends; Side Shows; New Life in Old Subjects; The Young Farmer's Almanac; The New Agriculture. The reader who knows something of the place of the garden in education can easily fill in most of these chapter headings, but few can do it in such enthusiastic words and such a genuine spirit of helpfulness and helpfulness. Her closing sentence may well be quoted as giving the purpose of the book:

Gardening, then, worked out at school after some such plan as has been sketched in these pages, will be a powerful lever to raise agriculture—rightly viewed the most rewarding of occupations—from the humble plane, where it has long remained, to the heights which it is destined to command.

The book is evidently designed for adults and the older only of the school children. It should be widely read and discussed in the "reading circles," especially those composed of earnest teachers, where it should do much good. One is tempted to suggest that the author should now write a complementary book for the children, a difficult task, but one for which she appears to be well fitted.

AN ISLAND FLORA

ABOUT seven years ago the California Academy of Sciences sent a scientific expedition to the Galapagos Islands (300 to 600 miles west of Ecuador), one of the incidents of which was an eleven days' visit to Cocos Island about midway between Costa Rica and the archipel-

ago. The botanical results of this visit are now published by Alban Stewart, botanist to the expedition,¹ which has just appeared under date of January, 1912.

The island includes between eight to ten square miles and rises often abruptly from the water, culminating in a mountain cone 2,788 feet high, evidently volcanic, but now heavily covered with a dense vegetation. The rainfall is abundant, and the temperature ranges from 68° to 92° F. Near the shore are coconut trees, but no mangroves, "possibly because of the absence of quiet bays and lagoons."

The interior of the island is covered for the most part with rain forests, in which the vegetation is usually so dense that even at midday, with the sun shining, the light is almost as diffuse as at twilight.

The trees are large and tall, reaching a hundred feet or more. "The largest and probably the most important tree from an economic standpoint is one which bears the common name of 'Ironwood'" of which there are trees on the island "so large that timbers $3 \times 3 \times 60$ feet could be cut from them."

In summing up the results of his study of the vegetation of the island the author says:

The flora of Cocos, like that of the Galapagos Islands, is distinctly that of an oceanic island. The relatively large number of ferns, the much smaller number of species in the remaining families, and the total number of species found on the island lend support to this view. The flora is probably of much more recent origin than is that of the Galapagos Islands. . . . It seems possible that the time that has elapsed since conditions on the island were suitable for the growth of higher vegetation has not been sufficient to stock the island by the slow process of seed dissemination, over considerable areas of water, with as many species as it is capable of supporting. The small number of endemic species on the island might also point to a relatively recent origin of its flora.

SYSTEMATIC NOTES

It is a hopeful sign that from time to time Professor Schaffner brings out papers on the

¹ *Proc. Calif. Acad. Sci.*, 4th series, Vol. 1.

classification of plants, the last of which appeared in the *Ohio Naturalist* for December, 1911. In this he reviews and rearranges some of his previous schemes, and adds a synopsis of the phyla, classes and subclasses of the whole vegetable kingdom. In the latter he recognizes fifteen phyla, viz: Schizophyta, Myxophyta, Zygomphyta, Gonidiophyta, Phaeophyta, Rhodophyta, Charophyta, Mycophyta, Bryophyta, Ptenophyta, Calamophyta, Lepidophyta, Cycadophyta, Strobilophyta, Anthophyta. The discussion contains a statement of principles, one of which may well be reproduced here:

In a word, the whole scheme of classification must show the result which has come about through progressive evolution, segregation, degradation and specialization.

Another paper by Henry Pittier on "New or Noteworthy Plants from Colombia and Central America," in the *Contrib. U. S. Natl. Herb.*, Vol. 13, pt. 12, among other things contains a revision of the Artocarpoideae-Olmediae of the family *Moraceae* which will interest critical systematists. Many good plates and text figures add much to the value of the paper.

In part 1 of Vol. 16 of the same Contributions, we find a critical discussion by W. R. Maxon, of the systematic standing of a Rocky Mountain fern known as *Asplenium andrewsii*, which may turn out to be an Americanized form of the European *A. adiantum-nigrum*.

Accompanying the foregoing is a "Report on a Collection of Plants from the Pinacate Region of Sonora," by J. N. Rose and P. C. Standley, in which are given the botanical results of an expedition from the Desert Laboratory at Tucson in 1907, into a region never before visited by a botanical collector. "The botanical collections, although small, have proved to be most interesting." Eighty-four species are enumerated, of which eleven are here described as new to science. Eight of the plants in the list are Monocotyledons, of which seven are grasses. Ten are Cactaceae, while seventeen are Compositae. The fine plates add greatly to the interest of the paper.

Dr. E. L. Greene continues in *Leaflets* (Vol. II., pp. 165-196) the publication of new species from different parts of the country, much space being given to new species of *Apocynum*, of which upwards of forty species are recognized that hitherto have found place under *A. cannabinum* and *A. androsaemifolium*. Half a dozen new species of *Trautvetteria* and five of *Erigeron* complete the fascicle.

Brief notice may be made here of the "Outline Key of the Groups of the Genus *Helianthus* in Michigan," by Mr. S. Alexander, in the Nineteenth Report of the Michigan Academy of Sciences (1911), in which the author brings together for publication some results of his critical studies of these plants in the field and under cultivation. Although incomplete, the paper contains many hints that systematic botanists may well heed.

Dr. A. Nelson's "New Plants from Idaho," in the *Botanical Gazette* for October, 1911, adds a number of new species from southwestern Idaho, a region as yet little known botanically.

Wm. R. Maxon describes (Smithsonian Miscellaneous Collections, Vol. 56, No. 24) "A Remarkable New Fern from Panama," a species of *Polypodium* in which the sori become crowded out so as to appear marginal upon the leaflets. To this species he has given the name *P. podocarpum*, and the hint is thrown out that it may constitute "a distinct generic type."

In M. A. Howe's Phycological Studies, V., in the *Torrey Bulletin* for November, 1911, he publishes a list of nine Chlorophyceae, seven Phaeophyceae, and twelve Rhodophyceae from Lower California, of which eight are new.

From the Institut de Botanique, Université de Geneve, the fifth and sixth fascicles (1910, 1911) contain the usual variety of contributions, ranging from morphology to physiology, pathology and the systematic botany of lower and higher plants, as, a new *Rhamnus*, the green snow of an Alpine

glacier (due to *Ankistrodesmus vireti*), the copulation of *Spirogyra*, the physiological rôle of catalase, a new blue-green alga, etc.

The well-known Minnesota Botanical Studies have begun to appear again, the second part of Vol. IV. bearing date of September 15, 1911. Its four articles are "Observations on the Morphology of the Underground Stems of *Symplocarpus* and *Lysichiton*," by C. O. Rosendahl; "Some Effects of Severe Frost upon Vegetation in a Condition of Active Growth," by F. K. Butters and C. O. Rosendahl; "Notes on the Species of *Liagora* and *Galaxaura* of the Central Pacific," by F. K. Butters; "Nova Fungorum Coloradensium Genera," by F. E. Clements, the last including six new genera of Sphaeriaceae. With this part are given title-page, table of contents and index of Volume III.

PATHOLOGICAL NOTES

DR. C. W. EDGERTON's papers "Two New Fig Diseases" (*Phytopathology*, February, 1911), "Diseases of the Fig Tree and Fruit" (Bull. 126, La. Expt. Station, March, 1911), "The Red Rot of Sugar Cane" (Bull. 133, La. Expt. Station, December, 1911), "*Botryosphaeria* on Cotton Bolls" (*Mycologia*, January, 1912), and "Flower Infection with Cotton Boll Rots" (*Phytopathology*, February, 1912), show that botanical activity in the south is bringing good results.

The same thing is shown by J. R. Johnston's "History and Cause of the Cocoanut Bud-Rot" (Bull. 228, Bureau of Plant Industry, U. S. Dept. Agric., February, 1912), dealing with "a very destructive and widespread disease of cocoanuts which has been known to occur in Cuba for more than thirty years." The bulletin is the result of investigations in Cuba, Jamaica, Trinidad and British Guiana, covering a period of four years. The remarkable discovery was made that the organism causing this bud-rot is the common *Bacillus coli*, and "it is believed that birds and insects are the carriers of this disease," but to this the author cautiously adds "the subject requires further study."

MYCOLOGICAL NOTES

THREE papers of much more than usual value in such a publication are found in the *Transactions of the Wisconsin Academy of Sciences, Arts and Letters* (Vol. XVI., Part II., No. 4). The first, by E. M. Gilbert, is entitled "Studies on the Tremellineae of Wisconsin" and includes notes upon twenty-one species belonging to nine genera. Apparently this systematic paper is preliminary to "a further physiological and cytological study of the group." The second paper, "Spore Formation in *Geoglossum glabrum* Pers.," by Hallie D. M. Jolivet, is a careful study of the formation of ascospores, with especial reference to the behavior and significance of the rays of the polar aster. Three fine plates accompany the paper. The longest paper is that by B. F. Lutman, entitled "Some Contributions to the Life History and Cytology of the Smuts." In it the author has reinvestigated the spore-formation and germination of species of smuts belonging to the genera *Ustilago*, *Doassansia*, *Urocystis* and *Entyloma* and compared them with *Tilletia* and other well-known genera. He finds that two groups of smuts may be distinguished—"the *Ustilago* group," and "the *Tilletia*, *Entyloma*, *Urocystis* division," which, he says, "may be more distantly related than has been commonly supposed." These he characterizes as follows: (1) *Ustilago* group, "simple spores produced by the breaking up of the mycelium; intercellular mycelium without haustoria; typically four-celled promycelium"; (2) *Tilletia*, *Entyloma*, *Urocystis* group, spores borne on lateral branches; haustoria; binucleated cells and non-septate promycelium. Eight good plates accompany the paper.

PALEOBOTANICAL NOTES

A CONCISE statement of one portion of paleobotany is given by Dr. J. M. Coulter in the February number (1912) of the *Popular Science Monthly*, accompanied by a helpful chart showing the relationships of the Cycadofli-

cales, Cordaitales, Benettitales, Cycadales, Ginkgoales, Coniferales and Gnetales.

The same author and Dr. W. J. S. Land published in the *Botanical Gazette* (June, 1911) a short paper (with two plates) on "An American *Lepidostrobus*" in which the structure of a fragment of a well-preserved cone is described from the central Iowa coal measures. This appears to be the first description of an American *Lepidostrobus* cone.

In a pungent note "On the True Nature of the Cretaceous Plant *Ophioglossum granulatum* Heer" in the *Annals of Botany* (October, 1911) Dr. M. C. Stopes shows that instead of being an *Ophioglossum*, the specimen from the Amboy clays is that of a staminate pine cone, and in proof of this conclusion she figures four pollen grains showing the characteristic wings!

An enumeration of the titles of some of the many papers published in recent years by the well-known paleobotanist G. R. Wieland may be helpful to botanical readers who are interested in this portion of botany, and especially in the method of discovery. Thus in the March, April and May numbers of the *American Journal of Science* for 1889 there appeared, under the general title, "Study of Some American Fossil Cycads," papers on "The Male Flower of Cycadeoidea," "Leaf Structure of Cycadeoidea," and "The Female Fructification of Cycadeoidea," showing that at that time he had made much progress in unraveling the puzzle of the old Cycads. Again later (March, 1900) in his paper on the "Yale Collection of Fossil Cycads" (*Yale Scientific Monthly*) he comes so near to the solution that he finds macrosporangia and microsporangia on the same trunk. Then in a fourth paper under the general title of "Study of Some American Fossil Cycads" he returns again (*Am. Jour. Sci.*, June, 1901) to the microsporangiate fructification of Cycadeoidea, and now makes out the structure of the old *Cycad* flower with its ovulate central cone surrounded by a whorl of pinnate stamens! Later came "The Proembryo of the Bennettiteae" (*Am. Jour. Sci.*, December, 1904); "Historic Fossil Cycads" (*Am. Jour. Sci.*,

February, 1908); "Paleobotany" (reviews in *Am. Jour. Sci.*, April, 1908); "The *Williamsonias* of the Mixteca Alta" (*Bot. Gaz.*, December, 1909); "Further Notes on Seed Structures" (*Am. Jour. Sci.*, August, 1911); "The Williamsonian Tribe" (*Am. Jour. Sci.*, December, 1911), and "The Smaller Flowerbuds of Cycadeoidea" (*Am. Jour. Sci.*, February, 1912). In the last is ample confirmation of the author's interpretation of the old Cycad flower structure as announced by him nearly eleven years earlier. These papers, with the author's monumental volume, "American Fossil Cycads" (1906) constitute a remarkable example of the gradual uncovering of facts and their successful interpretation, and combination into a consistent phylogenetic scheme.

CHARLES E. BESSEY

THE UNIVERSITY OF NEBRASKA

SPECIAL ARTICLES

THE INEFFICIENCY OF WIRES AS A MEANS OF CURING DEFECTIVE ACOUSTICS OF AUDITORIUMS

IN the popular mind, one of the first aids for a hall with poor acoustics is to install a system of wires or strings with the expectation that in some way the defect will be cured. This prevalent idea is doubtless due to the fact that there are many halls where wires have been strung, and people naturally conclude that there must be some merit in the method. As a matter of fact, this popular impression does not seem to be well founded, for the author has inspected a number of halls thus treated, and has found no marked improvement in the acoustics.

Thus in Dr. Parkhurst's church in New York City where a thin network of silk fibers of large mesh was stretched horizontally about half way between the floor and the dome, there still persisted a reverberation and an echo. In the Royal Cathedral in Berlin, a number of silk cords are installed in a horizontal network, yet the acoustics remain very defective. A fishnet is stretched near the ceiling in one of the court rooms of the Berlin Rathhaus

with no benefit to the acoustical properties. The Royal Albert Hall in London has a series of wires installed, and, while the acoustics there are improved, other features than wires have unquestionably produced the effect. The warden of a church in Nottingham, England, writes:

Several dodges were tried to overcome the (acoustical) defect, such as stretching wires across the nave.

And so on for other cases that might be cited.

The conclusions of the author in regard to the inefficiency of wires have not always been in accord with the opinions of the auditors in the various halls mentioned. The janitor of Dr. Parkhurst's church, in answer to the question, "Does the net help the acoustics?" replied, "Some says it does, and some says it don't." In the Royal Cathedral in Berlin, according to the attendant's account, the Kaiser thought the wires produced no improvement while the Kaiserin thought they did. The direct question to the attendant as to his own opinion proved very embarrassing and brought only a shrug of the shoulders. Later conversation, however, revealed his conviction that no help had been rendered. In the majority of cases where opinions were asked for, there was a decided expression against the use of wires—"the acoustics are as bad as before," "The wires have not helped," etc.

Some people, however, claim that the method is advantageous, and that the acoustics are really benefited. The author believes these claims are sincere, but attributes the better hearing to other features than the wires. For instance, the acoustics are usually improved when a large audience is present. Also, the opening of windows produces a good effect. Furthermore, regular attendants in a hall with poor acoustics get used to the defect, and, by an adjustment of the attention, are able in some cases to subordinate the disturbing factors and hear better than before. Thus on one occasion the author fixed his attention on a particularly strong echo and was able to hear more distinctly than by listening to the words

as they came directly from the speaker. On another occasion in this same hall the leader of the band had great trouble in conducting a certain selection. The piece being played was a xylophone solo with orchestra accompaniment. After some time the leader discovered that he was beating time to the *echo* of the xylophone. The players near the soloist kept proper time, the others near the leader played in unison with the echo. The result may be imagined.

While both observation and opinion indicate that acoustical defects are not helped by wires, it is interesting to look for further confirmation from the standpoint of theory. It is well known that if a loud tone is sung near a piano, certain wires of the latter will re-sound. Perhaps this phenomenon suggested the use of wires in auditoriums, with the hope that the objectionable sound would be absorbed or broken up in some way. But the conditions for the response of the piano strings are very favorable. There are many wires tuned to different pitches, so that certain ones are in tune, or nearly so, with any tone sung, and these are the wires that re-sound. The wire in the auditorium would respond therefore to only one of the many tones present. To be effective on this score, there would have to be many wires tuned so as to cover a wide range of pitch. Secondly, the piano wire is backed by a sounding board, which absorbs considerable energy and communicates it to the wire. The response is thus very much greater than it would be without the sounding board. The wire in the auditorium has no such sounding board, therefore it absorbs less energy and has less effect on the sound. Finally, the piano occupies a considerable portion of the space of the room and gets energy not only directly, but also by reflection from the near-by walls and ceiling. On the other hand, the wire in the auditorium is small, and is struck by only a small part of the sound waves, direct or reflected, hence has a small chance to help matters. All of these considerations indicate the smallness of the effect to be expected.

One other way in which wires might be beneficial lies in the possible scattering of the

sound waves. Here again, however, the small bulk of the wires allows but little effect. The sound waves pass around the wires in much the same way that large water waves on a pond pass by a stake projecting through the surface. It is only when the obstacle has some size compared with the waves that a disturbance is set up. If there were a large number of wires close together, the sound waves would be influenced. In halls, we find usually only a few wires installed, probably with the idea of having them inconspicuous.

From the various considerations mentioned, it is seen that the installation of wires in halls having poor acoustics is without marked effect. While much remains to be done on the problem of architectural acoustics, and though the means of cure can not be specified readily for each case, it is nevertheless of value to know that the installation of wires, as now used, will *not* serve to cure the trouble.

COLOR VARIATIONS OF THE HOUSE MOUSE IN CALIFORNIA

WHILE trapping for mice in the vicinity of Palo Alto, California, in November, 1910, a mouse was taken the under parts of which were colored white, as in the common Gambel's mouse (*Peromyscus maniculatus gambeli*), but which on examination, proved to be a house mouse (*Mus musculus*). Since that time, trapping in a number of localities in California by the author and others and search through previously made collections of California mammals have brought to light a considerable number of instances of color variations in the house mouse. So far, only a start has been made in the study of these variations. The meager results at hand are published at this time because the author is leaving California. It is hoped that such publication will direct the attention of students and collectors to the house mouse, an animal that is commonly neglected. Very likely further variations will be found in the same animal from other parts of America.

I am indebted to Professor J. O. Snyder, of Stanford University, and to Professor Joseph Grinnell, of the Museum of Vertebrate Zoology, University of California, for suggestions and for the use of the collections under their charge. To Miss Hilda Hempl, of Stanford University, I am indebted for a considerable number of specimens.

The common house mouse is nearly uniform in color all over. The under parts are a little lighter than the back, but the transition is very gradual. The entire color of the mouse is subject to some variation, both individual and geographic. No attempt will be made here to discuss this variation which affects all parts of the mouse equally or nearly so. We will consider only those variations in color which result in one part of the mouse becoming strikingly different in color from the other parts.

A considerable number of house mice in California have the under parts separated in color from the upper parts. The upper parts retain the color of the common house mice of the region, while the under parts become colored either white, creamy buff, reddish buff, or intermediate tints between these colors and the color of the under parts of the unmodified house mouse. These colors of the under parts, where present, are sharply separated from the color of the back and sides at a definite line. In about half the specimens this line is emphasized by the addition of a narrow stripe of pale fulvous.

In all, seven house mice with white under parts, two with creamy buff under parts and a much larger number with reddish buff under parts have been taken up to the present time. Enough intermediate stages between the various colors have been found so that it becomes certain that these grade into one another and therefore are probably the product of the same factor or factors of variation. What these factors are we can make no attempt to consider with the amount of data at hand. All attempts to correlate these color variations with cranial or bodily differences have been fruitless.

One peculiar specimen shows an oval white spot about one half inch long on the middle of the belly. In every other case noted the whole of the under parts are affected alike. The area covered by the modified color—except in this one instance—is just about the same as the area covered by the white in the common white-footed mouse (*Peromyscus maniculatus gambeli*).

The earliest record of any variation in the color of the ventral surface of the house mouse of California is furnished by a specimen in the Stanford University Museum collected April 3, 1893, by J. M. Stowell at Palo Alto. This specimen shows reddish-buff under parts sharply marked off from the color of the back. During November of 1907, Joseph Dixon took two specimens with white underparts and one with creamy buff under parts at Palo Alto. All other records of specimens with peculiar coloration are for the fall of 1910 and the spring of 1911.

A large proportion of the mice showing the color variations on which this article is based have been taken at Palo Alto and Stanford University. Here a few were found on the salt marshes near San Francisco Bay and the rest in the houses and barns at Palo Alto and on the campus of the university. In some houses all the mice seem to be more or less modified in color, though not all in the same way or to the same degree. In other places most of the mice may have the typical house mouse coloration and only a few show any variation. From a lot of fifteen mice taken in two days at Stanford University, only one showed any considerable variation and this one was white on the belly. Nearly half the mice taken in the region show some modification of the color of the underparts. Besides the region about Palo Alto, house mice showing variation in the color of the under parts have been taken during 1911 at Tipton, Tulare County, at Madera, Madera County, and at Pacific Grove, Monterey County. Of two house mice taken at Tipton, one shows a light creamy-buff ventral surface, while the other has the ordinary coloration of the house mouse. Of eleven house mice taken at Madera in a

barn and along the Fresno River, four had the under parts a dusky white sharply marked off from the color of the upperparts. The other seven had either no modification in color or the modification was very slight. Of four house mice examined at Pacific Grove, three showed pale reddish buff underparts and the other showed no modification. Two house mice taken at Pismo, San Luis Obispo County, and about fifty taken at Tracy, San Joaquin County, showed no modification. I know of no record of this color modification outside of the state of California.

Besides the modification of the color of the ventral surface, two specimens of house mice from California show the assumption of the dark longitudinal dorsal stripe described by Allen for *Mus musculus jalapa*. One of these specimens is from New River, Salton Sea, collected by Frank Stephens, and shows a wide dark dorsal stripe with no modification of the ventral surface. Another house mouse from the same locality taken at the same time does not have any indication of the dorsal stripe. The other specimen of the *jalapa* type is from Madera, Madera County, and in addition to a narrow dark dorsal stripe, has dusky white underparts sharply marked off from the color of the sides so that the color of both back and belly is modified.

These instances seem to indicate that the house mouse is undergoing modification in some localities, and it may be that important results will be obtained by the study of the progress of this modification.

SOCIETIES AND ACADEMIES

THE SECOND ANNUAL MEETING OF THE PACIFIC ASSOCIATION OF SCIENTIFIC SOCIETIES

THE second annual meeting of the Pacific Association of Scientific Societies was held at Stanford University, Friday and Saturday, April 5 and 6, 1912. Eight of the eleven constituent societies held sessions: Technical Society of the Pacific, the Cordilleran Section of the Geological Society of America, the Seismological Society of America, Pacific Coast Branch of the American Historical

Association, the Pacific Slope Association of Economic Entomologists, Pacific Coast Paleontological Society, Biological Society of the Pacific Coast and the California Section of the American Chemical Society. The other societies were either unable to hold or not desirous of holding sessions at this meeting. With the association met also the San Francisco Section of the American Mathematical Society.

The Astronomical Society of the Pacific was elected to membership in the association. This makes the association represent a membership of over 2,000 persons.

The officers of the executive committee elected for 1912-13 are Otto von Geldern, chairman; George D. Louderback, vice-chairman and J. N. Bowman, secretary-treasurer.

Berkeley was selected as the suggested place for the third annual meeting in 1913; and the suggested time was temporarily placed in the spring of that year—the definite date is to be determined later.

The general session of the association was held on Saturday evening in the chapel of the university. In the absence of President Jordan, Dr. Branner, vice-president, gave the address of welcome. Director William Wallace Campbell, of the Lick Observatory, gave an address on "Recent Studies of the Stellar System." He gave the latest views and theories as based on the observations and work done at Mount Hamilton and elsewhere. Professor Ewald Flügel, of Stanford University, read a paper on "Scientific Lexicography," wherein he traced the lexicographical work from the thirteenth century to the present; he discussed the standards that were used by the Grimm brothers in their work, and which formed the basis of all the later activity in lexicography and raised this subject to the rank of a science. Professor Andrew Cowper Lawson, of the University of California, gave the last address of the session on "Recent Views on the Archæan Rocks of Canada." Twenty years ago he examined these rocks for the Canadian government. Lately his findings and views have been brought into question. Last summer he went over the field again, at the instance of the Canadian government, with the result that he is led to corroborate his former findings and views.

THE BUILDING OF "CORAL" REEFS

A coral reef is a ridge or mound of limestone, the upper surface of which lies or lay at the time of its formation, near the level of the sea, and is predominantly composed of calcium carbonate secreted by organisms, of which the most important are corals.

THE above is the opening sentence of an able and suggestive paper by Dr. Thomas Wayland Vaughan on "Physical Conditions under which Paleozoic Coral Reefs were formed," published last year in the *Bulletin of the Geological Society of America*.¹ If we pass over for the moment the question as to just what is meant by "near the level of the sea," a point that is discussed by Dr. Vaughan later on, the part of the above definition that particularly challenges attention is the final clause, "of which the most important are corals." It is not to be denied that this last statement embodies the long-standing and still prevalent view as to the origin and composition of coral reefs and, in fact, it might seem at first sight to be quite axiomatic that corals should be the most important constructive agents in the formation of "coral" reefs. But in view of the fact that some rather recent studies indicate that lime-secreting plants have been much more important than the corals in the formation of certain "true coral reefs" and in view of the few borings and analytical studies of so-called "coral" reefs thus far made, there would seem to be sufficient ground for contending that the whole question as to the relative general importance of lime-secreting animals and lime-secreting plants in the formation of reefs is still an open one. From

MSS. intended for publication and books, etc., intended for review should be sent to the Editor of SCIENCE, Garrison-on-Hudson, N. Y.

¹ Vol. 22, p. 238.

what may be observed to-day in the tropics as to the relative abundance of calcareous marine plants and calcareous marine animals and from what has been determined by the study of the cores obtained by boring into coral reefs, it would appear that sometimes the plants predominate and sometimes the animals. As Dr. Vaughan points out, there are good grounds for believing that the conditions attending the formation of coral reefs in ancient times were not very different from those that prevail at present. In any event, the definition quoted above is intended to be a general one and its validity is to be tested by application to recent and modern conditions as well as to those of long-past geological ages.

The best-known example of a thorough and detailed study of the nature of a coral reef is embodied in a quarto work of more than four hundred pages published by the Royal Society of London in 1904 and entitled "The Atoll of Funafuti: Borings into a Coral Reef and its Results: Being the Report of the Coral Reef Committee of the Royal Society." Funafuti was selected for this study because it was considered a "typical" coral reef or island. Several borings were made by members of the three successive expeditions that visited the atoll, the first attempts being only partially successful, and the cores thus obtained were brought back to England for careful study. The main boring was finally driven down to a depth of 1,114½ feet. *Lithothamnion*, a hard stone-like red coralline seaweed, of the group commonly known to zoologists and geologists as "nullipores," was found to be more or less abundant through the entire length of the boring; *Halimeda*, a calcified green seaweed, was locally very abundant from 28 to 1,096 feet in depth. Professor J. W.

Judd sums up the general results of the analysis of the cores as follows:

Dr. Hinde's carefully drawn up lists show that from top to bottom the same organisms occur, sometimes plants, sometimes foraminifera, and sometimes corals predominating (p. 174).

It is to be observed that he mentions plants first. Moreover, Mr. A. E. Finckh, who was one of the members of the expedition and wrote the chapter on "Biology of Reef-forming Organisms at Funafuti Atoll," definitely groups these organisms in order of their reef-building importance as follows: "(1) *Lithothamnion*; (2) *Halimeda*; (3) the Foraminifera; (4) the Corals." It will be noted that the first two places in this ranking are given to members of the plant kingdom and that the corals, the "most important" reef-building organisms of Vaughan's definition and of the still prevalent popular belief, are relegated to a fourth position. This naturally raises the somewhat academic, though chiefly biologic, question, "When is a 'true coral reef' not a coral reef?" It raises also a serious question as to whether the continued use of "coral" reef for structures that have been built up largely through the agency of plants is not responsible for false ideas and widespread mental confusion.

That the opinion of Mr. Finckh in regard to Funafuti is not his alone, is evident from the following statement by J. Stanley Gardiner, who, being a professor of zoology in Cambridge University, should be free from any suspicion of bias in favor of the plants:

The reef [of Funafuti] seems to have been mainly formed by the growth of nullipores, which are now building up masses outside the rim and adding them on the reef, causing its extension seawards.²

²"The Coral Reefs of Funafuti, Rotuma and Fiji, together with some Notes on the Structure

Incidentally, for the benefit of botanists, who have long abandoned the term "nullipore," even though the enforcement of priority principles in nomenclature may possibly lead to its revival, it may be explained that the generic name *Nullipora*, as proposed by Lamarek in 1801, was made to include four species of calcareous organisms believed by him to be animals, but all of which, probably, were plants and members of the family Corallinaceæ of the red algæ—the family popularly known as the "coralline seaweeds." Furthermore, they were of the subgroup sometimes spoken of as the "unsegmented" corallines, including the numerous forms that until recently have passed under the widely inclusive generic name *Lithothamnion*, but now commonly segregated into smaller generic groups known as *Lithothamnion*, *Lithophyllum*, *Goniolithon*, *Phymatolithon*, etc. But the term "nullipore," which has remained the almost exclusive possession of the zoologists and geologists, while applied chiefly and properly to the stone-like or coral-like red algæ, has occasionally been made to cover also undoubted animals and was used by Alexander Agassiz³ to include also some of the very different calcified green algæ. Alexander Agassiz, by the way, was one of the first to emphasize the importance of "nullipores" in reef-building, but the loose way in which he frequently referred to "nullipores and algæ," "corallines and algæ" may easily have hidden from many of his non-botanical readers the fact that his "nullipores" and "corallines" were just as truly algæ as are any of the species of *Fucus*.

But, to return to our main subject, there is considerable evidence that the dominance

and Formation of Coral Reefs in General," *Proc. Camb. Philos. Soc.*, Vol. 9, pp. 417-503, 1898.

³ *Bull. Mus. Comp. Zool. Harv. Coll.*, Vol. 14, p. 82, 1888.

of plants in building up the "true coral island" Funafuti is not an exceptional or isolated instance of their activity in this direction. Professor Gardiner, in describing the reefs of Fiji, in the paper referred to above, says:

The parts of "compact homogeneous texture" are very numerous and are formed, I believe, mainly by carbonate of lime secreted by incrusting nullipores. The importance of the incrusting nullipores, in the formation of the reefs of the Central Pacific can not be overestimated.⁴

Again,⁵ in discussing the foundation of atolls in general, Professor Gardiner remarks that

The chief building organism is *Lithothamnion*, the bathymetrical zone of which must be limited to a large degree by the extent to which light can penetrate seawater.

In another case,

This nullipore [*Lithophyllum craspedium*], Finckh says, is actually the reef-former at Onoatua [Gilbert Islands]. He saw no live coral there, but everywhere on the lagoon and ocean-face immense masses of this particular nullipore.⁶

That lime-secreting plants rather than corals are sometimes, at least, the dominant reef-formers in the Indian Ocean as well as the Pacific, is shown by the following remark by Professor Gardiner:

The reefs of the Chagos are in no way peculiar, save in their extraordinary paucity of animal life. . . . However, this barrenness is amply compensated for by the enormous quantity of nullipores (*Lithothamnion*, etc.) incrusting, massive, mammillated, columnar and branching. The outgrowing seaward edges of the reefs are practically formed by their growths and it is not too much to say that, were it not for the abundance and large masses of these organisms, there would be no atolls with surface reefs in the Chagos.⁷

That the coralline algæ form extensive banks and reefs in the Dutch East Indies also is indicated by the following quotation from Mme. A. Weber-van Bosse's report on "The Corallinaceæ of the Siboga Expedition":⁸

Near the coast of Haingsisi, an island near the S. W. point of Timor, the Siboga anchored twice . . . ; the second time good luck favoured us, it was springtide, the water sank very low and we could observe that the whole reef . . . consisted chiefly of *Lithothamnion erubescens* f. *Haingsisiana*. It was remarkable that the branching knolls remained quite dry during several hours of the day, exposed to the glare of the tropical sun, and that this seemed not to injure them. . . . This *Lithothamnion*-bank struck me, because it is such a unique sight to see the ground, as far as the eye can reach, covered by the pretty beautifully pink-coloured knolls, which are heaped up so close together that, while walking, one crushes them continually, making a peculiar noise as of broken china. We encountered, however, other and perhaps more instructive *Lithothamnion* banks during our voyage.

Bermuda, as is generally known, was commonly considered a "true coral" island until the studies of Alexander Agassiz⁹ and of Henry B. Bigelow¹⁰ indicated that the corals have played a rather minor part in its upbuilding. Dr. Bigelow believes (*loc. cit.*, p. 582) that "algæ probably form the greatest mass" of what he terms the "shell sands" of Bermuda, and it is of interest to note that Sir John Murray in reporting the results of the *Challenger* Expedition intimates that the calcareous seaweeds and their broken down fragments were the dominating elements in three out of four analyzed samples of so-called "coral" sand or mud from Ber-

muda. Dr. Bigelow, in connection with his critical studies of "The Shoal-water Deposits of the Bermuda Banks," made a series of dredgings on the Challenger Bank, nine miles or more from Bermuda. His dredge brought up chiefly "calcareous pebbles," which on examination proved to be formed by a species of *Lithothamnion*. These were growing at a depth of from 30-50 fathoms, a depth too great for most of the corals. In summing up the results of these studies, Dr. Bigelow writes:¹¹

The dredgings from the Challenger Bank add to the evidence already accumulated to prove the great importance of the nullipores as reef builders. . . . This process taking place over the Challenger Bank, where there is no direct evidence of either elevation or subsidence, has raised it to within some thirty to fifty fathoms of the surface of the sea, a depth where a few corals already flourish. If we imagine this process as continuing until the bank rises to within about twenty fathoms of the surface, we should then have excellent conditions for the formation of a coral reef. Of course in such upbuilding the nullipores constitute only a part, though a most important one, of the whole growth.

It would appear from this observation of Dr. Bigelow's and from various other records that the lime-secreting seaweeds flourish and are effective reef-builders in greater depths than is the case with the corals. Dr. Vaughan, in the paper under discussion, quotes Professor J. Stanley Gardiner as authority for the statement that the "nullipores extend to a depth of 35 fathoms" in the Maldives, but Mr. A. E. Finckh in his dredging operations about Funafuti frequently found them in "depths of over 100 fathoms *in situ*"¹² and also found *Halimeda* alive down to 45 fathoms. From Alexander Agassiz's description of the Pourtales Plateau off the southern coast of Florida, one seems justified in inferring that he found incrusting

"nullipores" in a living condition at depths of from 250 to 350 fathoms.¹³ According to Dr. Vaughan, it is generally conceded "that 25 fathoms is the greatest depth" at which the reef-building corals work effectively, "although an occasional reef species may extend downward to a depth of 40 fathoms."

Besides flourishing in greater depths than the corals, the lime-secreting seaweeds are much less dependent upon high temperatures than are the corals. Sir John Murray has remarked¹⁴ that "in the polar seas and in the cold water of the deep seas there is, as is well known, a feeble development of all carbonate of lime structures in marine organisms," a statement that may be true enough in a comparative way for organic nature as a whole, but is manifestly much more true of the corals than of the coral-like red algæ. The coral-line algæ are, locally at least, abundant from 73½° south latitude¹⁵ to 79° 56' north latitude.¹⁶ The late Professor Kjellman, of Upsala, has stated¹⁷ that off the coasts of Spitzbergen and Nova Zembla *Lithothamnion glaciale* "covers the bottom in deep layers for several miles" mostly in 10 to 20 fathoms of water, and he adds that "in the formation of future strata of the earth's crust in these regions it must become of essential importance." Another species of *Lithothamnion* is said to form banks on the coasts of Iceland and of Greenland. Foslie¹⁸ states also that

North of the polar circle on the coast of Norway banks have been met with which cover the bottom for several miles and plants appear in immense masses, frequently representing only one species.

A good account of "Algæ as Rock-building Organisms," with special reference to their occurrence in ancient limestones, was contributed to *Science Progress*¹⁹ in 1894 by Professor A. C. Seward, of Cambridge University. An interesting feature of Professor Seward's paper is his summary of the results of J. Walther's studies of a *Lithothamnion* bank in the Bay of Naples about 30 m. below the surface of the water:

By action of the percolating water the *Lithothamnion* structure is gradually obliterated, and the calcareous mass becomes a structureless limestone. Walther applies his knowledge of this recent algal deposit to the examination of a Tertiary "Nulliporenkalk" near Syracuse. In many parts of this formation there occur well-preserved specimens of *Lithothamnion*, but in others a gradual obliteration is observed of all plant structures until the rock becomes entirely structureless. A similar instance of structureless limestone is described from the Lias of Todten Gebirges [Todten Gebirge].

In Bermuda, southern Florida and the West Indies one finds among the living reef-building organisms and in their distribution and association many of the general types described by Gardiner and others for the Pacific and Indian oceans, even though "true atolls" of the Pacific type may be rare or quite wanting. There are banks and reefs that appear to consist almost wholly of calcareous plants others that are almost "pure stands" of corals, and yet others where these two elements are intermingled. In the last case, the "nullipores" often seem to be overgrowing and smothering the corals, as has been observed in the Pacific and elsewhere. In view of all of the evidence now available it would be a bold man who would venture to say

¹⁹ Vol. 2, pp. 10-26.

that the corals are secreting and depositing any more calcium carbonate in the West Indian region than are the calcareous algæ. The massive beds of *Halimeda opuntia* off the Florida Keys (the same species, by the way, that is filling the lagoons of some of the South Sea atolls) are striking, as are the banks of *Goniolithon strictum* in the Bahamas and reefs of *Lithophyllum Antillarum* and *Lithophyllum daedaleum* along the shores of Porto Rico, yet probably none of these are so conspicuous and massive as are certain local aggregations of living corals in the same general regions. However, the lime-secreting plants appear to be much more generally and widely distributed, both horizontally and vertically, than are the corals, and the rate of growth is, of course, a factor of importance in any attempt to estimate the relative lime-depositing activity of corals and calcareous algæ. The notable studies and measurements of living corals by Dr. Vaughan at the Tortugas station of the Department of Marine Biology of the Carnegie Institution of Washington are beginning to throw a most welcome light on the rate of growth of the corals. No similar records of the rate of growth of the calcareous red algæ have as yet been published, so far as we are aware, but from the fact that these plants often cover and smother living corals one is perhaps justified in assuming that the growth of certain kinds of coralline algæ is superficially, at least, more rapid than that of certain kinds of corals. For the rate of growth of the calcareous green algæ we have scarcely any definite records except one by Finckh,²⁰ who observed in Funafuti a radio-vertical growth of three inches in six weeks in a tangle of *Halimeda opuntia* that had found its way through a hole in a board. This growth-rate, which is possibly more than a fair general average for the

species, seems much more rapid than any thus far attributed to the corals.

With the dominance in reef-building activities resting sometimes with the calcareous algæ and sometimes with the corals, and with the Foraminifera and other groups also playing their parts, the problem of determining the "most important" constructive element in the calcium carbonate reefs of the world, ancient and modern, is naturally a most complicated and difficult one and one that may never be solved to the full satisfaction of those most interested. Alexander Agassiz, in 1894, in summing up the general result of his explorations of Bermuda and the Bahamas, which had revealed a condition of things not realized before, frankly remarked that it was a "significant example of how little we as yet know of the history of the formation of the coral reefs."²¹ As a general proposition this remark seems almost as apt now as when it was made in 1894. However, since the day of the first illuminating borings into the "true coral atoll" of Funafuti, much evidence has accumulated tending to show that the importance of the corals in reef-building has been much over-estimated and that the final honors in this connection may yet go to the more humble lime-secreting plants.

NEW YORK BOTANICAL GARDEN

UNIVERSITY CONTROL

II

IN a review of the different factors concerned with the administration of a university the corporation in ultimate control is the natural starting-point. It was becoming that the fellows of Yale College, a collegiate school primarily for the education of the clergy, should be representative.

²¹ *Bull. Mus. Comp. Zool. Harvard Coll.*, Vol. 26, p. 278.

²⁰ "The Atoll of Funafuti," p. 146.

clergymen of the state. In general the trustees of the primitive American college were competent to administer its simple economy. But even then there were difficulties. Before the American Institute of Instruction meeting in Worcester, Mass., in 1837, the Rev. Jasper Adams, president of Charleston College, gave a lecture on "The relations subsisting between the board of trustees and the faculty of the university," stating that as far as he knew this had never been the subject of special investigation. He argues that the trustees should manage the funds of their institution, while the faculty should regulate the courses of instruction and the internal administration: Professors should be appointed by the trustees on the advice of and in accordance with the wishes of the faculty. It appears that in those days there was trouble through the trustees interfering with what the faculties regarded as their rights, notably at Hamilton College, concerning which the president wrote a pamphlet entitled "A Narrative of the Embarrassments and Decline of Hamilton College," which he attributed to meddling by the trustees with the business of the faculty. At that time President Adams and President Davis seem to have regarded themselves as professors rather than as trustees. According to President Adams:

More than one board of trustees has ruined, and every board will ruin its college, which shall interfere with the province rendered appropriate to the faculty by the peculiar skill, knowledge and experience which their education, greater attention to the subject, and practical opportunities, have naturally, and as a matter of course, given them. . . . Many a faculty of a college, who felt themselves qualified, not only to sustain their institution, but to raise it to usefulness and renown, and gain for it the favor, confidence and patronage of the public, have found all their efforts discouraged, embarrassed and finally defeated by the conduct of their board of trustees. Plans of improvement, after having been matured by much

labor and careful consideration, have been presented for acceptance and approbation, only to be retained with coldness and indifference, treated with neglect and finally rejected, after a hasty examination, for want of a competency to understand them. Favorable times and seasons have been permitted to pass by unimproved, and have been lost never to return, because the faculty had not power to act on the subject, and the trustees could not be induced to seize the favorable moment, and turn the occasion to the benefit of the institution. Under these circumstances, the faculty have been compelled to remain inactive, and let things take their course, or to resign their office in discouragement and disgust. In either case, the institution has been ruined.

The legal powers of trustees and regents are similar everywhere, but their actual part in the conduct of the institution varies greatly. It is likely to be larger when the board is small and when the members reside near by. In his Harris lectures on "University Administration" President Eliot says: "The best number of members for a university's principal board is seven," and with pleasing naïveté he adds a little later: "It is a curious fact that the university with the most fortunate organization in the country is the oldest university, the principal governing board, the President and Fellows of Harvard College, consisting of seven men." When the board of trustees is large and meets but rarely, there is usually an executive committee which with the president is in substantial control. The members of this committee are likely to be the friends and adherents of the president—in practise the president is likely to select the trustees and the members of their executive committee—and the faculties and professors are supposed to communicate with the trustees only through the president. Under our existing system, there should be an elected committee of the faculties which would meet with the executive committee of the trustees. It would in addition be advis-

able to permit the professors and other officers to elect for limited terms representatives—not necessarily from among themselves—on the board of trustees in the manner now becoming usual for alumni representation. It is undesirable for the individual professor to tease the trustees with his needs or grievances; but there should surely be some way by which trustees and professors can consider together the problems confronting the university. A joint committee of trustees and professors such as has just now been constituted to administer the Crocker Cancer Research Fund of Columbia University is an excellent plan.

If trustees are trustees and not directors, it does not greatly matter in practise how many of them there are or how they are chosen, so long as they are men of integrity and honor, representative of the common sense of the community. Even if the trusteeship is an acknowledgment of gifts made or hoped for, no great harm is done. But a self-perpetuating board with absolute powers, even though for a generation the powers may not be abused or even used, is intolerable in a democratic community. The president and directors of industrial corporations are elected by the shareholders and are increasingly supervised by the state. In the state universities the regents are elected by the people or appointed by their representatives, and the people may be regarded as the ultimate corporation. In the case of the private universities, it would apparently be wise to have a large corporation consisting of the professors and other officers of the university, the alumni who maintain their interest in the institution and members of the community who ally themselves with it. This corporation—or perhaps better the three groups of which it is composed—should elect the trustees. Thus there might be a board of

nine trustees, one being elected annually for a three-year period by each of the three divisions of the corporation.

Several of my correspondents hold that the members of the community permitted to join the corporation of a university should be carefully selected. I should myself like to see the widest possible participation. If 10,000 or 50,000 people would join such a corporation, so much the better. They would pay dues, perhaps five or ten dollars a year, and would enjoy certain privileges such as attendance at lectures and concerts, the use of libraries, museums, rooms for meetings and the like. If many people are concerned with their university, it is well for them and for it. Some of them will become seriously interested, ready to aid with their counsel, their influence and their money. In New York City several institutions—the Metropolitan Museum of Art, the American Museum of Natural History, the Zoological Park, the Botanical Garden—are partly supported by the city, partly by boards of trustees and partly by members. The buildings are owned and the curators are paid by the city; the collections are owned and the research work is paid for by the trustees; the members have certain privileges in return for dues. In spite of obvious difficulties, the plan has worked well.

A large corporation holding the university in trust for all the people is clearly a step in the direction of public ownership. It is the ultimate fate of every corporation to be controlled by the state, and our private universities will surely become part of the system of public education. This should develop gradually rather than through such measures as have been required to obtain control of church property in other nations. When the people own their universities they will probably see the wisdom of delegating to those con-

cerned—namely, the officers of the university, its alumni and members of the community taking an interest in higher education and having knowledge of it—the right to elect the trustees. True democracy does not consist of government by the uninformed, but of government by those most competent, selected by and responsible to the people. In one of the leading state universities one third of the trustees are elected by the alumni; a second third might to advantage be elected by the teachers, the remaining third being elected by the people or their representatives.

When trustees in the state universities are elected by the people or their representatives and in the private universities are elected by the corporation consisting of officers of the university, alumni and members of the community, the question as to their powers and duties is perplexing. Much can be said in favor of giving them no more power than is vested in a trust company designated as trustee of an estate, and arguments can be urged in favor of a small paid board of experts having the ultimate decision on all questions. I seem to have been almost the only educational person in the country who approved of the principle of Mayor Gaynor's plan for a small paid board of education for New York City, and I should regard its present adoption as risky. This, however, is the correct method of democracy—experts selected by the people and paid for their work. The professors and other officers of the university should be such. Whether in addition to them it is desirable or necessary to have a board to coordinate and control their work, to regulate their duties and fix their salaries, is a question which can only be settled by experience. Certainly the commission form of government is preferable to an individual autocrat.

In the academic jungle the president is my black beast. I may seem to be in the condition of the animal suffering from the complication of diseases described in a recent issue of a New England paper:

Patrolman Lindstrum went to East Elm Street recently and shot an alleged mad dog. The dog also was declared to have hydrophobia and rabies.

As a matter of fact neither barking nor biting is warranted. An eminent philosopher of Harvard University in a lecture to a class at Radcliffe is alleged to have depicted in eloquent terms the darkness of the life of him who has lost his religious faith and then to have added that the only compensation is a sense of humor. Whereat first one and then another of the students began to weep until all the eighty girls were in tears. It is more becoming for university professors to appreciate the semi-humorous absurdity of the situation than to fall to weeping together. I once incited one of my children to call her doll Mr. President, on the esoteric ground that he would lie in any position in which he was placed. Of course, the president is by nature as truthful, honorable and kind as the rest of us, and is likely to have more ability or enterprise, or both. But he really finds himself in an impossible situation. His despotism is only tempered by resignation; and in the meanwhile he must act as though he were a statue of himself erected by public subscription. In Tennyson's words:

Who should be king save him who makes us free.

The argument for giving a free hand to the president is that this is the way to get things done. It should, however, be remembered that it is quite as important—and this holds especially in the university—not to do the wrong thing as it is to do the right thing. The time of the president is largely occupied with trying to correct or to explain the mistakes he has made, and the time of the professor is too much

taken up with trying to dissuade the president from doing unwise things or in making the best of them after they have been done. Administrative details should be attended to promptly and correctly; this is the proper business of secretaries and clerks. Then we need leaders, most of all in a democracy. But in a democracy leaders are the men we follow, not the men who drive us. In the university each should lead in accordance with his ability and character.

The trouble in the case of the university president is that he is not a leader, but a boss. He is selected by and is responsible to a body practically outside the university, which in the private corporations is responsible to nobody. In our political organization, the mayor, governor or president has great power, too great in my opinion, if only because it demoralizes the legislature; but they are responsible to the people who elect them. I object even more to the irresponsibility of the university president than to his excessive powers. The demoralization that the president works in the university is not limited to his own office; it has given us the department-store system, the existing exhibit of sub-bosses—deans, heads of departments, presidential committees, professors appointed by, with salaries determined by, and on occasion dismissed by, the president, all subject to him and dependent on his favor.

It is not my wish to depreciate unfairly the services of the American university president. Like the promoter in business and the boss in politics, he has doubtless been a factor natural and perhaps desirable in a given stage of evolution, when the growth of the complexity of society and the need of new adjustments have outrun the adaptability of the individual. It is probable that the president has increased appropri-

ations and gifts; it is possible that he has promoted rather than hindered the development of the university and the extension of its work. The president, however, has not usually been the cause of gifts, professors and students, but only the means of diverting them from one institution to another, and on occasion of doing so in ways unworthy of the institution which he then misrepresents. The president has not infrequently sacrificed education to the fancied advantage of his own institution. Thus college entrance requirements have imposed studies in the high school which drive from it the majority of boys. The opposition of certain presidents of proprietary universities to a national university is not less pernicious, if it results from honest prejudice. The prestige of the president is due to the growth of the university, not conversely. He is like the icon carried with the Russian army and credited with its victories. President Eliot claimed that he had never asked for a gift for Harvard. During the lean years he was regarded as a poor money-getter; when the fat years came with the increasing wealth of the alumni and of the country, this opinion was reversed, but he had not changed. President Eliot is a truly great man, but his remarks on all sorts of subjects, usually wise but occasionally otherwise, were reported everywhere, not for their wisdom, but on account of his position.

While I regard it as desirable to do what little I can to make ridiculous an institution which has become a nuisance, and while I should find my state of dependence on a president for my opportunity to serve the university intolerable if I concealed my views, I certainly do not wish to be understood as lacking in appreciation of the fine characters and high motives of most of the men who have served

as professors and later become presidents. They do not considerably, if at all, excel in character or ability beyond the average standard of the professorship, but they exploit before the world how high this standard is. The practise of many presidents is a sacrifice of their real convictions to the imagined exigencies of the situation. Most of them would agree that autocracy in the university is undesirable. Thus President Eliot writes:

The president of a university should never exercise an autocratic or one-man power. He should be often an inventing and animating force, and often a leader; but not a ruler or autocrat. His success will be due more to powers of exposition and persuasion combined with persistent industry, than to any force of will or habit of command. Indeed, one-man power is always objectionable in a university, whether lodged in president, secretary of the trustees, dean or head of department.

Dr. Seelye, then president of Smith College, at the inauguration of Dr. Rhees as president of Rochester University, said:

Autocracy, however, is a hazardous expedient, and is likely to prove ultimately as pernicious in a college as it is in a state. It induces too great reliance upon the distinctive characteristics of a despot, and too little upon those of a gentleman. One-man power is apt to enfeeble or to alienate those who are subject to it. . . . Successful autocrats are few, and however long their term of service, it is short compared with the life of an institution. If they leave as an inheritance a spirit which has suppressed free inquiry, and which has made it difficult to secure and retain teachers of strong personality, the loss will probably be greater than any apparent gain which may have come through the rapid achievements of a Napoleonic policy.

Under existing conditions—at least in our proprietary universities—it appears that the place which the president now fills, or wobbles about in, might be divided into three parts. There might be a chancellor, as in the English universities, a man of influence and of prominence, representing the corporation and the relations of

the institution to the community, concerned with increasing the endowment and prestige of the university. Then there might be a rector, as in the German universities, elected annually or for some other limited period by and from the faculties, presiding at academic functions and the like. In the third place, there would be a secretary or curator, an educational expert in charge of administrative details. In a real democracy and with a people appreciative of the needs and service of the university, the former two officials would become superfluous.

It must be admitted that the situation is difficult. The alumni are no longer predominantly scholars or even professional men. They have more concern for football than for the work of the professor; any university club could get on better without its library than without its bar. But the alumni of a university should be not less intelligent and wise than the electorate of the nation. In both cases the ultimate control must be democratic, unless perchance we are following false gods. Experts and intellectuals are not, as a rule, to be trusted to act for the common good in preference to their personal interests. The professors of an endowed university can not be given the ultimate control. A monastery or a proprietary medical school must ultimately be reformed from without. We need the referendum and the recall because we can not trust those placed in authority, and we fear these measures because we do not trust the people. An aristocracy is deaf; a democracy is blind. But it is our business to do the best we can under the existing conditions of human nature. Advancing democracy has burned its bridges behind it. No one believes that a city should be owned by a small self-perpetuating board of trustees who would appoint a dictator to run it, to decide what

people could live there, what work they must do and what incomes they should have. Why should a university be conducted in that way?

The bible is often misquoted to the effect that "money is the root of all evil." The love of money and the lack of money are indeed factors in most of the difficulties of society. Next after the getting of men, the getting of money for the university is its most troublesome problem, and next after the proper treatment of men, the use of money is the most important question. He who holds the purse strings holds the reins of power. That the president should decide which professor shall be discharged and which have his salary advanced, which department or line of work shall be favored or crippled, is the most sinister side of our present system of university administration, more pernicious in the private universities, where dismissals and salaries are kept secret, than in the state universities, where salaries are published and teachers are, or should be, dismissed, as in the better public-school systems, only after definite charges.

To transfer the control of appointments and finances from the president to the professors would strike many as passing from purgatory to a worse place. A university executive said to me the other day that if the professors were in control the first thing that they would do would be to raise their own salaries. Well, perhaps worse things have been done. It may be admitted that this is what a president usually does for himself and to an extent beyond the dreams of the most avaricious professor. But there are at least two points of difference. First, the president may increase his salary by withholding a small sum from each professor, whereas the professors could only increase their salaries by obtaining the money for the purpose. Second, it is un-

desirable for a president to receive three or four times the salary of the greatest scholar or teacher on the faculty, as is the case at California, Columbia and other institutions. It is subversive of decent social and educational ideals for the president of Harvard University to be permitted to build on the grounds of the university a house for himself costing \$100,000, and for the trustees of Columbia University to build for their president a house which with its grounds may cost twice that amount. But it would be in the interest of the university and of society if the salaries of professors were increased. Abuses are possible, but at present whatever makes the academic career more attractive to men of genius is in the interest of all the people.

The undeniable difficulties in the way of adjusting salaries and the conflicting needs of schools and departments, whether the decision rests primarily with the president, the trustees or a committee of the faculties, may be minimized by permanence of tenure and fixed salaries, and by giving the departments financial autonomy. President Van Hise, of the University of Wisconsin, and President Butler, of Columbia University, have recently pronounced in favor of the competitive system in the university. The former says: "There is no possible excuse for retaining in the staff of a university an inefficient man." The latter says: "A teacher who can not give to the institution which maintains him common loyalty and the kind of service which loyalty implies ought not to be retained through fear of clamor or criticism," and further in respect to equality of salaries: "In my judgment such a policy would fill the university with mediocrities and render it impossible to make that special provision for distinction and for genius which the trustees ought always to be able to make."

There are advantages in a system of severe competition for large prizes under honorable conditions, as well as in permanent tenure of office with small salaries and a free life; but confusion and harm result from running with the hare and hunting with the hounds. If there is to be competition in order to retain university chairs, then the university must be prepared to forego able men or to compete with other professions in the rewards it gives. It must offer prizes commensurate with those of engineering, medicine and law, namely, salaries as large as from ten to a hundred thousand dollars a year. It is further true that under these circumstances a man must be judged by his peers. A university which dismisses professors when the president thinks that they are inefficient or lacking in loyalty to him is parasitic on the great academic traditions of the past and of other nations. A single university which acts in this way will in the end obtain a faculty consisting of a few adventurers, a few sycophants and a crowd of mediocrities. If all universities adopt such a policy, while retaining their present meager salaries and systems of autocratic control, then able men will not embark on such ill-starred ships. They will carry forward scientific work in connection with industry and will attract as apprentices those competent to learn the ways of research.

Permanent tenure of office for the professor is not a unique state of privilege. A president's wife has permanent tenure of office; he can not dismiss her because he regards her as inefficient or because he prefers another woman. Analogous social conditions make it undesirable that he should have power to dismiss a professor for similar reasons. In the army and navy, in the highest courts, to a certain extent in the civil service of every country, there is

permanence of office. Indeed it is nowhere completely disregarded; service is always a valid claim for continued employment. A wife may be divorced by the courts, an army officer may be court-martialed, a judge may be impeached; but such actions are taken only after definite charges and opportunity for defence. Permanent tenure of office is intended to improve the service, not to demoralize it. It is attached to honorable offices, where public spirit and self-sacrifice are demanded, and the wages do not measure the performance. In Germany, France and Great Britain the permanence of tenure has given dignity and honor to the university chair, attracting to it the ablest men and setting them free to do their work.

Incentive to the best work of which a man is capable is not excluded from the university if the professorship itself is made a high reward, the essentials of which are permanence, freedom and honor. Men who have proved their ability for research need opportunity rather than extraneous stimulus. Still it is true that while the lack of prizes does not considerably dampen the spirit of research, it makes the academic career less attractive to those who should be drawn to it. Most of the graduate students in our universities are men of mediocre ability, drifting along with the aid of fellowships and underpaid assistantships to an inglorious Ph.D. and a profession with meager rewards. Several of my correspondents write that if large income, power and honor were not attached to the presidency, there would be no prize to attract men to university work. From my point of view it is altogether demoralizing that the reward held before the investigator and teacher should be the position of an executive, politician and promoter, which takes him away from the higher work for which he is fit. It is a curious

exposure of the situation when the president of our largest university can write:

Almost without exception the men who to-day occupy the most conspicuous positions in the United States have worked their way up, by their own ability, from very humble beginnings. The heads of the great universities were every one of them not long ago humble and poorly compensated teachers.¹⁴

It would be well if some universities would maintain professorships so highly rewarded and regarded that the possibility of a call would exercise a beneficial influence throughout the country, and if each university would establish from one to ten professorships having a salary and a prestige equal at least to that of the presidency. Vacancies in these professorships should be filled by cooptation or election by the faculties or by a faculty committee; but even under the present system of presidential nominations, it would be better to have a few important appointments made publicly than a number of small increases in salary made secretly as the result of presidential favor.

I venture to supplement my argument by quoting from an address¹⁵ made ten years ago, which seems less radical now than then, since socialism has ceased to be a nightmare for respectable citizens, since pensions have become general, since Harvard has adopted the plan of equal salaries with increments of \$500 after each five years of service, since Senator Villas has made provision at the University of Wisconsin for super-professorships, since the president of a university is no longer sacrosanct. The paragraph reads:

"'The American as he is,' by President Nicholas Murray Butler.

¹⁴ Read before the members of Phi Beta Kappa of the Johns Hopkins University, on May 2, 1902, and printed in *The Popular Science Monthly* for June, 1902.

The university is those who teach and those who learn and the work they do. The progress of the university depends on bringing to it the best men and leading them to do the best work. Our president, Mr. Remsen, in his admirable inaugural address, told us that the chief function of the university president is to find the right man, and his chief difficulty the lack of enough such men to go round. He considered the question of how far an increased salary would add to the supply of good men. I quite agree with Mr. Remsen that a professor will do about the same kind of work whether his salary is \$4,000 or \$10,000. If anywhere, in the university it should be to each according to his needs, from each according to his ability. The professor who must live in a city or who has children to educate should be given the necessary income. He should have an adequate pension in old age or in case of disablement; the university should insure his life in a sufficient sum to provide an income for his wife and minor children. The professorial chair can be made attractive by freedom, responsibility and dignity, rather than by a large salary. Still it must be remembered that we live in a commercial age, and men are esteemed in accordance with their incomes. While it may not, or at all events should not, matter greatly to the professor, it may be well for the community that those who do the most for it should be paid on the same scale as those of equal ability in other professions. It may not be necessary to double the salaries of all university men, but it would probably be desirable to have certain prizes that would represent to the crude imagination of the public the dignity of the office and would perhaps attract young men of ability. The average salaries of teachers are about the same as in the other professions, but there are no prizes corresponding to those in the other professions. A clergyman may become a bishop, a lawyer may become a judge, a physician may acquire a consulting practise; and they may earn incomes of from \$10,000 to \$100,000. A professor can only earn a large salary and an apparent promotion by becoming president of his university; and this I regard as unfortunate. As Mr. Remsen told us that the professor would be pleased, but not particularly improved, by an increase in salary, I may perhaps be permitted to suggest that a president might be pained, but would not be seriously injured, by a reduction of his salary to that of the professor. My preference in this matter would be for the professor to have a fixed salary—perhaps \$3,000 to \$6,000, according to the expense of living

in the neighborhood, with \$300 to \$600 subsidy for each of his children between the ages of 10 and 21. Advances in salary dependent on the favor of the authorities appear to be undesirable. If salaries must vary from \$3,000 to \$5,000, a man should be appointed at such salary as may be necessary, but should thereafter receive automatic increases, say of \$500 after each five years of service. Then there should be a few research chairs in each university, promotion to which would be a mark of distinction, and occupancy of which would dispense from all routine work and carry a salary equal to that of the presidency.

It is awkward to urge a reform, such as an increase in the salaries of professors or the advance of a few salaries to that of the presidency, when this would become superfluous or undesirable, if society as a whole could be reorganized on a just economic basis. Elsewhere¹⁰ I have discussed the question as follows:

The best reward for scholarly work is adequate recognition of the work as preparation for a career in life. At Columbia University a man takes his doctor's degree at the average age of 27 years. He is fortunate if he receives immediately an instructorship at \$1,000 a year; the increments of salary are \$100 a year for ten years, so that at the age of 37 he receives a salary of \$2,000. In a commercial community the imagination is not stirred by such figures. The university is a parasite on the scholarly impulse instead of a stimulus to it.

The first need of our universities and colleges is great men for teachers. In order that the best men may be drawn to the academic career, it must be attractive and honorable. The professorship was inherited by us as a high office which is now being lowered. Professors and scholars are not sufficiently free or sufficiently well paid, so there is a lack of men who deserve to be highly rewarded, and we are in danger of sliding down the lines of a vicious spiral, until we reach the stage where the professor and his scholarship are not respected because they are not respectable.

I should myself prefer to see the salaries, earnings and conveyings of others cut down rather than to have the salaries of professors greatly

increased. When a criminal lawyer—to use the more inclusive term for corporation lawyer—receives a single fee of \$800,000, our civilization is obviously complicated. Every professor who is as able as this lawyer and who does work more important for society can not be paid a million dollars a year. But neither is it necessary to pay him so little that he can not do his work or educate his children. I recently excused myself somewhat awkwardly for not greeting promptly the wife of a colleague by saying that men could not be expected to recognize women because they changed their frocks. She replied: "The wives of professors don't." It is better to have wit than frocks; but in the long run they are likely to be found together.

The first step of a really great university president would be to refuse to accept a larger salary than is paid to the professors. The second step would be to make himself responsible to the faculty instead of holding each professor responsible to him. The bureaucratic or department-store system of university control is the disease which is now serious and may become fatal. This subjection of the individual to the machinery of administration and to the rack wage is but an invasion of the university by methods in business and in politics from which the whole country suffers. We may hope that it is only a temporary incident in the growth of material complexity beyond the powers of moral and intellectual control, and that man may soon regain his seat in the saddle.

I myself accept the social ideal: From each according to his ability, to each according to his needs; and I believe that, thanks to the applications of science, the resources of society are sufficient to provide adequately for all. But the first step to take in our present competitive system is to make rewards commensurate with effective ability and a compromise between services and needs. I have pointed out that, apart from exceptional cases, the range of individual differences in many traits is about as two to one. Thus in accuracy of perception and movement, in quickness of recognition and reaction, in rate of learning and retentiveness of memory, in time and variety of the association of ideas, in validity of judgments, I have

¹⁰ "The Case of Harvard College," an address before the Harvard Teachers' Association, *The Popular Science Monthly*, June, 1910.

found in laboratory experiments a range of difference of this magnitude. The able student can prepare a lesson or earn the doctor's degree in about half the time required by the poorer student. For the same kind of work and under similar conditions the value of the services of an individual varies within somewhat the same limits. A good laboring man or a good clerk is worth as much as two who are mediocre. The value of genius to the world is of course inestimable. A great man of science may contribute more than even the most successful promoter—a Rockefeller, a Carnegie or a Morgan—gets. But such contributions are made possible by the organization of society as a whole, and should in large measure be distributed among its members, preferably in the direction of making further contributions possible. Scientific men should receive adequate rewards, and the surplus wealth which directly or indirectly they have produced—it must be counted by the hundreds of thousands of millions of dollars—should, in so far as this can be done to advantage, be spent on further scientific research.

The available wealth in the United States and Great Britain suffices to provide a home and the tools of production for each family and the productivity of labor to provide an annual income of about \$1,000 for each producer. If waste in production and expenditure were reduced, even to the extent that now obtains among teachers and scientific men as a group, there would probably be available \$1,500 for each adult, including women engaged in the care of the home, or \$3,000 for each family. If this were distributed on a range of two to one in accordance with ability, the more deserving teachers and scientific men with their wives would earn salaries of \$4,000, in addition to owning their homes. An

addition of from \$250 to \$1,000 should be allowed for each child requiring support and education, to be deducted in part from the incomes of those having no children, and allowance should be made for the varying cost of living in the city or the country and the like.

If the maximum income of a university professor or scientific man with a family should be from \$5,000 to \$10,000, no one should receive more, except to cover greater risks. There is no occupation requiring rarer ability or more prolonged preliminary training, and there is none whose services to society are greater. If there are to be money prizes—incomes of \$20,000 or \$100,000 or more—then they should be open to professors and investigators. Scientific ability is as rare as executive or legal ability, and is far more valuable to society. The lawyer who receives a fee of \$800,000 for enabling a group of promoters to get ten times as much by evading the intent of the law, does not add to the wealth of society. The scientific man who increases the yield of the cereal crop by one per cent. adds \$10,000,000 a year to the wealth of the country and five times as much to the wealth of the world. The scientific man who discovered and those who have developed the Bessemer process of making steel have, according to the estimate of Abram S. Hewitt, added \$2,000,000,000 yearly to the world's wealth. There is no reason except the imperfect adjustments of society why the lawyer should receive large rewards and the scientific man a scant salary. Those who render services to an individual or group are likely to be paid in accordance with the value of their services to the individual or group; in our competitive system those who render services to society as a whole are not paid at all, or only partially and indirectly. Of our thousand leading men of science, 738 are employed in uni-

versities and colleges, 106 in the government service, 59 in research foundations. It is the duty of these institutions to provide adequately and liberally for their support and for their work.

The rewards of the academic and scientific career deserve detailed discussion because they are of fundamental importance to the university and to society. Professors and investigators should have adequate incomes, as large as is desirable for any social class, but above all they should have opportunity to lead a life free from distracting or dishonorable compromises. It should be emphasized that nothing here written is intended to promote a privileged class of university professors. Valparaiso University and Mr. Edison's Menlo Park Laboratory are useful, as well as Harvard University and the Rockefeller Institute for Medical Research. My concern is only that the university should be of the greatest possible service to the people and to the world. It may be that the great bulk of routine teaching and routine research can be done most economically under the factory system, with a manager to employ and discharge the instructional force and bosses to keep each gang up to a square day's work. But then the highest productive scholarship and creative research must find refuge elsewhere than in such a university.

It is truly distressing that our universities should be so conventional and unimaginative, each trying to follow the lead of those bigger than itself, all lacking in fineness and distinction. The Johns Hopkins, Clark, Stanford and Chicago were founded one after the other with promise of higher things, and each has relapsed into the common mediocrity. Harvard and Yale maintain the traditions of scholarship; the Johns Hopkins and Chicago have not abandoned the ideals of research; Columbia looms up with the vastness and

crudeness of the metropolis; the state universities exhibit the promise and the immaturity of our democracy. But each and all unite the scholasticism of the twelfth century with the commercial rawness of the twentieth century. Can there not be one university where the professor will have a study instead of an office, where the ideal set before the young instructor is something else than answering letters promptly and neatly on the typewriter, where men are weighed rather than counted, where efficiency and machinery are subordinated to the personality of great men? Could there not be a university or school, dominating some field of scholarship and research with its half-dozen professors and group of instructors and students drawn together by them? Might not means be devised by which the professor would be paid for the value of his teaching, service and research, and then be set free to do his work how and when and where he can do it best? It is not inconceivable that there should be a national or state university, with some features of the royal academies, rewarding with fellowships men of unusual promise and with professorships men of unusual performance, endowing the individual instead of the institution.

If it is not possible at present to have free professors and independent schools, we can at least strive for greater freedom of the individual and larger autonomy of the department within the university. As the position and salary of the professor should not depend on the favor of a president, so the department or school should be allowed substantial autonomy. There is nothing more disheartening to the members of a department or school than to have its activities prescribed or limited, its annual appropriation apportioned, by a centralized system. A great danger confronting the modern university is its own

bulk. In the evolution of organic life a limit is placed on the size which an animal can attain. Its surface increases more slowly than its mass, and there must be differentiation and division of labor in order that the animal may grow and react properly to the environment. Even then a limit is fixed; it is doubtful whether apart from the nervous system a structure more complicated than that of the mammal will be reached, or that animals much larger than man will survive. Only a polyp or similar creature can conduct a pure democracy; the organization of higher animals must be more complicated. The growth in size of the American university has been large and rapid. Faculty or town-meeting methods have become difficult or impossible; the institution drifts into autocratic and bureaucratic control. A representative or delegated system of government is necessary for the university, as a whole, but its divisions can maintain a family and democratic system.

President Eliot says¹⁷ that a long tenure of office will be an advantage to the president and to the university he serves, but that the chairman of departments should be chosen for short periods and should generally be junior or assistant professors to give them opportunity and because "dangers from the domination of masterful personages will be reduced to a minimum under this system." It is not evident why it is less desirable to limit "the domination of masterful personages" in the office of the president or of the dean than in the department. But it is true that a departmental autocracy may be even worse than one on a larger scale, and for the reason that it is conducted in the dark. A president may say that a teacher "ought not to be retained through fear of

clamor or criticism," but fortunately public opinion does prevent the more serious abuses to which the system is liable. In certain departments of certain universities instructors and junior professors are placed in a situation to which no decent domestic servant would submit. Clearly that is no breeding ground for genius and great personalities.

It can not be denied that the organization of the departments of a university is one of the difficult problems that confront us. The German plan, according to which the individual rather than the department is the unit, is in many ways preferable. But the American university conducts what is practically a secondary school in the first two years of the college, and it conducts professional schools which are not of university grade. The high schools and small colleges should take over the first two years of the college, establish schools of agriculture and of the mechanic arts, and conduct courses preparatory to medicine, law, engineering and teaching. In a large state, the state university would have one hundred thousand students, if it received all the young men and women between the ages of sixteen and twenty who should continue educational work. Such education should be provided locally and in connection with productive industry, as in the admirable plan adopted by the school of engineering of the University of Cincinnati, by which students work alternate weeks in the university and in the shop. Under President Eliot, Harvard placed both its college and its professional schools on a university basis; under President Lowell, it has moved backward in the direction of making the college a school of information and culture and of requiring the professional school to begin with the elements. To such an extent is the university the plaything of its president!

¹⁷ "University Administration."

For administrative and financial purposes it seems necessary to organize the university into schools, divisions or departments, although for educational purposes as much flexibility as possible should be maintained. The scope and size of such a division should depend on convenience and local conditions, rather than on logical distinctions among the subjects taught. A small college or a small medical school can be conducted to advantage under one faculty. In a large university there is no need to have a separate department for each of the oriental languages because they differ from one another more than do the European languages, though it may be desirable to have separate departments for German and French. When a medical school, or even the work in a special science, such as chemistry, becomes large, it may be advisable to organize it into partly autonomous divisions. There is no gain in economy and usually a loss in cooperation and effectiveness when the entering class of a college or professional school exceeds fifty or a hundred, and when its faculty exceeds twenty or thereabouts. Colleges should remain small; if a university must have a great crowd of college students, they should be divided among separate colleges, as in the English universities. These colleges should not, however, consist of freshmen, as President Lowell plans, or of students belonging to a certain social class, as is likely to happen under the fraternity and club system, but of men having common intellectual interests. Even small colleges for general education should aim to excel and to do research work in some special direction. In the large university the residential colleges and departments should coincide, so that younger men will join a group of older students and instructors having similar interests and ends in life. As I have elsewhere remarked:

The ideal is the zoological hall of the old Harvard, where apprentices of a great man and a great teacher lived together. This is told of again in the charming autobiography of Shaler. A boy from the aristocratic southern classes, with ample means and good abilities but no fixed interests, fell into this group. There he discovered his life work and pursued it with boundless enthusiasm. Nor did the fact that he devoted himself exclusively to professional work in natural history in college prevent him from writing Elizabethan plays in his old age. The number of men of distinction given to the world from this small Agassiz group is truly remarkable.

A group of some 10 to 20 instructors, having registered primarily under them from 50 to 200 students, is a good size for a school, division or department. Each can be well acquainted with the others and take a personal and intelligent interest in all the work of the department. At the same time the number is sufficient to permit the representation of diverse kinds of work and points-of view, and to make possible the election of officers and a democratic control. The chairman or head and an executive committee should of course be elected, not named by a semi-absentee president. In a group of this character questions are not usually brought to a vote. In reaching decisions each member is likely to be weighed as well as counted. In my experience the junior members of a faculty or department take too little rather than too much share in its discussions and its control. If they obtained constitutional rights they might become more aggressive; if they should, so much the better. One of the serious difficulties of the present system is that the younger men do not share in the conduct of the university and do not feel themselves to be part of its life. Those who do not have their ideas before they are thirty are not likely to have them. The paraphernalia and camp baggage of modern civilization have become so heavy that they threaten to block its further advance. If men must devote thirty years to mere

acquisition, and be kept even longer in official subjection, there is not much chance that they will do anything else thereafter. What youth can do should be joined with what age can know.

Voting rights in a department might be in proportion to the salary the officers receive; but such statutory regulations are scarcely needed. The real control is vested in the aggregate common sense of those concerned. The group may well be flexible in character. When courses of instruction and educational problems are under discussion assistants and even graduate students may be admitted to advantage. When the question is the promotion of an instructor, the group would naturally be limited to those of higher office. The chairmanship of the department might rotate among its members or the same head might be reelected continuously according to convenience. It by no means follows that the professor most eminent in research should be the executive head; on the contrary, it should usually be a man of competent administrative ability whose time is of less value. Every reasonable man believes in economy in administration and letting the men do things who can do them. Even the most important decisions can be left to the head of the department or its executive committee, so long as they represent and are responsible to the whole department.

The school or department should have complete control of its own educational work. So long as there is ample room for differences of opinion as to the value of different subjects and methods, it is well that there be variation and survival of the fit. Entrance requirements and degrees are among the chief obstacles to education. An instructor in Columbia University said recently to a student who had just received the highest grade assigned in the course:

"Why did you take the course, if you don't want a degree?" If there must be degrees, it may be necessary to standardize them; but this should be done only to the extent of prescribing the amount of work to be done in the direction called for by the degree, this being determined by the time spent, weighted in accordance with the ability of the student. I shall print shortly statistics in regard to all doctorates of philosophy granted in the sciences by American universities. For each department of each university will be given the percentage of doctors who continued to pursue scientific work and the percentage who attained a given degree of distinction. If any police regulation is needed, such publicity is far better than the examination of a candidate before the faculty, or the requirement of all sorts of qualifications.¹⁸

Financial as well as educational autonomy should be given to the school or de-

¹⁸ This paper is concerned with problems of administration, not with questions of teaching and research. The latter are by far the more important; indeed administrative methods are only of consequence in so far as they affect education within and without the university, research and the applications of knowledge. Incidentally I may remark that I should give the student the same freedom and the same democratic system that I should like to see the teacher enjoy. I should admit to the university any student and let him stay there so long as his presence did not do injury to others. I should let him choose his own work and his own methods of work; not because all kinds and methods of work are equally good, but because I regard myself as incompetent and most of my colleagues as even more incompetent to impose any system on the student. I should in large measure do away with grades, required attendance, required courses, required examinations and degrees, not because these things are not in some ways and in some cases useful, but because on the whole they do more damage than good. So far as possible, I should let students manage their own affairs, their dormitories, fraternities and athletics, their codes of manners and of morals.

partment. Its total income should be held as a trust fund, to be decreased only after full and public investigation. The laboratories, rooms, apparatus, equipment, library, etc., should be held in trust for the department, to be taken away against its will only for clear reasons and on the recommendation of a competent faculty committee. Under these conditions the members of a department will plan on a safe basis for the future, and will seek to increase its funds and facilities. I know of a case in which a professor obtained a gift of \$100,000, made expressly "to increase the facilities of the department," and the income was assigned by the president and trustees to pay the salary of that professor against his earnest protest. I also know of a case in which a department which had built up one of the strongest laboratories in the country had those of its rooms especially devoted to research taken away and given to a weak department, to induce a certain professor to accept a call from elsewhere to the headship of the weak department. These are of course extreme cases and might seem incredible, if it were not that interference with the vested rights of departments is of frequent occurrence.

The Harvard plan of visiting committees which may take an active interest in the educational work and financial support of departments is commendable. Under the existing trustee system it might be well if one trustee would concern himself especially with one or two departments, attending their meetings and doing what he could to advance their interests. There can to advantage be within the university departments related to its educational work, but under independent control. Thus the most useful and vigorous division of Columbia University, with the possible exception of the faculty of political science, is

the Teachers College, which is under its own trustees with a dean and faculty responsible to them. As a department of education under the trustees of Columbia College, it would probably have had no more leadership than the departments at Harvard or Yale. The educational alliance between Columbia University and the Union Theological Seminary is far better than a school of theology under the trustees of the university. There is no valid objection to two schools of law or two schools of chemistry, independently controlled, but enjoying the advantages of educational affiliation with a university. Endowed research institutions and municipal, state or governmental bureaus, can to advantage be placed near a university, contributing to and gaining from its educational work.

Appointments and the apportionment of funds are said to be questions insoluble under democratic control. But in spite of the difficulties the case is not so bad as autocratic one-man power. If there are fixed salaries with automatic increases, only three or four decisions must be made. Shall this man be appointed instructor? Shall he be appointed junior professor after five or ten years of service as instructor? Shall he be appointed full professor after five or ten years of service as junior professor? Who shall be appointed to super-professorships, if such exist? As a matter of fact under the existing system instructors and junior professors are nearly always nominated by the department or its head. They alone have the necessary information in regard to the men and the situation. The nomination of a full professor can be entrusted better to the department concerned than to a president. But such an appointment being for life and of immense consequence can not be too carefully guarded. It should be passed on by

a board or committee composed, say, of two members of the department, two members of allied departments and two distinguished representatives of the subject outside the university concerned. Such control would prevent undesirable inbreeding or the further deterioration of a weak department. Nominations should be made publicly—the English plan of definite candidates with printed records has much to commend it—and the power of veto should perhaps be given to the faculties as well as to the trustees.

The apportionment of the existing income of a department varies but little from year to year, and can safely be left to the department. Questions arise only when an increase which the department can not itself obtain is wanted, and there are general funds available, but not sufficient to supply all the needs of the university. Under the existing system each head of department grabs for everything in sight, and the president plays the part of an inscrutable and sometimes unscrupulous providence in the semi-secret distribution of his favors. No scheme could be more demoralizing. The correct plan is for each department to draw up its budget, with requests for increases and the reasons clearly indicated, the proposed budgets being printed and open to all concerned. Under these conditions unreasonable claims would not often be made by the departments. Plans for new departments and new lines of work could also be submitted by any responsible group. An elected committee of professors, with the assistance of an expert curator or controller, would then pass on the various budgets and proposals and adjust them to the available income, the reductions made by the committee being of course published. The budget for the university would then go to the trustees. It may be objected that under this

plan existing work would be strengthened rather than new ground broken. But might not this be better than the existing presidential mania for expansion? It seems in fact probable that if many professors and junior instructors were concerned, there would be more new ideas than when the initiative is left to a single man, and further that wise plans would be more likely to be adopted and inexpedient schemes to be rejected.

When schools and departments have autonomy, there is no need for much super-legislation and super-administration in the university. The machinery should be as simple as may be. Departments may be united into a school or college and elect a dean and a faculty or an executive committee to coordinate the work. A department can elect members to represent it in allied departments and on the faculties of the schools and colleges with whose work it is concerned. There should be an elected council or senate to represent the entire university and an executive committee which can confer with the executive committee of the trustees. There may at times to advantage be faculty meetings or plebiscites of large groups or of all the officers of the university. Questions concerning the entire university can be discussed to advantage by the fly-leaf method of the English universities, and a vote can be taken without a general assembly at a polling booth or by mail.

There are advantages and disadvantages in large faculty meetings. When all important matters are decided by administrative officers or executive committees and only trivial questions are discussed before the faculty, usually by certain polyphasic members, its meetings are likely to fall into disrepute. Men are efficient in direct proportion to their responsibility. Further, a body of men is effective inversely as its

size and directly as the time it works together. A body of fifty men such as the faculty to which I primarily belong, meeting for an hour three times a year, without power or responsibility, is clearly dedicated to futility. But if any one supposes that university presidents would do better under these conditions, he should call to mind the conduct of the trustees of the Carnegie Foundation. It seems to be the case that in order to make large faculties real legislative bodies, it would be necessary to devote more time to their meetings than is expedient, and perhaps more common sense than is available. All parliaments, congresses and legislatures do their work through cabinets and committees; but these are responsible to the whole body. Some such plan is necessary in the university. Still the cynical attitude toward faculty meetings common in academic circles appears to be one of the sinister symptoms resulting from the existing methods of autocratic control. It is typical of existing conditions that the most recent university school to be established—the School of Journalism of Columbia University—does not have a faculty but an “administrative board.” I belong to a club at the meetings of which each member must speak once and only once, not exceeding his share of the time, and the discussion is followed by a dinner. If faculty meetings could be made into educational and social clubs they would perform a useful function. The meetings of the faculty of arts and sciences at Harvard may give rise to complaints, but they have been of real service to the university.

Truth, openness, publicity, are the safeguards of free institutions. It is better to wash your dirty linen in public than to continue to wear it. The affairs of a university should be conducted in the full light of day. The proceedings of the trus-

tees, the discussions and conclusions of faculties and of committees, the activities of the president, the work of professors, salaries and the provisions of the budget, the appointment of officers and the rare cases in which it is necessary to dismiss a professor, should be open to all. Light is an excellent disinfectant; what is of more consequence, it is essential to healthy life and growth. “And God said, let there be light: and there was light. And God saw the light, that it was good.”

Several of my correspondents argue that if the control of a university were vested in its teachers, they would be distracted from their proper work of teaching and research. In a recent article¹⁹ on “The University President in the American Commonwealth,” President Eliot writes:

Most American professors of good quality would regard the imposition of duties concerning the selection of professors and other teachers, the election of the president, and the annual arrangement of the budget of the institution as a serious reduction in the attractiveness of the scholar's life and the professorial career.

Do President Eliot and the lesser presidents and the few professors who share their views believe that university professors and other citizens of a city should not concern themselves with municipal government or vote for a president of the nation? Are we of the world's greatest democracy and in the twentieth century to revert to the theory that the common people should do the daily work imposed on them, and trust to the king and his lords to care for them?

In the preface to the first edition (1906) of the “Biographical Directory of American Men of Science,” I wrote:

There scarcely exists among scientific men the recognition of common interest and the spirit of cooperation which would help to give science the place it should have in the community. It is fully

¹⁹ *The Educational Review*, November, 1911.

as important for the nation as for men of science that scientific work should be adequately recognized and supported. We are consequently in the fortunate position of knowing that whatever we do to promote our own interests is at the same time a service to the community and to the world.

Trade unions and organizations of professional men, in spite of occasional abuses, have been of benefit not only to those immediately concerned, but to society as a whole. President Eliot did not obtain commendation for calling the "scab" a hero. But if it is expedient to better the conditions under which work of any kind is done, this is of the utmost importance for education and research. If we can unite to improve the conditions of the academic career, so that it will attract the best men and permit them to do their best work, we make a contribution to the welfare of society which is permanent and universal. It may be that the time has now come when it is desirable and possible to form an association of professors of American universities, based on associations in the different universities, the objects of which would be to promote the interests of the universities and to advance higher education and research, with special reference to problems of administration and to the status of the professors and other officers of the university.

The space at my disposal is exhausted and many problems directly and indirectly concerned with the control of a university remain untouched. I am well aware that this paper is written in the spirit of the advocate and the reformer, rather than from the point of view of the judge and the responsible administrator. Against most of the suggestions which have been made valid objections may be urged. The only principle that I am prepared to defend whole-heartedly is that the university should be a democracy of scholars serving the larger democracy of which it is a part.

A government of laws is better than a government by men; but better than either is freedom controlled by public opinion and common sense, by precedent and good will. As that nation is happy which has no history, so that university is fortunate which has the least administration, and my most inclusive answer to the question how to administer a university is—don't.

J. McKEEN CATTELL

SCIENTIFIC NOTES AND NEWS

THE cost of preparing for publication the unfinished manuscripts left by the late Professor C. O. Whitman, together with that of the publication of the same in the best possible manner when ready, has been undertaken by the Carnegie Institution of Washington. Provision is also made for the maintenance of the large collection of pigeons, and for the current researches with them. Dr. Oscar Riddle, in charge of the work, has been appointed a research associate in the Carnegie Institution.

THE University of California has conferred the doctorate of laws on Dr. George E. Hale, director of the Solar Observatory of the Carnegie Institution, and on two of its graduates, Dr. Sidney E. Mezes, professor of philosophy and president of the University of Texas, and Dr. E. C. Sanford, professor of psychology and president of Clark College.

CAMBRIDGE UNIVERSITY will give the honorary doctorate of science to Major Leonard Darwin, lately president of the Royal Geographical Society.

THE University of Manchester will confer the degree of doctor of science on Dr. B. H. Scott, F.R.S., the distinguished botanist.

PROFESSOR NOCHT, director of the Tropical Institute at Hamburg, succeeds Professor Baelz as president of the German Tropical Society.

KING ALFONSO has given an audience at Madrid to Mr. Marconi, and has conferred on him the Grand Cross of the Order of Alfonso XII.

THE members of the Bureau of Chemistry have presented to Dr. H. W. Wiley, as a farewell gift, a chest containing 144 pieces of flat silver, a massive meat platter with side dishes, and a porringer, pap spoon and cup for Harvey W. Wiley, Jr., born on May 16. The plate on the mahogany chest is inscribed as follows: "To Harvey W. Wiley, whose leadership has been an inspiration to all who have had the privilege of knowing personally, day by day, the breadth and depth of his well-stored mind, his unshakable integrity and his splendid poise and never-failing geniality under any and all conditions. From the Bureau of Chemistry, U. S. Department of Agriculture, 1883-1912."

AN expedition for the further collections of fossil American horses for the Peabody Museum, Yale University, will be conducted this summer under the direction of Professor Richard S. Lull, associate curator in vertebrate paleontology. The party will explore in the Panhandle region of Texas and the banks of the Niobrara River in central Nebraska. Mr. Frederick Darby, one of the preparators in the Peabody Museum, and possibly one or two volunteers will accompany the expedition.

MR. A. E. PRATT, accompanied by his son, Mr. Felix B. Pratt, arrived in Piura, Peru, on May 3, direct from London *via* Barbados and Panama. They outfitted in Piura for the trip overland to Iquitos on the Upper Amazon. The object of the expedition is the collection of natural history specimens, chiefly butterflies, beetles and birds. The first sets go to a private collection and the rest to the British Museum of Natural History. Mr. Pratt and his son have spent three years in similar work in the interior of New Guinea, and have also worked in Australia, Madagascar and South America. They carry a full outfit and will proceed by way of Huancabamba, Jaen and the Marañon. From Iquitos they will follow the Amazons down to Pará, and thence back to England.

THE *Journal* of the American Medical Association states that the scientific investigations at Teneriffe have received a new exten-

sion by the erection of a station for observing anthropoid apes. Professor Rothmann, of Berlin, and Frau Professor Selenka, of Munich, have been sent to Teneriffe by the department of education to make preparations to this end, since it may be expected that in the uniformly warm climate there the animals may be kept in the open air through the entire year under the conditions of life that are natural to them.

MR. ARTHUR MAURICE HOCART has been elected to a senior scholarship at Exeter College, Oxford, for two years for the purpose of carrying out anthropological research in Fiji.

PROFESSOR JOSEPHINE E. TILDEN, of the University of Minnesota, has been given leave of absence on half salary, for the coming year, to carry on botanical research in the Islands of Tahiti and New Zealand.

PROFESSOR ARTHUR GORDON WEBSTER, of Clark University, sailed on the *Mauretania* on May 22 to take part as a delegate of the United States government in the Radio-Telegraphic Conference held in London in June, to represent Clark University at the quarter-millennial celebration of the Royal Society in July and to attend the International Congress of Mathematics at Cambridge in August. Professor Webster is one of the six Americans whose names appear on the international committee of the congress.

DR. WILLIAM H. F. ADDISON, of the medical department of the University of Pennsylvania, has sailed for Germany, to study with Professor Edinger at Frankfurt-am-Main.

T. POOLE MAYNARD, Ph.D. (Hopkins), has resigned as assistant state geologist, Geological Survey of Georgia, and will open an office as a consulting and mining geologist.

H. R. FULTON, associate professor of botany in the Pennsylvania State College and botanist in the station, has been appointed botanist and vegetable pathologist in the North Carolina College and Station.

DR. BERNHARD FITTIGE, associate professor of chemistry at Marburg, died on April 27, aged sixty-two years.

PROFESSOR F. O. GROVER, head of the department of botany in Oberlin College, has been appointed by the faculty to represent the college in the Ohio Biological Survey.

PROFESSOR G. C. COMSTOCK delivered the annual Sigma Xi address at the University of Michigan on May 24, speaking on "The Visible Universe as a Subject of Current Speculation."

PROFESSOR ELIOT BLACKWELDER, of the University of Wisconsin, delivered an illustrated lecture on "The Physical Geography of China and its Influence upon the People," on May 3 under the auspices of the College of Science Student's Union of the University of Illinois. The union was organized this year with representatives from the various scientific societies, and it has been so successful that the engineering societies are planning a similar union. Professor H. C. Taylor, head of the department of agricultural economics at the University of Wisconsin, gave three lectures at the University of Illinois on May 16 and 17 on the following topics: "The Economic Conditions which Determine Types of Dairy Farming," "The Economic Aspects of the Farm Problem," and "The Value of Cost Accounting on the Farm." Dr. A. L. Winton, of the Chicago Laboratory of the U. S. Bureau of Chemistry, lectured last week at the university on "Microscopic Food and Agricultural Analysis," under the auspices of Phi Lambda Upsilon, the honorary chemical fraternity.

THE one hundred and thirtieth Harveian festival will be held in the hall of the Royal College of Physicians, London, on May 31, when the president, Dr. Charles Watson MacGillivray, will give the Harveian Oration on "Some Memories of Old Harveians, with Notes on their Orations."

UNDER the auspices of the Geographical Society of Philadelphia, a botanic and geographic expedition is to be made this summer to southern Florida by Professor John W. Harshberger, of the University of Pennsylvania. Professor Harshberger has made two previous trips to Florida and this expedition is to complete his studies in the Everglades region of the extreme southern part of the

peninsula. The itinerary will be approximately as follows: Making Fort Meyers on the west coast headquarters, Professor Harshberger will first investigate the region in that vicinity; visits will be made to several of the islands along the gulf coast; the Caloosahatche will be ascended by power boat to Lake Okeechobee and the flora of that inland lake will be studied. Then the attempt will be made (if the drainage canal has been sufficiently constructed) to cross the Everglades to Fort Lauderdale on the east coast. As no botanical geographer has ever crossed the Everglades, unusual opportunities will be presented to study a region of great scientific interest. Photographs will be taken of the vegetation, the region will be mapped botanically, and a collection of the more interesting plants will be made. An abstract of the results of this expedition will be published in the October number of the *Bulletin* of the Geographical Society of Philadelphia.

THROUGH the liberality of a friend, the Smithsonian Institution will be enabled to participate in a zoological expedition to the Altai Mountain region of the Siberian-Mongolian border, central Asia, an exceedingly interesting territory, from which the National Museum at present has no collections. Mr. Ned Hollister, assistant curator, division of mammals, U. S. National Museum, will represent the institution and make a general collection of the birds and mammals. He will have as a field assistant Mr. Conrad Kain, of Vienna, Austria, an Alpine guide. The party leaves New York on May 22 for London, whence the field will be reached by way of St. Petersburg and the Siberian Railway. The scene of the survey and exploration, the Altai Mountain region, is a particularly wild country. These mountains are inhabited by the largest of the wild sheep, which, with the ibex, will form the principal big game animals sought by the party, but a complete and general collection of smaller mammals and birds will also be made. At present it is the expectation of the party to remain in the field for four months, returning to the United States about the first of October.

UNIVERSITY AND EDUCATIONAL NEWS

MR. CLARENCE H. MACKAY and his mother, Mrs. John W. Mackay, have given \$150,000 to the University of Nevada, making their total gifts \$400,000.

ALLEGHENY COLLEGE has completed the raising of \$400,000 thereby securing the \$100,000 conditional gift of the General Education Board. This makes the total productive endowment of the college \$1,025,000. At the same time \$20,000 has been given for a new athletic field, \$20,000 to pay a deficit in running expenses and \$60,000 as an endowment fund which is not immediately productive. President Crawford stated in his announcement on the completion of the fund, that the immediate results would be the addition of two new assistant professors and several new instructors to the faculty and the giving of an additional income to the library.

THE corner-stone of the new \$125,000 School of Commerce building of the University of Illinois, was laid on Tuesday, May 21. A special university convocation was held in the auditorium at 4 p.m. Addresses were given by Governor Charles S. Deneen, of Illinois; President E. J. James, of the University; Dean David Kinley, director of the Course of Commerce; President W. L. Abbott, of the board of trustees, and others. In addition to the usual subjects taught, such as insurance, public finance, business organization and economics, etc., the school will give courses in shop and factory organization and management.

DR. C. A. DUNIWAY, whose term of office as president in the University of Montana, was, as readers of SCIENCE will remember, terminated by the regents, has been elected president of the University of Wyoming. The University of Wyoming has about twice the income of the University of Montana.

DR. ALEXANDER MEIKLEJOHN, professor of philosophy and dean of the faculty of Brown University, has been elected president of Amherst College.

PROFESSOR B. M. DUGGAR, of Cornell University, has been elected to fill the professor-

ship of plant physiology and applied botany in Washington University, vacated by Dr. George T. Moore in accepting the directorship of the Missouri Botanical Garden.

MR. REYNOLD K. YOUNG (A.B., Toronto, '09), for the past three years fellow in Lick Observatory, has been appointed instructor in astronomy and physics in the University of Kansas. Mr. Young takes his doctor's degree from the University of California in June.

MR. ANSEL F. HEMENWAY, of the University of Chicago, has been appointed professor of biology and geology in Transylvania University, Lexington, Ky., to succeed Professor Charles A. Shull who has recently resigned.

PROFESSOR J. K. H. INGLIS, of University College, Reading, has been elected professor of chemistry at Dunedin University College, New Zealand.

DR. RICHARD GANS, docent for physics at Strasburg, has been elected professor of experimental physics at the University of La Plata.

MR. JAMES HENDRICK, lecturer in chemistry at Aberdeen Agricultural College, has been appointed professor of agriculture in the university.

DR. HERMANN BRAUS has been promoted to be full professor and director of the anatomical laboratory at Heidelberg.

DISCUSSION AND CORRESPONDENCE

THE WHITE-TAILED DEER OF MICHIGAN

Two white-tailed deer, *Odocoileus virginianus* Bodd. and *O. v. borealis* Miller, are said to occur in Michigan. The northern form (variety *borealis*) is still abundant in the northern peninsula, and numerous specimens from that region are in the University of Michigan Museum of Natural History. But unfortunately in the southern peninsula the deer have become nearly exterminated, and as apparently but very few specimens or sufficiently careful descriptions of specimens

have been preserved, and this is the part of the state in which one would look for the typical form, the problem of determining the species that formerly inhabited this region is not an easy one to solve.

The northern limit of the range of the typical form has only been vaguely given by the different authorities. Thus Hahn¹ says "from the region of the Great Lakes," Rhoads² states that it occurs "from southern New York and Michigan," and Seton³ gives it approximately the two southern tiers of Michigan counties in his map of the range of the species. Apparently none of these statements are based upon definite information, as we have been unable to find any specimens or information that would lead us to believe that the typical form ever occurred in Michigan even in the southernmost counties.

There are two skulls from Wexford county in the museum that are evidently to be referred to variety *borealis*, the lower row of cheek teeth measuring 83 mm.⁴ in one and 79 mm. in the other, which has not yet acquired the rear lobe of the third molar. This confirms the opinion held by most writers that the northern form is found in the northern part of the lower peninsula. There are also in the collection, however, a skull from Livingston County (No. 5240) and sub-fossil jaws from Washtenaw County (No. 42,532) and Branch County (No. 42,531) in which the lower row of cheek teeth measures 83 mm., 82 mm. and 90 mm., respectively. These specimens with the statements of former residents⁵ of Washtenaw and Wayne counties that the deer of these counties had a gray coat in winter seems to constitute pretty clear evidence that the variety *borealis* formerly ranged

UNIVERSITY OF MICHIGAN
MUSEUM OF NATURAL HISTORY

THE FLORA BRASILIENSIS

TO THE EDITOR OF SCIENCE: Referring to the note regarding the set of the "Flora Brasiliensis" recently acquired by the University of Illinois and the statement that it is the fourth obtained by American libraries, the others being at Harvard, Columbia and the Shaw Botanical Gardens,¹ it may be worth while to state that there is a complete set in the library of the Academy of Natural Sciences of Philadelphia, the volumes issued prior to the abdication of Dom Pedro II. having been received as a gift from him in evidence of his appreciation of the attentions shown him by the academy in 1876, during his attendance on the Centennial Exposition.

A detailed account of the emperor's visit will be found in my "History of the Academy."

EDW. J. NOLAN,
Secretary and Librarian

TO THE EDITOR OF SCIENCE: In your department of "Scientific Notes and News" of April 26, 1912, there is a statement that the set of "Flora Brasiliensis," which has just been added to the natural history library of the University of Illinois makes the fourth set obtained by American libraries, "others being at Harvard, Columbia and the Shaw Botanical Gardens." Will you kindly mention the fact in SCIENCE that the library of the Ohio State University has a complete set of "Flora Brasiliensis"? In the very early days of the university the first parts of the "Flora" were presented to the university by Mr. William S. Sullivan, of Columbus, with the understanding that the university would keep up the subscriptions. This was done and the parts as issued were received regularly by the university library. On the completion of the

¹ SCIENCE, XXXV., No. 904.

work it was bound in volumes, making a very handsome as well as valuable set.

OLIVE JONES,
Librarian

AN EXPERIMENT ON A FASTING MAN

THERE was completed at this laboratory on May 15 a successful 31-day experiment during complete inanition, the subject drinking 900 c.c. of distilled water per day. Elaborate measurements of the gross metabolism as indicated by the carbon dioxide production, oxygen consumption, water vaporized and heat elimination were made on each day. Continuous records of rectal temperature, pulse rate, respiration rate, ventilation of the lungs, blood pressure, microscopic blood examination, careful clinical examinations, anthropometric measurements and psychological tests were a part of each day's routine. Photographs of the subject at stated times and X-ray plates at the conclusion of the fast were secured. Complete urine analyses were also made throughout the 31 days. The mass of data will require several months for complete and verified computation.

Newspapers and magazines, actuated only by the sensational element, have used every means to secure advance statements, and in some instances have issued "faked" statements, regarding this experiment. The results will be presented only in the publications of the Carnegie Institution of Washington or in the regularly accredited scientific journals, and any prior statements purporting to be made by me or signed by the subject, A. Levanzin, are to be disregarded.

SCIENTIFIC BOOKS

The Pines of Australia. By RICHARD BAKER and HENRY G. SMITH. Technical Education Series, No. 16. Sydney, 1910.

The present publication of the department of public instruction of the state of New South Wales is a memoir of over four hun-

dred and fifty pages, copiously illustrated by means of photographs and photomicrographs and accompanied by two maps showing the distribution of the "Pines." Many of the illustrations represent more or less accurately the appearance of stained microscopic sections reproduced by the three-color process. It seems questionable even in a semi-popular work like the present to use the term "Pines" to represent the Conifers as a whole. Such an appellation is almost sure to lead to misconceptions on the part of the reader, particularly in the southern hemisphere, where true pines are conspicuous by their absence. The authors are at some disadvantage on account of the multifariousness of the task they have set themselves, for they aim to include in their account of these trees, their systematic relations, the history of the names given them, their morphology and anatomy, their useful products, including the chemistry of some of these and finally their geographical distribution. This appears to be too large a field to be covered successfully or fully, even by the collaboration of a chemist and a botanist.

Under the head of morphology and anatomy are recorded observations as to the significance of the "spur" of the cone scale of the genus *Callitris* and the probable function of the central columella in the cone of the same genus. It is noted that the chemical products, particularly the resinous ones of species which resemble one another morphologically are very strikingly similar. Attention is called to the presence of manganese compounds in the parenchymatous cells of the wood of *Callitris* and other genera. The manganese content in some cases is very considerable. The value and nature of the tannins and sandarac resins of *Callitris* are discussed and similar accounts are given of the gums, resins and oils of the other coniferous genera of the Australian flora.

The volume concludes with appendices on the systematic value of the chemical products of plants, on the distribution of Australian conifers, and on the collaborators, who have assisted in various ways in the preparation of the work. There are likewise several good

maps which further illustrate the subject of distribution. The present work will be of considerable value to those interested in the economic products of Australia and to botanical travelers in that region.

The Eusporangiatæ, the Comparative Morphology of the Ophioglossaceæ and Marattiaceæ. By DOUGLAS HOUGHTON CAMPBELL, Carnegie Institution of Washington, August, 1911.

This superb memoir deals with the representatives of two important orders of ferns, the Ophioglossales and the Marattiales, which on account of their remote and often tropical distribution are imperfectly known. The illustrations are admirable scientifically and are often extremely artistic. Thirteen full quarto page heliotypes representing the habit of the rarer species are of great beauty. While the author deals adequately with those features of the morphology of the Eusporangiates, which have been accessible to other writers, he naturally devotes special attention to the question of the structure and development of the gametophytes and the young sporophyte, since it is precisely in regard to these matters that our present knowledge is least perfect. With entirely admirable zeal, Professor Campbell has made it his business to visit those remote parts of our earth which are at the same time most interesting botanically and least salubrious and accessible.

An account as complete as is permitted by the abundant material rendered available by the author's extensive travels is given of the gametophytes of the three Ophioglossaceous genera, *Ophioglossum*, *Botrychium* and *Helminthostachys*. This is supplemented by descriptions of the development of the embryo and the later stages of the young sporophyte. It is clear that Professor Campbell inclines to the opinion that the leaf is the primitive fern organ and for him the genus *Ophioglossum* is likewise the primitive genus of the Ophioglossaceous family. There appears to be here much room for difference of opinion, since the whole tendency of investigation in recent years, covering both the living and fossil rep-

resentatives of the lower vascular plants, whether cryptogamic or seed-bearing, has been to show that the course of evolution has been from the more complex to the simple and not as has been generally assumed in the past *vice versa*. Unfortunately in the case of the Ophioglossaceæ no fossil evidence is available to check up the results obtained from the study of the morphology of the living forms. In accordance with his point of view, the author apparently regards the stem of the Ophioglossaceæ as a complex of fused leaf bases, a conception supported in his opinion by the method of development of the vascular strands. He apparently regards the fertile segment of the leaf too, the so-called sporangiophore, as an organ *sui generis*, although Professor Bower, the most vigorous defender of this point of view, has recently practically abandoned it. The possibility of the sporangiophore representing specialized pinnæ of the leaf, which has recently been convincingly urged by Professor Chrysler, is not entertained.

The account of the Marattiales given by the author is particularly full and original and does full justice to the admirable opportunities of travel and collection which he has enjoyed. Of particular interest is the account of the gametophyte, sexual organs and embryonic development of the monotypic genus *Kaulfussia*, by reason of its marked resemblance to the fossil forms referred to the Marattiales. A feature of this second division of the memoir is the attention given to the development of the fibrovascular system. The author takes the position that the origin of the first tracheids as separate groups, which only later become merged in the general fibrovascular system of the stem, indicates the origin of the axis from originally separate parts. This doctrine carried to its logical conclusion would apparently lead to somewhat striking absurdities.

The third division of the memoir is devoted to the discussion of the origin and relationship of the two fern families described in the earlier pages. The author assumes the correctness of the antithetic hypothesis of the origin of the alternation of generations, char-

acteristic of all vascular plants. In this connection he definitely homologizes the moss sporogonium with the sporophyte of ferns. Obviously he entertains the view that *Ophioglossum* among the Ophioglossaceæ is probably the most primitive representative of the fern stock. There appears to be little support for the correctness of this view and it entirely lacks the confirmation of fossil evidence, which in this case is unfortunately lacking. Logically in accordance with the general attitude just indicated, the author derives the Marattiaceæ from ancestors allied to the Ophioglossaceæ. He acknowledges in this connection the serious difficulty of bridging over the morphological gap, between the dorsisporangiate foliar organs of the Marattiales and the so-called sporangiophore of the Ophioglossales. This difficulty appears to the reviewer to be very great indeed, especially in view of the known antiquity of the Marattiales and the apparently recent origin of the Ophioglossales. It further appears from a consideration of the reproductive parts and anatomy of the sporophytes as well as of the gametophytes, that it is much easier to derive the Ophioglossaceæ from typical ferns such as the Marattiaceæ, than it is to entertain the possibility of a reverse course of evolution.

The Morphology of Gymnosperms. By COULTER and CHAMBERLAIN. University of Chicago Press. 1911. Postpaid, \$4.22.

The present volume is undoubtedly the most important general work on the gymnosperms which has ever appeared and is highly creditable to American science. It consists of four hundred and fifty pages and of an equal number of, for the most part, original and remarkably good illustrations. The book is characterized throughout by a sane, broad and withal interesting treatment. The views expressed as to affinities and evolutionary sequence are for the most part clearly, logically and convincingly stated.

The volume is modeled on evolutionary lines, grounded on the solid foundation of the testimony afforded by the rocks, and in this respect presents an agreeable contrast to most

botanical works on plant evolution, which are too often written by persons who have no knowledge or appreciation of the past history of plants. In accordance with this feature, it begins with the oldest known seed-plants, the Cycadofilicales as the authors more logically term the Cycadofilices of Potonie and the Pteridospermeæ of Oliver and Scott. The enormous progress made in our knowledge of the evolution of the gymnosperms is nowhere better illustrated than in this chapter, which may be instructively compared with the meager amount of information supplied on the same subject in the first edition published ten years ago. Here we find an extremely good account of this fascinating primitive group of gymnosperms, long mistaken for ferns, whose true affinities were guessed at by the German paleobotanist Potonie and proved by Oliver, Scott, Grand'Eury and David White.

Logically following the Cycadofilicales, with the interposition of the Cordaitales, which need not be specially referred to in this connection, come the true Cycads and their allies the Bennettiales. The Chicago laboratories have added much to our knowledge of the Cycadales, and the chapter on this group of gymnosperms, now confined to the warmer regions near the equator, is one of the strongest in the book. The Bennettiales, the Cycads of the earlier Mesozoic, owe their elucidation to a large extent to the striking investigations of Dr. Wieland, of Yale University. We find them treated with the fulness which their importance demands.

Next to the Cycad-like gymnosperms come the relatives of the maidenhair tree, Ginkgo, sole survivor, through the pious care of the Japanese priests, of a stock which in the Mesozoic flourished abundantly throughout the northern hemisphere.

The Conifers, the most abundant and important gymnosperms of our existing flora and of great evolutionary importance on account of their extension into the remote past, appropriately occupy about one third of the volume. The gametophytes of this group, which have been particularly the subject of

investigation at Chicago, naturally come in for full consideration, but the past history and the important anatomical features of the Coniferales have not been overlooked. The great influence of modern anatomical and paleobotanical work is nowhere more clearly shown than in the systematic grouping of the Conifers along evolutionary lines. One illustration will serve to make this clear. In the first edition of the present work, which appeared ten years ago, the pine was considered to represent the highest member of the Conifers on account of the complexity of its vegetative and reproductive structures. In the present edition, it is put near the bottom, if not at the very bottom, of the coniferous series, since recent investigations, paleobotanical and anatomical, have demonstrated its great antiquity and at the same time the truth of the general proposition that the Conifers are a reduction series in which the simplest members are most modern and not an ascending one, in which the most complex representatives are the highest.

The Gnetales, which on account of their supposed affinities with the angiosperms are of great botanical interest, are adequately treated. The riddle of their existence is discussed in an entirely unpartisan manner. Following this chapter is one on evolutionary tendencies among the Gymnosperms. This part of the volume is naturally the one about which there is the greatest room for difference of opinion, and it is precisely here that the authors deserve the highest praise. At the present moment the older morphology is in process of resolution under the influence of experimental and paleobotanical activities. For that reason a clear expression of evolutionary sequence, even of groups concerning the past history of which we are well informed, as is relatively true of the Gymnosperms, is extremely difficult. Notwithstanding, in the present volume, we find a remarkably clear position taken, although not entirely unaffected by the back eddies resulting from the partial persistence of the older standpoints.

E. C. JEFFREY

HARVARD UNIVERSITY

Pharmaceutical Bacteria, with Special Reference to Disinfection and Sterilization. By ALBERT SCHNEIDER, M.D., Ph.D. Published by P. Blakiston's Son & Co., Philadelphia, Pa. Price \$2.00.

The rapid development of bacteriology in various directions has led to the publication of books in considerable number, showing the application of bacteriology to different phases of modern life. Medical bacteriology, agricultural bacteriology, industrial bacteriology and various other aspects of this new science have been fairly well exploited. The present book is in a new line, and is designed simply to cover the relations of bacteriology to pharmacy—being intended primarily for students in college of pharmacy and incidentally to pharmacists in general. The subjects that are treated in the work are only those which have some practical relation to this business. After a general introduction there is a brief but comprehensive historical survey of the development of bacteriology, divided into periods and bringing the subject up to date. This is followed by a general description and classification of bacteria, with the method of bacteriological technique, and then brief considerations of the relation of the bacteria to a few industries, like agriculture in general, dairying, the extermination of pests, canning, cider-making, etc. A somewhat extended discussion of the problems of immunity and the activities of bacterial products, together with a discussion of the manufacture of sera and vaccines, is naturally given in a book of this nature, the subject being treated from both a theoretical and a practical standpoint. Disinfection and the use of various disinfectants are discussed quite extensively, the subject being considered from the standpoint of the disinfection of water, of food, of dwelling houses, of surgeons' supplies, of various chemicals that are liable to be handled in the pharmacy; in short, all relations of disinfection which have a bearing upon the problems of the pharmacy, are carefully considered. A chapter upon communicable diseases and their prevention treats very briefly of the

better-known bacterial diseases and the most modern preventive methods; and lastly a suggestion is given for the equipment of a moderate sized laboratory for the pharmacy.

The book in general is well written, well illustrated, and will be useful for the people for whom it is particularly designed. As a book on bacteriology for the general student, however, it is too narrow in its scope to be of any great value or interest. As its title indicates, it is a pharmaceutical bacteriology, and its place is simply in schools of pharmacy and in the hands of pharmacists.

H. W. C.

The American Year Book. 1911. Edited by FRANCIS G. WICKWARE, B.A., B.Sc. New York, D. Appleton & Co.

The American Year Book in its second issue presents a carefully collected and compiled record of events and progress, largely with reference to the year 1911. There are here gathered facts of use to writers of many kinds, covering many fields, scientific, somewhat aside from science, like history and politics, and others into which science is to-day entering, like economics and the social questions. Industries and occupations are considered under a number of grouped heads, while the sciences themselves and engineering are ranged in some seven groups. There follow the humanities, an epitome of chronology and necrology and some references to the volume of 1910, which, being the first, reviewed and outlined a number of subjects.

There are two criteria for determining the quality of a volume like this; one its actual fitness for the purpose for which it is intended and the other the list of contributors. The first-named can be reliable only after a season of trial, and the excellences or demerits may not be apparent on cursory inspection. Taking the list of names of the authors of the various essays, they should stand for a superlative product. It was Dr. Walter Wyman who prepared the article on Public Health and Hygiene, the revision after his death being done by Dr. Schereschewsky.

There are here reviewed the world movements of epidemic diseases and the incidence and movements of the same within the United States. The writer does not fail to note in an authoritative way the measures of defense against the threatened invasion of cholera during the year, the unusual prevalence of smallpox, the improvement in the mortality rate of tuberculosis, the story of anti-typhoid vaccination, not forgetting a word of warning against measles and other diseases so common that no one fears them, yet which take large toll. In this connection it is interesting to note that the infant mortality can be given for eight states, only, Michigan being the sole one away from the Atlantic coast in which the registration is sufficiently good.

International statistics for world and country are presented from authoritative sources, government reports, local bulletins and the like. Some of the items are populations, national revenues and expenditures, products like cotton and wool, grains, coal and iron. These will be invaluable to persons needing such data. The international mortality rates given in the first grouping of figures is from an English source, the Registrar General's Annual Summary. It is curious that while taking places of as low rank in point of population as Stockholm and Bucharest, Prague, Trieste and Melbourne, the latter somewhere not far above 100,000, there are omitted such places as Tokio, Buenos Ayres, Liverpool, Warsaw, Manchester, Naples, etc., so that only about one third of the cities above half a million are represented. There must be better sources than that selected if full information is desired.

The third group, the Problems of Population, takes up many matters, one interesting one being the change in the shape of the head noticeable among the children of immigrants. For history there is a résumé of the political parties and their changes, some words on reciprocity and the tariff; conservation is considered and trusts and court decisions affecting corporations, etc. There is a good deal of space devoted to foreign history. Govern-

ment, national, state and municipal conditions are discussed at length; there is a consideration of economic conditions and labor questions, the items thus far occupying about half the bulky volume.

In matters of science the treatment is of rather restricted divisions, generally by those in the employ of the government or with colleges. In agriculture, Allen, Hooker, Evans, Knight and Glasson, all of them related to some bureau, discuss, respectively, the census of 1911, diseases of live stock, diseases of plants, legislation and horticulture, while Morse, of the Bussey Institute, considers live stock, and Felt, of Albany, the seventeen-year locust. Ethel Marion Smith, of the Bureau of Fisheries, takes up briefly the story of the fisheries. In similar manner Locke and Wilson, of the Massachusetts Institute of Technology, present reviews of mining and ore-dressing and coal, coke and petroleum, while Hofman, of the same school, discusses lead. Here no government expert is heard, but Fulton, president of the South Dakota school, Macgregor, of Columbia, and two engineers and an editor, Stoughton, Fulton and Ingalls, contribute other special articles. Mathematics in general is from the pen of Wilson, of the Massachusetts Tech, while Todd, of Amherst, writes quite at length and in an interesting manner of the astronomical world, outlining the important movements of the science. Geological topics are divided between Woodworth and Palache, of Harvard, Reid, of Johns Hopkins, who discusses vulcanology and De Wolf and Ransome. Meteorology of course is considered by Ward, of Harvard, terrestrial magnetism by Faris, in government employ, and in geography, Davis, of Harvard, is the only college man, Gannett and Littlehales, of Washington, and Adams, editor of the publications of the American Geographical Society, caring for the other sections. Chemistry enlists a full company of experts, Cornell and Columbia tying the government number, two, with one each from Technology and Wisconsin, while the story of physics is presented by Saunders, of Syracuse. In the same way are taken up zoology, botany, paleontology, eth-

nology and archeology, the last three together by the presentation of abstracts of the books, publications and society achievements of the year. These notings will serve to show the method in which the subjects are attacked and the kind of men who have contributed the different essays. Psychology and philosophy, medicine and surgery and engineering follow, while religion, the arts and literature round out the whole.

The book is of convenient size, 8vo, well printed on light-weight paper, so that it is—despite its bulk of 900 pages—not inconvenient to hold in the hand, and it is quite well indexed by larger topics, which will probably serve the purpose since the articles are in general not long and are arranged with well-displayed headings.

JOHN RITCHIE, JR.

NOTES ON METEOROLOGY AND CLIMATOLOGY

A NEW AEROLOGICAL LABORATORY

THE close relationship between meteorology, the science, and aviation, the art, is becoming more generally recognized as time progresses. At present there is being erected at Rostock, a small city in northern Germany, on an arm of the Baltic Sea, an institution which is to be an aerological observatory as well as an aeronautical laboratory. The aerological researches will be based upon data obtained from aloft by means of kites and balloons, while the aeronautical experiments will consist mainly of the adaptation of aircraft to the conditions thus determined. Professor Otto Kriimmel will direct the aerological investigations, while Captain Alfred Hildebrandt will have charge of the aeronautical work, which will include a manufacturing plant. Because of the favorable location especial attention will be paid to hydro-aeroplanes. As is customary in Germany, municipal aid will be given the new institution.

THE NEW YORK METEOROLOGICAL OBSERVATORY

THE New York Meteorological Observatory, located in Central Park, New York City, has

recently been placed under the supervision of the U. S. Weather Bureau. This institution, the first in the country to be equipped with self-recording meteorological instruments, was founded by Daniel Draper, Ph.D., in 1868. The expense of conducting the work of the observatory was provided for by municipal appropriations, while the founder remained the active director until his retirement a year ago. The meteorological record, exceeding in length that of the Signal Service and Weather Bureau, has been constantly referred to by a variety of interests in the development of the American metropolis. Under the new arrangement the Weather Bureau has two observatories in New York City. At the Central Park station observations are taken for the city by the federal officials just as was done when it was entirely under city supervision.

ICE STORMS

WHEN rain falls while the temperature of the lower air is below freezing the drops solidify immediately after striking solid objects, and we have an ice storm—a frequent occurrence in the northeastern part of the United States. The precipitation continues in the form of rain when the temperature of the air near the ground is sometimes as low as 9° F., showing that there must be an inversion stratum but a short distance aloft, otherwise the condensation would result in the formation of solid particles rather than liquid drops. In New England, where these storms are particularly frequent, it is not uncommon for the ice to accumulate to a depth of an inch on all exposed objects, and on one occasion, February 14–16, 1909, ice was thus formed to a thickness of three inches in the suburbs of Boston, and did not disappear until four days after the storm had ended. The supposition that there is a relatively warm stratum aloft during an ice storm was verified by means of a kite flight at Blue Hill Observatory on March 7 last. In that flight the auxiliary kites added to lift the line became so heavily coated with ice that they pulled the leading kite down instead of aiding in its

ascent, thereby rendering the maximum height reached during the flight considerably lower than usual. It was found that the air was practically isothermal from the summit of Blue Hill (200 meters above sea-level) to 625 meters above sea-level, the temperature being about 30.8° F. Beyond the latter level, however, the temperature increased steadily with height, and was 36.8° F. at 874 meters, the maximum height reached by the meteorograph. Raindrops falling from this relatively warm stratum were undercooled by their passage through the colder air below, and immediately changed to ice upon striking solid objects.

EXTREME COLD IN THE UNITED STATES

IN persistence and severity the cold experienced in the central and eastern parts of the United States during January and February is noteworthy, as is seen from the following: At Grand Forks, N. D., the temperature fell to zero or below every day of January except the last, the lowest temperatures for all the days of the month averaging —20.0° F. At Washta, Iowa, —47° was officially recorded January 12. At Chicago, Ill., where the average daily deficiency was 11.9° F. the month was the coldest since the establishment of the Signal Service station there in 1871, and in unofficial records prior to 1871, extending back to 1830, the coldest January was 1.4° warmer than that of 1912. The mercury fell to zero or lower on 13 days, 10 of these being consecutive, and was continuously below zero for 79 hours during the 3d–7th, the longest period on record there. At Washington, D. C., usually a place of mild winter weather, —14° was recorded January 14, this reading being within 1° of the lowest temperature officially recorded there in 42 years, which is the length of the record. Some results of the extreme cold were unprecedented. For the first time since white man has lived in its vicinity Lake Superior was frozen over from shore to shore, the ice being of sufficient thickness to allow moose to cross from Canada to the American shore, according to press dispatches. For the first time in 28 years ice completely spanned Lake Michigan in places

on February 10. Lake Erie was also frozen completely across in some places. Since 1885 Cayuga Lake, in New York State, has not been frozen from end to end until last winter. Many important harbors along the Atlantic coast were kept open only by the ceaseless work of ice-breaking vessels, and for more than a week Long Island Sound was ice-covered, except for the narrow lane kept open by the frequent passage of steamers. Fire losses in the United States for the six weeks ending February 17 were the heaviest for a period of that length in the history of American underwriting, barring periods in which notable conflagrations occurred. The losses for January, 1912, were 67 per cent. greater than those of the same month a year ago, and 134 per cent. greater than those of two years ago. These facts are explained by underwriters as being largely due to frozen water-mains and hydrants, and to snow-blockaded streets, which handicapped the firemen. Doubtless the "oldest inhabitant" can recall many winters which were accompanied by considerably heavier snowfall, severer and more frequent storms and higher and more destructive winds than those just experienced, but few there are probably who can remember a longer period of frigid temperatures, with results similar to those cited.

WINTER WEATHER IN FLORIDA

FLORIDA, widely advertised as having "perpetual summer," or as one railroad puts it, "where every day is a June day," has been generally regarded as having a fountain of perpetual something or other ever since the days of Ponce de Leon. Its real climate, however, did not receive careful attention until large numbers of settlers were attracted by the recent land-boom. In A. J. Henry's "Climatology of the United States" it is stated that in 1886 and 1894 frost destroyed practically all citrus fruits in the state, and in 1895 and 1899 trees in the northern counties were killed in that manner. During the past century there have been at least seven severe freezes in the state, during two of which, 1835 and 1899, practically a zero temperature prevailed over the interior of the

northern and western counties. Snow has fallen over the greater portion of the state, and on February 7, 1835, when a temperature of 7° above zero was recorded in Jacksonville, the St. John's River was frozen. A temperature of -2° F. has been recorded within the state. In all but eight of the last seventy years freezing temperatures have occurred in Jacksonville. January last, an extremely cold month over much of the United States, was also severe in Florida. The isotherm of freezing reached as far south as the middle of the peninsula on the 16th. At Miami, latitude 26° N., the most southerly city on the mainland of the United States, frost was recorded on February 11. As a winter resort contrast Florida with certain parts of California. According to official reports, 42° F. was the lowest temperature recorded during January at both San Francisco and Los Angeles.

A STORM DETECTOR

REFERENCE has already been made in these notes¹ to the use of a wireless telegraph receiver to detect the approach of storms through the waves set up by electrical discharges. The idea was taken up by M. Flageolet, who has just invented an instrument of such acute sensitiveness that it records a storm at a distance of 300 miles. As it usually takes a storm about a day to travel this distance, the practical importance of the new invention will be considerable. The instrument was recently demonstrated before the Academy of Sciences in Paris by M. Violle.

THE DISTRIBUTION OF RAIN IN CYCLONES

THE distribution of rain in cyclonic storms has long been a problem of interest to meteorologists. As yet, however, all do not agree as to the region of heaviest precipitation with reference to the storm center. From early investigations it appeared that the rainfall was heaviest near the center of the depression, and became less and less toward the sides. Observations made at Blue Hill Observatory showed that clouds were densest and most fre-

¹ SCIENCE, Vol. XXXI, No. 807, June 17, 1910, p. 952.

quent in the southeast quadrant of a depression. Professor Waldo ("Elementary Meteorology," p. 221) says:

In the eastern and northern parts of the United States the area of maximum rainfall lies southeast of the center of the cyclone, and usually at a distance of about 300 miles from it; but the distance varies greatly in individual instances.

In New England, however, the rainfall seems to be heaviest in the northeast quadrant of a cyclone, the precipitation accompanying a "northeaster," in which the center of the depression remains south of the observer during its eastward movement, is usually heavier than that of a storm whose center passes down the St. Lawrence Valley. Dr. Shaw ("Forecasting Weather," p. 206) seems to be of the opinion that the precipitation is most abundant, or at least is most frequent, in the "left front of the depression." In the latest discussion of the problem, Mr. F. J. Wardale (*Symonds's Meteorological Magazine*, February, 1912, p. 8) concludes that when a depression crosses England the bulk of the rain falls in subsidiary eddies on its northern side, the region of heaviest precipitation as the storm advances being "a broken band parallel to or gradually diverging from the central track on its left side." He believes that these eddies, too shallow to be evidenced on the meteorological charts, have a counter-clockwise orbital movement around their primary, at the same time sharing its forward movement. These eddies, in which the heavier downpours occur, pass quickly over and hence give slight precipitation to a place south of the storm track, for there they are accelerated by the general forward movement. For a place to the north of the center, the orbital velocity of the secondary is subtracted from the general forward movement, consequently the eddy passes slowly and in some cases might remain stationary, resulting in prolonged and therefore heavy rain. These eddies, he believes, are formed at intervals during the progress of the cyclone, thus accounting for the patchiness of the band of high rainfall. Mr. Wardale's suggestions are well worth the serious consideration of forecasters, since unno-

ticed secondaries and trough-like isobars have often resulted in heavy precipitation when fair weather was expected. His conclusions agree closely with those previously reached by Mr. W. G. Reed in a study of the cyclonic distribution of rainfall in the United States (*Monthly Weather Review*, October, 1911, p. 1609).

NEW BOOKS

AMONG the books which have recently appeared are: (1) "Meteorology," by W. I. Millham. New York, The Macmillan Co. 8vo. 549 pp. \$4.50 net. (2) "Weather Signs and How to Read Them, for Use at Sea," by W. Allingham. Glasgow, J. Brown & Son. 117 pp. 2s. net. (3) "The Sun," by C. G. Abbot. New York, D. Appleton & Co. 448 pp. (4) "Über die Helligkeit des Himmels in der Nahe der Sonne," by H. Diercks. Kiel, Lüdtke & Martens. 48 pp. (5) "Über die Gesetze der Wärmestrahlung," by W. Wien. Leipzig, J. A. Barth. 21 pp. 1 Mark. Among the books soon to appear are: (1) "The Meteorology of the Globe," by W. N. Shaw. (2) "Clouds," by C. T. R. Wilson. (3) "Structure of the Atmosphere," by C. J. P. Cave. (4) "Weather-science," by G. F. K. Lempfert. (5) "Radiation," by P. Phillips. Professor R. DeC. Ward has begun the preparation of a "Climatology of the United States."

ANDREW H. PALMER

BLUE HILL OBSERVATORY,

SPECIAL ARTICLES

THE ORIGIN OF ERYTHROCYTES BY A PROCESS OF
CONSTRICTION OR BUDDING

It is gradually becoming apparent that in the solution of some of the more intricate morphological problems, involving phenomena of development and histogenesis, recourse will be necessary, in part at least, to data other than those obtained from fixed and stained preparations alone. Sabin, '05, in a discussion of evidence from fixed histological material bearing on certain questions regarding lymph-

ocytes and lymph glands has well expressed this conviction in the conclusion that "we must await some new method of attacking the problem." The recent development in the technique of tissue culture, with the striking results obtained by Harrison, Burrows, Lewis, Loeb and others, leads one to expect that similar methods may yield important data concerning the complicated problem of the life history and genetic relationship of the various types of blood cells. With this hope a study of the behavior of blood corpuscles in plasma cultures was begun somewhat over a year ago. Some of the results regarding the red blood cells appear of sufficient importance to justify a preliminary statement.

The present observations relate to the origin of the erythrocytes or non-nucleated red blood corpuscles and bear directly upon the long-standing question of the elimination of the nucleus. The description will be confined to certain results reached in a study of the blood of the pig embryo. Stating the method briefly, the erythroblasts of the embryonic blood were taken at various stages of differentiation and observed in hanging-drop cultures, employing the technique devised by Harrison and Burrows, with such modifications as appeared essential for the present purpose. Biased by the prevalent view that the nucleus of the erythroblast subsequently disappears, either by disintegration or by extrusion, it was hoped that it might be possible to observe the process directly in the living cell. It can be readily appreciated then with what surprise it was discovered that erythrocytes may arise in a manner fundamentally different from either of the above alternatives.

During the first half day (circumstances necessitated beginning the cultures in the afternoon) the erythroblasts manifest a variety of cytoplasmic activities, not inadequately described as amoeboid in character. Numerous pseudopodia-like projections of various types are present. The greater number are in the form of tapering points or slender, elongated processes, varying from one to several in a given erythroblast. In a smaller number of cases the cytoplasm extends out in

blunt, rounded, somewhat bud-like projections. These processes manifest constant quivering and oscillating movements. Other erythroblasts, spherical in form, are more or less quiescent. During the second day, of the above types of processes, the blunt bud-like form has become much more predominant. In other respects the cells appear as on the preceding day. These bud-like processes may involve one third or even more than one half of the cytoplasm of the cells. A striking feature is that not only are the buds completely filled with hemoglobin, but in many cases practically the entire hemoglobin content of the erythroblast has become segregated in the bud, leaving a more or less clear and hemoglobin-free cytoplasmic area surrounding the nucleus. If observations are begun upon the cell at this stage, the bud will be found in a state of amoeboid activity manifested in changes in the contour varying from slight modifications to elongated projections. If the cell is at the height of its activity an astonishing thing may now occur: a constriction becomes evident and within a few minutes or even seconds this constriction is completed and the hemoglobin-containing bud is liberated from the cell. Typically this liberated bud corresponds in size and appearance with the adjacent erythrocytes; it may assume a bi-concave disc shape, and in one instance it was possible to continue the observations sufficiently to follow the final transformation of the liberated bud beyond this disc shape to a typical cup-shaped form. In each case control specimens of the blood originally employed for the cultures were fixed in formalin vapor and stained. Budding erythroblasts were also successfully fixed and stained and were found to correspond both in their cytoplasmic and nuclear characteristics with the control specimen. Erythroblasts were maintained in normal condition in several experiments for three or more days. Budding activities were continuous throughout this time, and under favorable conditions ten or more cells in various stages of active budding could be counted in a given field of the microscope.

When these remarkable activities were first observed it seemed incredible that we were witnessing a normal mode of erythrocyte formation. The experiments were consequently repeated many times, subjected to various tests, and the results analyzed in the light of all the criticism that could be brought to bear upon the subject. Temperature, media, evaporation, staining reaction and degenerative changes have been carefully considered. It is a pleasure to state that Professor R. J. Terry and Mr. C. H. Danforth, of the anatomical department, have also carefully followed these erythroblast activities and have kindly subjected the results to valuable criticism. In brief, after careful study the conclusion seems unavoidable that we are here confronted with a *normal mode of formation of mammalian erythrocytes by a process of budding and constriction from the parent erythroblast*. It is interesting that this result is in accord with the discarded theory of Malassez (1882), on the origin of erythrocytes from bone marrow cells by budding, while at the same time the investigations were made and the conclusions drawn entirely independent of any previous knowledge of his work.

In addition to the formation of typical erythrocytes, another type of activity consists in the production of either very small buds or slender, elongated, rod-like processes which may ultimately segment into a varying number of subdivisions about one third or one fourth the size of the average erythrocyte. These correspond very closely in size and form to blood platelets. As for the amount of cytoplasm remaining with the nucleus, after the constriction off of an erythrocyte, it may vary from a small rim about the nucleus to a quantity occasionally even larger than the erythrocyte to which the parent cell has given rise. No conclusive evidence of a migration of the nucleus from the cell has as yet been obtained. However, in the case of the smaller erythroblasts the constriction may take place so close to the nucleus that it may present the appearance of nuclear extrusion, and it is readily conceivable

that in some cases the constriction may be such as to leave behind a practically cytoplasmic-free nucleus and thus account for the free erythrocytic nuclei occasionally found in the blood. That the fundamental process here described is one of cytoplasmic constriction rather than of nuclear extrusion is still further demonstrated by the fact that occasionally a single large erythroblast was observed to give rise to even two buds, both of which became detached from the parent cell.

Granting that we are justified in the above conclusion, various questions naturally present themselves; among others the behavior of the erythroblasts in different media; the factors involved in the formation of hemoglobin and its separation from the erythroblast; the subsequent assumption by the liberated globule of a disc or cup-shaped form; the fate of the nucleated remainder of the erythroblast, and the possible relationship between lymphocytes and erythroblasts. Investigation bearing on these problems is under way. The present preliminary statement will be followed as soon as possible with a full description of technique, detailed data, and figures upon which these conclusions are based.

ON THE APPEARANCE OF ALBINO MUTANTS IN
LITTERS OF THE COMMON NORWAY RAT,
MUS NORVEGICUS

AFTER several failures to breed the Norway rats in cages, we have finally succeeded in raising them in captivity by means of an improvement in the cages and diet, as well as in general treatment.

This successful experiment was begun more than two years ago and we are just getting the litters which belong to the third generation born in captivity. It may be added that in all cases the brothers and sisters of the same litters were mated as I wished to determine the combined effects of close inbreeding and captivity.

The total number of rats belonging to the third generation born in captivity is not yet large. There are, however, six litters altogether, each having a different parentage. Within these six litters I have found four pure albino rats (white coat and pink eyes) among only brown-coated brothers and sisters. The distribution of these albino mutants within the litters is as follows:

- (1) 7 brown and no albinos, born March 15, 1912.
- (2) 6 brown and no albinos, born March —, 1912.
- (3) 4 brown and 3 albinos, born April 17, 1912.
- (4) 4 brown and 1 albino, born April 17, 1912.
- (5) 12 brown and no albinos, born April 30, 1912.
- (6) 5 brown and no albinos, born May 4, 1912.

This litter was found dead; all had pigmented eyes.

Thus the number of albino mutants in proportion to the brown-coated brothers and sisters is not large, though it may increase in subsequent generations. Although I have been anticipating that such albino mutants might occur sometime, nevertheless it was a great surprise to obtain them within so few generations.

So far as I am aware, this is the first instance in which the albino mutants have been obtained from the common Norway rats under laboratory conditions and I thought the event of sufficient interest to justify this note.

S. HATAI

THE WISTAR INSTITUTE

SOCIETIES AND ACADEMIES

THE AMERICAN MATHEMATICAL SOCIETY

THE one hundred and fifty-eighth regular meeting of the Society was held at Columbia University on Saturday, April 27, 1912, with an attendance of fifty-two members. President H. B. Fine occupied the chair. The following new members were elected: Miss S. R. Benedict, Smith College; Mr. C. E. Fisher, Rhode Island Normal School; Dr. T. H. Gronwall, Chicago, Ill.; Mr. Louis A. Hopkins, University of Michigan; Dr. A. J. Kemper, University of Illinois; Mr. V. C. Poor, University of Michigan; Mr. R. B. Stone, Harvard University; Mr. K. P. Williams, Princeton University. Seven applications for membership in the society were received.

It was decided to hold the annual meeting this year at Cleveland, Ohio, in affiliation with the American Association for the Advancement of Science. The winter meeting of the Chicago Section will be merged in this general meeting of the society. Owing to President Fine's absence abroad, his presidential address will not be delivered at this meeting but at the annual meeting of 1913.

The following papers were read at the April meeting:

R. L. Moore: "Concerning Jordan curves in non-metrical analysis situs."

J. K. Lamond: "Improper multiple integrals over iterable fields."

L. A. Howland: "Binary conditions for singular points on a cubic."

B. H. Camp: "Certain integrals containing parameters."

S. Lefschetz: "On the V_s with five nodes of the second species in S_n ."

E. R. Marshall: "A labor-saving device in computation."

G. D. Birkhoff: "The reducibility of maps."

G. D. Birkhoff: "A determinant formula for the number of ways of coloring any map."

Oswald Veblen: "An application of modular equations in analysis situs."

H. B. Phillips and C. L. E. Moore: "A geometric use of matrices."

H. B. Phillips and C. L. E. Moore: "A theory of linear distance and angle."

L. P. Siceloff: "Sylow subgroups of groups whose orders are of certain special forms."

A. D. Pitcher: "Concerning the continuity and convergence of functions of a general variable."

W. R. Longley: "Proof of a theorem due to Picard."

A. R. Schweitzer: "Remark on a functional equation."

A. R. Schweitzer: "Theorems on functional equations."

Dunham Jackson: "On approximation by trigonometric sums and polynomials (second paper)."

N. J. Lennes: "Concerning Van Vleck's non-measurable set."

N. J. Lennes: "Concerning infinite polygons and polyhedrons."

The next meeting of the society will be the summer meeting, which will be held at the University of Pennsylvania, September 10-11.

MATHEMATICS has a large household and there are always rumors of prospective additions despite her age and her supposed austerity. Without aiming to give a complete list of the names of the members of this household we may recall here a few of the most prominent ones. Among those which antedate the beginning of the christian era are surveying, spherical astronomy, general mechanics and mathematical optics. Among the most thriving younger members are celestial mechanics, thermodynamics, mathematical electricity and molecular physics.

Usually a large household serves as one of the strongest incentives to activity, and mathematics has always responded heartily to this incentive. As the most efficient continued service calls for unusual force and ingenuity, mathematics has had to provide for her own development and proper nourishment in addition to providing as liberally as possible for her household. This double object must be kept prominently before our eyes if we would comprehend the present mathematical activities and tendencies.

There is another important incentive to mathematical activity which should be mentioned in this connection. Mathematics has been very hospitable to a large number of other sciences and as a consequence some of these sciences have become such frequent visitors that it is often difficult to distinguish them from the regular members of the household. Among these visitors are

¹ Read before the Illinois Chapter of the Society of the Sigma Xi, April, 1912.

economics, dynamical geology, dynamical meteorology and the statistical parts of various biological sciences. Visitors usually expect the best that can be provided for them, and the efforts to please them frequently lead to a more careful study of available resources than those which are put forth in providing for the regular household.

We have thus far spoken only of what might be called the materialistic incentives for mathematical development. While these have always been very significant, it is doubtful whether they have been the most powerful. Symmetry, harmony and elegance of form have always appealed powerfully to *dame mathematics*; and a keen curiosity, fanned into an intense flame by little bits of apparently incoherent information, has inspired some of the most arduous and prolonged researches. Incentives of this kind have led to the *mathematics of the invisible*, relating to refinements which are essentially foreign to counting and measuring. The first important refinement of this type relates to the concept of the irrational, introduced by the ancient Greeks. As an instance of a comparatively recent development along this line we may mention the work based upon Dedekind's definition of an infinite aggregate as one in which a part is similar or equivalent to the whole.²

Mathematics is commonly divided into two parts called pure and applied, respectively. It should be observed that there are various degrees of purity and it is very difficult to say where mathematics becomes sufficiently impure to be called applied. The engineer or the physicist may reduce his problem to a differential equation, the student of differential equations may reduce his troubles to a question of function

theory or geometry, and the workers in the latter fields find that many of their difficulties reduce themselves to questions in number theory³ or in higher algebra. Just as the student of applied mathematics can not have too thorough a training in the pure mathematics upon which the applications are based so the student of some parts of the so-called pure mathematics can not get too thorough a training in the basic subjects of this field.

As mathematics is such an old science and as there is such a close relation between various fields, it might be supposed that fields of research would lie in remote and almost inaccessible parts of this subject. It must be confessed that this view is not without some foundation, but these are days of rapid transportation and the student starts early on his mathematical journey. The question as regards the extent of explored country which should be studied before entering unexplored regions is a very perplexing one. A lifetime would not suffice to become acquainted with all the known fields, and there are those who are so much attracted by the explored regions that they do not find time or courage to enter into the unknown.

In 1840 C. G. J. Jacobi used an illustration, in a letter⁴ to his brother, which may serve to emphasize an important point. He states that at various times he had tried to persuade a young man to begin research in mathematics, but this young man always excused himself on the ground that he did not yet know enough. In answer to this statement Jacobi asked this man the following question: Suppose your family would wish you to marry, would you then

²"Der Urquell aller Mathematik sind die ganzen Zahlen, Minkowski, *Diophantische Approximation*," 1907, preface.

³"Briefwechsel zwischen C. G. J. Jacobi und M. H. Jacobi," 1907, p. 64.

¹"Encyclopédie des sciences mathématiques," Vol. I., part 1, 1904, p. 2.

also reply that you did not see how you could marry now, as you had not yet become acquainted with *all* the young ladies?

In connection with this remark by Jacobi we may recall a remark by another prominent German mathematician who also compared the choice of a subject of research with marriage. In the "Festschrift zur Feier des 100 Geburtstages Eduard Kummer," 1910, page 17, Professor Hensel states that Kummer declined, as a matter of principle, to assign to students a subject for a doctor's thesis, saying that this would seem to him as if a young man would ask him to recommend to him a pretty young lady whom he should marry.

While it may not be profitable to follow these analogies into details, it should be stated that the extent to which a subject has been developed does not necessarily affect adversely its desirability as a field of research. The greater the extent of the development the more frontier regions will become exposed. The main question is whether the new regions which lie just beyond the frontier are fertile or barren. This question is much more important than the one which relates to the distance that must be traveled to reach these new fields. Moreover, it should be remembered that mathematics is n -dimensional, n being an arbitrary positive integer, and hence she is not limited, in her progress, to the directions suggested by our experiences.

If we agree with Minkowski that the integers are the source of all mathematics⁵ we should remember that the numbers which have gained a place among the integers of the mathematician have increased

⁵ This view was expressed earlier by Kronecker, who was the main founder of the school of mathematicians who aim to make the concept of the positive integers the only foundation of mathematics. Cf. Klein und Schimmack, "Der mathematische Unterricht an den hoeheren Schulen," 1907, p. 175.

wonderfully during recent times. According to the views of the people who preceded Gauss, and according to the elementary mathematics of the present day, the integers may be represented by points situated on a straight line and separated by definite fixed distance. On the other hand, the modern mathematician does not only fill up the straight line with algebraic integers, placing them so closely together that between any two of them there is another, but he fills up the whole plane equally closely with these integers. If our knowledge of mathematics had increased during the last two centuries as greatly as the number of integers of the mathematician we should be much beyond our present stage. The astronomers may be led to the conclusion that the universe is probably finite from the study of the number of stars revealed by telescopes of various powers, but the mathematician finds nothing which seems to contradict the view that his sphere of action is infinite.

From what precedes one would expect that the number of fields of mathematical research appears unlimited and this may serve to furnish a partial explanation of the fact that it seems impossible to give a complete definition of the term mathematics. If the above view is correct we have no reason to expect that a complete definition of this term will ever be possible, although it seems possible that a satisfactory definition of the developed parts may be forthcoming.⁶

Among the various fields of research those which surround a standing problem are perhaps most suitable for a popular exposition, but it should not be inferred that these are necessarily the most important points of attack for the young inves-

⁶ Bôcher discussed some of the proposed definitions in the *Bulletin of the American Mathematical Society*, Vol. II. (1904), p. 115.

tigator. On the contrary, one of the chief differences between the great mathematician and the poor one is that the former can direct his students into fields which are likely to become well known in the near future, while the latter can only direct them to the well-known standing problems of the past, whose approaches have been tramped down solid by the feet of the mediocre, who are often even too stupid to realize their limitations. The best students can work their way through this hard crust, but the paddle of the weaker ones will only serve to increase its thickness if it happens to make any impression whatever.

It would not be difficult to furnish a long list of standing mathematical problems of more or less historic interest. Probably all would agree that the most popular one at the present time is Fermat's greater theorem. In fact, this theorem has become so popular that it takes courage to mention it before a strictly mathematical audience, but it does not appear to be out of place before a more general audience like this.

The ancient Egyptians knew that $3^2 + 4^2 = 5^2$ and the Hindus knew several other such triplets of integers at least as early as the fourth century before the Christian era.⁷ These triplets constitute positive integral solutions of the equation

$$x^2 + y^2 = z^2.$$

Pythagoras gave a general rule by means of which one can find any desired number of such solutions, and hence these triplets are often called Pythagorean numbers. Another such rule was given by Plato, while Euclid and Diophantus generalized and extended these rules.

Fermat, a noted French mathematician of the seventeenth century, wrote on the

⁷Lietzmann, "Der Pythagoreische Lehrsatz," 1912, p. 52.

margin of a page of his copy of Diophantus the theorem that it is impossible to find any positive integral solution of the equation

$$x^n + y^n = z^n \quad (n > 2).$$

He added that he had discovered a wonderful proof of this theorem, but that the margin of the page did not afford enough room to add it.⁸ This theorem has since become known as Fermat's greater theorem and has a most interesting and important history, which we proceed to sketch.

About a century after Fermat had noted this theorem Euler (1707-1783) proved it for all the cases when n is a multiple of either 3 or 4, and, during the following century, Dirichlet (1805-1859) and Legendre (1752-1833) proved it for all the cases when n is a multiple of 5. The most important step towards a general proof was taken by Kummer (1810-1893), who applied to this problem the modern theory of algebraic numbers and was thus able to prove its truth for all multiples of primes which do not exceed 100 and also for all the multiples of many larger primes.

The fact that such eminent mathematicians as Fermat, Euler, Dirichlet, Legendre and Kummer were greatly interested in this problem was sufficient to secure for it considerable prominence in mathematical literature, and several mathematicians, including Dickson, of Chicago, succeeded in extending materially some of the results indicated above. The circle of those taking an active interest in the problem was suddenly greatly enlarged, a few years ago, when it became known that a prize of 100,000 Marks (about \$25,000) was awaiting the one who could present the first complete solution. This amount was put in trust of the Göttingen Gesellschaft der

⁸Fermat's words are as follows: "Cujus rei demonstrationem mirabilem sane detexi. Hanc marginis exiguitas non caperet."

Wissenschaften by the will of a deceased German mathematician named Wolfskehl, and it is to remain open for about a century, until 2007, unless some one should successfully solve the problem at an earlier date.

It is too early to determine whether the balance of the effects of this prize will tend towards real progress. One desirable feature is the fact that the interest on the money is being used from year to year to further important mathematical enterprises. A certain amount of this has already been given to A. Wieferich for results of importance towards the solution of Fermat's problem, and other amounts were employed to secure at Göttingen courses of lectures by Poincaré and Lorentz.

What appears as a bad effect of this offered prize is the fact that many people with very meager mathematical training and still less ability are wasting their time and money by working out and publishing supposed proofs. The number of these is already much beyond 1,000 and no one can foresee the extent to which this kind of literature will grow, especially if the complete solution will not be attained during the century. A great part of this waste would be eliminated if those who would like to test their ability along this line could be induced to read, before they offer their work for publication, the discussion of more than 100 supposed proofs whose errors are pointed out in a German mathematical magazine called *Archiv der Mathematik und Physik*, published by B. G. Teubner, of Leipzig. A very useful pamphlet dealing with this question is entitled, "Ueber das letzte Fermatische Theorem, von B. Lind," and was also published by B. G. Teubner, in 1910.

A possible good effect of the offered prize is that it may give rise to new developments and to new methods of attack. As

the most successful partial solution of the problem was due to the modern theory of algebraic numbers, one would naturally expect that further progress would be most likely to result from a further extension of this theory, or, possibly, from a still more powerful future theory of numbers. If such extensions will result from this offer they will go far to offset the bad effect noted above, and they may leave a decided surplus of good. Such a standing problem may also tend to lessen mathematical idolatry, which is one of the most serious barriers to real progress. We should welcome everything which tends to elevate the truth above our idols formed by men, institutions or books.

In view of the fact that the offered prize is about \$25,000 and that lack of marginal space in his copy of Diophantus was the reason given by Fermat for not communicating his proof, one might be tempted to wish that one could send credit for a dime back through the ages to Fermat and thus secure this coveted prize and the wonderful proof, if it actually existed. This might, however, result more seriously than one would at first suppose; for if Fermat had bought on credit a dime's worth of paper even during the year of his death, 1665, and if this bill had been drawing compound interest at the rate of six per cent. since that time, the bill would now amount to more than seven times as much as the prize. It would therefore require more than \$150,000, in addition to the amount of the prize, to settle this bill now.

While it is very desirable to be familiar with such standing problems as Fermat's theorem, they should generally be used by the young investigator as an indirect rather than as a direct object of research. Unity of purpose can probably not be secured in any better way than by keeping

in close touch with the masters of the past,⁹ and this unity of purpose is almost essential to secure real effective work in the immense field of mathematical endeavor. As a class of problems which are much more suitable for direct objects of research on the part of those who are not in close contact with a master in his field, we may mention the numerous prize subjects which are announced from year to year by foreign academies.

Among the learned societies which announce such subjects the Paris Academy of Sciences is probably most widely known, but there are many others of note. The subjects announced annually by these societies cover a wide range of mathematical interests, but they are frequently beyond the reach of the young investigator.¹⁰ It is very easy to obtain these subjects, since they generally appear in the "notes" of many mathematical journals. In our country the *Bulletin of the American Mathematical Society* is rendering very useful service along this and many other lines. While some of these subjects are very general, there are others which indicate clearly the particular difficulties which must be overcome before further progress in certain directions seems possible and hence these subjects deserve careful study, especially on the part of the younger investigators.

As long as one is completely guided, in selecting subjects for research, by the standing problems or by the subjects announced by learned bodies and those proposed individually by prominent investigators, one is on safe ground. Real progress along any of these lines is welcomed by our

⁹ Darboux, *Bulletin des Sciences Mathématiques*, Vol. 32 (1908), p. 107.

¹⁰ For solutions of such problems in pure mathematics by Americans, see *Bulletin of the American Mathematical Society*, Vol. 7 (1901), p. 190; Vol. 16 (1910), p. 267.

best journals, as such progress can easily be measured, and it fits into a general trend of thought which is easily accessible in view of the many developed avenues of approach. Notwithstanding these advantages, the real investigator should reach the time when he can select his own problems without advice or authority; when he feels free to look at the whole situation from a higher point of view and to assume the responsibility of an independent choice, irrespective of the fact that an independent choice may entail distrust and misgivings on the part of many who would have supported him nobly if he had remained on their plane.

In looking at the whole situation from this higher point of view many new and perplexing questions confront us. Why should the developments of the past have followed certain routes? What is the probability that the development of the territory lying between two such routes will exhibit new points of contact and greater unity in the whole development? What should be some guiding principles in selecting one rather than another subject of investigation? What explanation can we give for the fact that some regions bear evidences of great activity in the past but are now practically deserted, while others maintained or increased their relative popularity through all times?

One of the most important tests that can be applied to a particular mathematical theory is whether it serves as a unifying and clarifying principle of wide applications. Whether these applications relate to pure mathematics only or to related fields seems less important. In fact, the subjects of application may have to be developed. If this is the case, it is so much the better provided always that the realm of thought whose relations are exhibited by the theory is extensive and that the relations are of such a striking character as to

appeal to a large number of mathematical intellects of the present or of the future. Some isolated facts may be of great interest, but as long as they are isolated they have little or no real mathematical interest. One object of mathematics is to enable us to deal with infinite sets with the same ease and confidence as if they were individuals. In this way only can our finite mind treat systematically some of the infinite sets of objects of mathematical thought.

In comparatively recent years the spirit of organization has made itself felt among mathematicians with rapidly increasing power, and it has already led to many important results. Beginning with small informal organizations in which the social element was often most prominent, there have resulted large societies, national and even international, with formal organizations and with extensive publications. In reference to one of these early organizations, the mathematical society of Spitalfields in London, which lasted for more than a century (1717-1845), it is said that each member was expected to come to the meetings with his pipe, his mug and his problem.¹¹

The modern mathematical society is dominated by a different spirit. It generally supports at least one organ for publication, and scholarly publicity develops scholarly cooperation as well as scholarly ambitions. This cooperation has led to movements which could not have been undertaken by a few individuals. One may recall here the *Revue Semestrielle*, published under the auspices of the Amsterdam Mathematical Society; the extensive movement to examine and compare methods and courses of mathematical instruction in various countries,

inaugurated at the fourth international congress, held at Rome in 1908; and, especially the great mathematical encyclopedias whose start was largely influenced by the support of the deutschen Mathematiker-Vereinigung as expressed at the Vienna meeting in 1894. The French edition of the latter work, which is now in the course of publication, is expected to include thirty-four large volumes, besides those which are to be devoted to questions of the philosophy, the teaching and the history of mathematics.

These encyclopedias and other large works of reference are doing much to expedite travel in the mathematical field. In fact, it would probably not be exaggerating if we should say that by these encyclopedias alone the distances, in time and effort, between many points of the mathematical field have been cut in two. In this connection, it may be fitting to recall, with a deep sense of obligation, the great work which is being done by the Royal Society of London—not only for mathematics, but also for a large number of other sciences—in providing bibliographical aids on a large scale. If the increase in knowledge will always be attended by a corresponding increase in means to learn readily what is known, even the young investigator of the future will have no reason to regret the extent of the developments. On the contrary, these should make his task easier, since they furnish such a great richness of analogies and of tried methods of attack.

The last two or three decades have witnessed a great extension of mathematical research activity. As a result of this we have a large number of new mathematical societies. A few of the most recent ones are as follows: Calcutta Mathematical Society (1908), Manchester Mathematical Society (1908), Scandinavian Congress of Mathematicians (1909), Swiss Mathemat-

¹¹ "Es wurde von jedem erwartet, dass er seine Pfeife, seinen Krug und sein Problem mitbringe." Cantor, "Vorlesungen ueber Geschichte der Mathematik," Vol. 4, 1908, p. 59.

ical Society (1910), Spanish Mathematical Society (1911) and the Russian Congress of Mathematicians (1912). In Japan a new mathematical periodical, called *Tôhoku Mathematical Journal*, was started in 1911, and a few years earlier the *Journal of the Indian Mathematical Society* was started at Madras, India. The Calcutta Mathematical Society and the Spanish Mathematical Society have also started new periodicals during the last two or three years.

While there has been a very rapid spread of mathematical activity during recent years, it must be admitted that the greater part of the work which is being done in the new centers is quite elementary from the standpoint of research. The city of Paris continues to hold its preeminent mathematical position among the cities of the world; and Germany, France and Italy continue to lead all other countries in regard to the quality and the quantity of research in pure mathematics.

Although America is not yet doing her share of mathematical research of a high order, we have undoubtedly reached a position of respectability along this line, and it should be easier to make further progress. Moreover, our material facilities are increasing relatively more rapidly than those of the countries which are ahead of us, and hence many of our younger men start under very favorable conditions. Unfortunately, there is not yet among us a sufficiently high appreciation of scholarly attainments and scientific distinction. The honest and outspoken investigator is not always encouraged as he ought to be and the best positions do not always seek the best man. I coupled outspoken with investigator advisedly, since research of high order implies liberty and scorns shams, especially shams relating to scholarship. Even along these lines there seems to be encouraging progress, and this progress may reasonably

be expected to increase with the passing of those who belong to the past in spirit and attainments. What appears to be a very serious element in our situation is the fact that the American university professor does not yet seek and safeguard his freedom with the zeal of his European colleague. It is too commonly assumed that loyalty implies lying.

The investigators in pure mathematics form a small army of about two thousand men and a few women.¹² The question naturally arises what is this little army trying to accomplish. A direct answer is that they are trying to find and to construct paths and roads of thought, which connect with or belong to a network of thought roads commonly known as mathematics. Some are engaged in constructing trails through what appears an almost impassable region while others are widening and smoothing roads which have been traveled for centuries. There are others who are engaged in driving piles in the hope of securing a solid foundation through regions where quicksand and mire have combined to obstruct progress.

A characteristic property of mathematics is that by means of certain postulates its

¹² Between five and ten per cent. of the members of the American Mathematical Society are women, but the per cent. of women in the leading foreign mathematical societies is much smaller. Less than one per cent. of the members of the national mathematical societies of France, Germany and Spain are women, according to recent lists of members. The per cent. of important mathematical contributions by women does not appear to be larger, as a rule, than that of their representation in the leading societies. The list of about three hundred collaborators on the great new German and French mathematical encyclopedias does not seem to include any woman. Possibly women do not prize sufficiently intellectual freedom to become good mathematical investigators. Some of them exhibit excellent ability as mathematical students.

thought roads have been proved to be safe and they always lead to some prominent objective points. Hence they primarily serve to economize thought. The number of objects of mathematical thought is infinite, and these roads enable a finite mind to secure an intellectual penetration into some parts of this infinitude of objects. It should also be observed that mathematics consists of a *connected* network of thought roads, and mathematical progress means that other such connected or connecting roads are being established, which either lead to new objective points of interest or exhibit new connections between known roads.

The network of thought roads called mathematics furnishes a very interesting chapter in the intellectual history of the world, and in recent years an increasing number of investigators have entered the field of mathematical history. The results are very encouraging. In fact, there are very few other parts of mathematics where the progress during the last twenty years has been as great as in this history. This progress is partly reflected by special courses in this subject in the leading universities of the world. While the earliest such course seems to have been given only about forty years ago, a considerable number of universities are now offering regular courses in this subject, and these courses have the great advantage that they establish another point of helpful contact between mathematics and other fields.

Mathematical thought roads may be distinguished by the facts that by means of certain assumptions they have been *proved* to lead safely to certain objective points of interest, and each of them connects, at least in one point, with a network of other such roads which were called mathematics, *μαθηματά* by the ancient Greeks. The mathematical investigator of the present day is

pushing these thought roads into domains which were totally unknown to the older mathematicians. Whether it will ever be possible to penetrate all scientific knowledge in this way and thus to unify all the advanced scientific subjects of study under the general term of mathematics, as was the case with the ancient Greeks,¹³ is a question of deep interest.

The scientific world has devoted much attention to the collection and the classification of facts relative to material things, and has secured already an immensely valuable store of such knowledge. As the number of these facts increases, stronger and stronger means of intellectual penetration are needed. In many cases mathematics has already provided such means in a large measure; and, judging from the past, one may reasonably expect that the demand for such means will continue to increase as long as scientific knowledge continues to grow. On the other hand, the domain of logic has been widely extended through the work of Russell, Poincaré and others; and Russell's conclusion that any false proposition implies all other propositions whether true or false is of great general interest.

During the last two or three centuries there has been a most remarkable increase in facilities for publication. Not only have academies and societies started journals for the use of their members, but numerous journals inviting suitable contributions from the public have arisen. The oldest of the latter type is the *Journal des Sçavans*, which was started at Paris in 1665, while the *Transactions of the Royal Society of London*, started in the same year, should probably be regarded as the oldest of the former type. These journals have done an

¹³ The term mathematics was first used with its present restricted meaning by the Peripatetic School. Cantor, "Vorlesungen über Geschichte der Mathematik," Vol. I. (1907), p. 216.

inestimable amount of good for the growth of knowledge and the spread of the spirit of investigation. At the present time more than 2,000 articles which are supposed to be contributions to knowledge in pure mathematics appear annually in such periodicals. In addition to these there is a growing annual list of books.

The great extent of the fields of mathematics and the rapid growth of this literature have made it very desirable to secure means of judging more easily the relative merit of various publications. Along this line our facilities are still very meager and many serious difficulties present themselves. In America we have the book reviews and the indirect means provided by the meetings of various societies and by such publications as the "American Men of Science."

The most important aid to judge contemporaneous work is furnished by a German publication known as the *Jahrbuch über die Fortschritte der Mathematik*. In this work there appear annually about 1,000 pages of reviews of books and articles published two or three years earlier. These reviews are prepared by about 60 different mathematicians who are supposed to be well prepared to pass judgment on the particular books and articles which they undertake to review. While these reviews are of very unequal merit, they are rendering a service of the greatest value.

The main object of such reviews is to enable the true student to learn easily what progress others are making, especially in his own field and in those closely related thereto. They serve, however, another very laudable purpose in the case that they are reliable. We have the pretender and the unscrupulous always with us, and it is almost as important to limit their field of operation as to encourage the true investigator. "Companions in zealous research"

should be fearless in the pursuit of truth and in the disclosure of falsehood, since these qualities are essential to the atmosphere which is favorable to research.

While the mathematical investigator is generally so engrossed by the immediate objects in view that he seldom finds time to think of his services to humanity as a whole, yet such thoughts naturally come to him more or less frequently, especially since his direct objects of research seldom are well suited for subjects of general conversation. If these thoughts do come to him they should bring with them great inspiration. Who can estimate the amount of good mathematics has done and is doing now? If all knowledge of mathematics could suddenly be taken away from us there would be a state of chaos, and if all those things whose development depended upon mathematical principles could be removed, our lives and thoughts would be pauperized immeasurably. This removal would sweep away not only our modern houses and bridges, our commerce and landmarks, but also most of our concepts of the physical universe.

Some may be tempted to say that the useful parts of mathematics are very elementary and have little contact with modern research. In answer we may observe that it is very questionable whether the ratio of the developed mathematics to that which is finding direct application to things which relate to material advantages is greater now than it was at the time of the ancient Greeks. The last two centuries have witnessed a wonderful advance in the pure mathematics which is commonly used.¹⁴ While the advance in the extent

"In 1726, arithmetic and geometry were studied during the senior year in Harvard College. Natural philosophy and physics were still taught before arithmetic and geometry. Cajori, "The Teaching and History of Mathematics in the United States," 1890, p. 22.

of the developed fields has also been rapid, it has probably not been relatively more rapid. Hence the mathematical investigator of to-day can pursue his work with the greatest confidence as regards his services to the general uplift both in thought and in material betterment of the human race. All of his real advances may reasonably be expected to be enduring elements of a structure whose permanence is even more assured than that of granite pillars.

UNIVERSITY OF ILLINOIS

SCIENTIFIC DISTRIBUTION OF GRADES AT REED COLLEGE

A SCIENTIFIC rather than a personal basis for awarding grades in courses of study, if grades are to be used at all, together with definite credit for quality as well as for quan-

tute one vague expression for another. Without scientific definition, any set of symbols is inevitably used in personal, variable, erratic ways. To award scholarships, degrees and other honors, as if an *A* in one course represented the same distinction as an *A* in another course is to administer the curriculum on a patently false assumption.¹

Until all school work can be measured by scales, made up of units that are equal in a defined sense, the best available grading is one of relative position in a series. The nearest approach to such a scientific basis for awarding college credits appears to be a distribution following the normal probability curve, skewed to take account of the effect of selecting the student body.

The Reed College system is shown in the illustration. The outer curve, partly dotted, is the normal probability curve. The inner curve, partly coinciding with the other, shows

tity of work, seems desirable, especially for institutions that are more than theoretically devoted to scholarship, and that are willing to make what sacrifices such ideals may involve.

The common grades *A* to *E* have no defined meaning. To call them such and such a per cent. of an undefined something is to substi-

¹It is impossible, here, to give a detailed explanation of the "credit for quality" system and the scientific distribution of grades adopted by Reed College. The underlying principles of both are fully explained in chapters 12 and 13 of the "Administration of the College Curriculum," Houghton Mifflin Company, 1911. "The Distribution of Grades on a Scientific Basis" is presented in *Popular Science Monthly* for April, 1911.

the result of selecting the student body, and would be vertical at the right side if it were possible to perfect the selection so as to exclude all below a certain standard and admit all above that standard.

Reed College uses ten grades. Ten, rather than any other number, are used, because tests by approved statistical and psychological methods show that fewer grades are inadequate to designate readily discernible differences, and many more grades can not be used with intelligent discrimination. The definitions of these grades have a scientific basis. Grades 1-5 indicate that a student stands in the upper half of an average class; grades 6-10 indicate that he is in the lower half. For example, 2 designates the work which will be done (in the long run) by the best 5 per cent. of all students, and 6 the work done by that quarter of an average class standing just below the middle. These particular percentages were chosen somewhat arbitrarily for the sake of convenient round numbers, but they correspond fairly well to the distribution shown in the probability curve as skewed from normal by the selection of students.

Grade 1 is rarely given, representing a degree of excellence attainable by not more than one student in four or five hundred; similarly, grade 10 records correspondingly bad failures. The lowest grade called passable is 8, which covers all cases where credit is granted conditionally or upon the satisfaction of some special requirement; 9 is for ordinary cases of failure.

It will be observed that the symbol 1 of the Reed College scale is a grade of real distinction, as the *A* of the usual scale is not; and that even the 3 of the Reed College scale represents quite as much distinction as the *A* if the latter grade were obtained by 15 per cent. of a class.

The grades, however, can not be interpreted in qualitative terms, as good, poor, *A*, *C*, 90 per cent.; nor do they designate rank in the particular class. They show the group in which the student would appear if the classes of several years were subdivided as indicated above.

Such a definition will not make a "2" = "2" as regards the actual quality of work done by the student, since this is a matter not only of the student's relative standing in the subject, but also of the actual standards set for that subject. But despite this, for courses of the same general sort (as introductory courses without prerequisites, whether coming in freshman or senior year), the relative rank in an average class seems to be the best available criterion of the student's merits.

In adopting the Reed College System, we attempted to divide the base line of the normal probability curve into equal parts; but we found this awkward, as grade 2 would then fall to but $1\frac{1}{2}$ per cent. of the students. We then tried (each side of the median) a distribution of 20 per cent., 15 per cent., 10 per cent., 5 per cent., which corresponds to equal bases for grades 4, 5, 6, 7 with somewhat longer bases for 3 and 8, and much longer ones for 2 and 9. This distribution seemed more convenient. We changed the distribution on the lower side, however, to 25 per cent., 15 per cent., 6 per cent., 4 per cent., to allow for skewing of the curve due to the influence of selection. What sort of divisions of the base line this requires no one can say without knowing the exact shape of the skewed curve (which depends on how effective the selective cut is), and knowing also how far the new median has been moved above the median in the normal curve (which depends on what area was cut off, according to the standard of selection). In using unequal divisions of the base line, therefore, we make a choice of percentages which is somewhat arbitrary, except that it follows roughly the sort of distribution in the skewed curve with equal base divisions.

With such a basis for grading students in their college courses, it is possible to give a definite and just reward for high scholarship by allowing a course completed with high credit to count more toward a degree than a course completed with lower credit. Such a plan for counting quality has the great advantage of enabling the students who do the best work to graduate in less than the normal

time, without tempting them to take more subjects in a given year than they can creditably pursue.

WILLIAM T. FOSTER

SCIENTIFIC NOTES AND NEWS

By the untimely death of Wilbur Wright the country loses an inventor of distinction, whose great achievement in the development of the aeroplane gives him high rank among those who have contributed to the practical applications of science.

DR. WILLIAM McMICHAEL WOODWORTH, of the Harvard Museum of Comparative Zoology and the author of important contributions to zoology, has died at the age of forty-eight years.

VICE-PRESIDENT THOMAS JONATHAN BURRILL and Comptroller Samuel Walker Shattuck, of the University of Illinois, will retire from active service at the end of the present academic year, having been granted special retiring allowances by the Carnegie Foundation for the Advancement of Teaching. Both of them have been with the university since its foundation in 1868, and have been potent factors in its upbuilding. Dr. Burrill has served as professor, dean, vice-president and acting president and has done notable research work in botany and bacteriology. Professor Shattuck has served as professor of mathematics, vice-president and comptroller.

DR. HENRY T. EDDY, head of the department of mathematics and mechanics at the University of Minnesota and dean of the graduate school, will retire from active service under the terms of the Carnegie Foundation.

PROFESSOR THEODORE W. RICHARDS, of the department of chemistry of Harvard University, lectured at the University of Michigan upon "Atomic Compressibility" on May 16. On May 17 he was awarded the Willard Gibbs medal by the Chicago Section of the American Chemical Society, and delivered an address upon "Atomic Weights."

THE death of Lord Lister having created a vacancy in the membership of the Royal Society of Science, Upsala, Sir Victor Horsley, F.R.S., has been elected his successor.

THE Société Astronomique de France has, says *The Observatory*, lately taken advantage of two anniversaries to pay honor to the founder and past-president of the society. January 28 last was the twenty-fifth anniversary of the founding of the society, and this year is the fiftieth of M. Flammarion's career as an astronomical writer, for his first great work, "La Pluralité des Mondes habités," was published in 1862. The actual ceremony took place in the large hall of the Sociétés Savants on the evening of February 26, which happened to be M. Flammarion's seventieth birthday, so that three anniversaries were celebrated.

As a memorial of Professor Ralph S. Tarr a volume is to be published consisting of essays on physiographic and geographic subjects, the work of men trained by him. A committee has been named to take charge of the preparation and publication of the volume. This committee has asked Dr. Frank Carney, professor of geology in Denison University, to edit the work.

THE completion by Rudolf von Jaksch of twenty-five years as professor of internal medicine at Prague was celebrated recently. The *Prager med. Wochenschrift* issued a special number in his honor and a *Festschrift* was presented to him.

COLONEL SIR DAVID BRUCE, C.B., F.R.S., has been promoted to the rank of surgeon general in the British Army, in consideration of his eminent services to the cause of science. Sir David Bruce is at present at the head of the Sleeping Sickness Commission appointed by the government, with the advice of the Royal Society, to continue the study of the disease in Nyasaland.

A GRANT of \$140 from the C. M. Warren Fund of the American Academy of Arts and Sciences has been made to Professor Arthur B. Lamb for work upon the rhodiumamines.

HARRY MILES JOHNSON, Ph.D. (Hopkins '12), has been appointed psychological assistant in the physical laboratory of the National Electric Lamp Association, Cleveland, Ohio.

THE American Road Builders' Association gave a dinner at the Hotel Astor, New York

City, on June 5, in honor of W. Rees Jeffreys, Esq., secretary of the road board of England and honorary general secretary of the local organizing committee of the third International Road Congress to be held in London in June, 1913.

PROFESSOR THOMAS A. JAGGAR, JR., professor of geology in the Massachusetts Institute of Technology, has been granted leave of absence for five years, and sails for Honolulu early this month to take charge of the Volcano Laboratory of the institute on the crater of Kilauea. Drs. A. L. Day and E. S. Shepherd, of the Carnegie Institution, are now in Hawaii and expect to spend the summer in investigations of optical pyrometry and spectroscopic analysis.

PROFESSOR ELLSWORTH HUNTINGTON, of Yale University, will this year carry further the work of investigating climatic changes during the last two or three thousand years which he undertook last summer under the auspices of the Carnegie Institute of Washington. Accompanied by Professor H. S. Canby, he has left for California, where he will be joined by a party of four or five students and others from the University of California. They will proceed into the Sierra Nevada Mountains in the King's River section south of Yosemite, where they will spend two months measuring trees.

PROFESSOR ALFRED DODGE COLE, head of the department of physics at Ohio State University, has been granted leave of absence for the college year 1912-13. It is probable that he will spend four months in research at the National Bureau of Standards, Washington, and a semester similarly at the University of Berlin.

DR. ALBERT BUSHNELL HART, professor of the science of government at Harvard University, is at present lecturing at Colorado College in Colorado Springs as exchange professor. He is giving lectures on American history (1850-1865), on American biography, and on the Orient (Japan, China, Philippines, India).

THE Harrington lectures arranged by the medical faculty of the University of Buffalo

will be delivered in Alumni Hall by Dr. Ludwig Hektoen, of Chicago, on May 28 to 31, on "Immunity."

PROFESSOR C. A. ADAMS, of Harvard University, gave a lecture "On the Place of the Engineer in Modern Society," at the University of Vermont on the evening of May 15, and a lecture on "The Synchronous Motor," on the morning of May 16.

THE Illinois State Association of Operating Engineers met at the University of Illinois on May 24. Addresses were given by President James, Dean W. F. Goss, of the College of Engineering, Professor Parr and Professor Bartow, of the department of chemistry.

A CONFERENCE will be held at the Graduate School of Agriculture, Lansing, Mich., on July 24, to discuss the formulation of standard rations for experimental work in determining the comparative value of feed stuffs. Mr. B. H. Rawl, chief of the dairy division, U. S. Department of Agriculture, President H. J. Waters, of the Kansas Agricultural College, Professor C. H. Eckles, of the Missouri Experiment Station, and other leading workers in this field are expected to be present and lead the discussion.

ALL persons interested in the scientific section of the American Pharmaceutical Association are requested to notify any of the officers of the section of the title or titles of the paper or papers that they contemplate presenting before the section at the annual meeting of the Association at Denver, Colorado, August 19-24 inclusive, 1912. Original papers of scientific interest, whether directly of pharmaceutical interest or not will be considered by the committee. The committee on scientific papers consists of W. O. Richtmann, *chairman*; F. P. Stroup, *secretary*, 145 North 10th St., Philadelphia, Pa.; F. R. Eldred, *associate*, 3323 Kenwood Ave., Indianapolis, Ind.

THE second annual meeting of the American Climatological Association will be held in Hartford, Conn., June 10-12, under the presidency of Dr. A. D. Blackader, Montreal.

THE conference of bath officials and others interested in public baths, held at New York City, on May 14 and 15, resulted in the or-

ganization of the American Association for Promoting Hygiene and Public Baths. Dr. Simon Branch, professor in the medical department of Columbia University, who has for nearly twenty years led the movement for free public baths, was elected president, and Dr. William H. Hale, permanent secretary. The annual meeting will be held on the second Tuesday of May, the next meeting being at Baltimore, May 13, 1913. The membership fee is one dollar a year and all persons of good character are eligible for membership.

A CABLEGRAM received at the Harvard College Observatory from Kiel states that a spectrogram of Enebos Nova obtained by Kuestner at Bonn shows "dark lines uranium radium emanation."

WE learn from the London *Times* that Messrs. Sotheby sold, on May 17, the scientific books of the late Sir Joseph Dalton Hooker, among which were several presentation copies, whilst many were with valuable MS. notes by the late owner. A set of Hooker's *Icones Plantarum*, 1837-1911, 30 volumes—£67 (Wesley); Edwards's *Botanical Register*, 1815-47, 33 volumes—£26 (Muller); and a collection of books on the "Flora" of the Antarctic regions, New Zealand, etc., in nine volumes—£123 (Wesley). The late Dr. Joseph F. Payne's property included a slightly defective copy of Apuleius Platonius, "Herbarium," Rome, 1488, the earliest printed book with figures of plants—£55 (Leighton); J. Milton, "Areopagitica," 1644, the very rare first edition, one page slightly cut into—£21 (Barnard); and Joannem de Cuba, "Tractatus de Herbis," etc., 1491, with numerous woodcuts of plants and animals, slightly defective—£35 (Quaritch). The two days' sale of books realized £1,488 14s.

ACCORDING to the *Journal* of the American Medical Association the births for 1910 were 35,119 and for 1911, 69,098 below the average for the decade 1901 to 1910, while the number of marriages in the first year was 10,154 and in the latter 20,897 above the average in that period. It is therefore evident that the fertility of married women has shown a considerable decrease. For each 1,000 of the pop-

ulation there occurred in 1911 30.2 births as compared with 31.5 in 1910, 32.7 in 1909, 33.7 in 1908 and 37.4 in 1901, so that in ten years the birth rate has dropped by 7.2 per thousand. The number of deaths in 1911 was 18.1 per thousand, as contrasted with 16.9, 17.9, 18.9 and 21.7 in the four preceding years. According to these figures, the excess of births for 1911 was 12.1, as compared with 14.6 in 1910, 14.8 in 1909 and 1908 and 15.7 in 1901.

UNIVERSITY AND EDUCATIONAL NEWS

NEARLY \$1,000,000 was appropriated by the General Education Board at its meeting on May 24. \$250,000 is given to the George Peabody College for Teachers at Nashville, Tenn., for the establishment of the Seaman A. Knapp School of Country Life. The other colleges awarded conditional appropriations are: Beloit College, Beloit, Wis., \$100,000; Coe College, Cedar Rapids, La., \$100,000; McAlester College, St. Paul, Minn., \$50,000; University of Rochester, Rochester, N. Y., \$200,000. The sum of \$210,000 was set aside for demonstration work in agriculture in the southern states, for professors of secondary education in state universities of the south, and to aid the work of Negro education in the south.

PROFESSOR OTIS F. RANDALL, who holds the chair of mechanics and mechanical drawing at Brown University, has been appointed dean of the university to succeed Professor Alexander Meiklejohn, who is to become president of Amherst College.

DR. GEORGE DOCK has resigned the deanship of the medical department of Washington University, St. Louis. Dr. Dock will continue as professor of medicine.

DR. DAVID RIESMAN and Dr. Joseph Sailer have been elected professors of clinical medicine in the medical department of the University of Pennsylvania, in succession to the late Dr. John H. Musser. Dr. Richard M. Pearce occupies the John Herr Musser professorship of medical research.

VICTOR C. MYERS, Ph.D. (Yale, '09), has been appointed professor of pathological chemistry, and has taken charge of the new labora-

tory for pathological chemistry recently opened at the New York Post-Graduate Medical School and Hospital.

PROFESSOR WILLIAM E. BROOKE, of the College of Engineering, University of Minnesota, has been appointed to fill the vacancy caused by the retirement of Dr. H. T. Eddy, the head of the department of mathematics and mechanics. Dr. William F. Holman takes the place made vacant by the retirement of Dr. Arthur E. Haynes, from the department of mathematics.

THROOP POLYTECHNIC INSTITUTE, of Pasadena, California, is materially enlarging its department of chemistry with a view to keeping in touch with the industrial development of southern California, especially in connection with the oil industry. Dr. Richard Sidney Curtiss, Ph.B. (Yale, '88), Ph.D. (Würzburg, '92), now professor of organic chemistry at the University of Illinois, has been appointed professor of organic chemistry and research associate. Charles Andrew Brautlecht, Ph.B. (Yale, '06), now doing graduate work at Yale, has been appointed instructor in chemistry and physics. William Ruthven Flint, A.B. (Yale, '98), Ph.D. (Yale, '09), continues in the department as professor of inorganic and analytical chemistry.

OWING to the rapidly growing interest in the science of chemistry and the recognition of its importance in the development of the state resources, the president and regents of the University of California have provided for the enlargement and reorganization of the department of chemistry. In addition to the present staff, the following appointments have been made: Professor Gilbert N. Lewis, of the Massachusetts Institute of Technology, professor of chemistry and chairman of the department; Professor William C. Bray, of the same institution, and Professor Richard C. Tolman, of the University of Cincinnati, assistant professors of chemistry. Several additional instructorships and assistantships have also been created. Owing to the absence of Professor Morgan, the course in elementary chemistry will be in charge of Professor Harry W. Morse, who has received for this purpose

leave of absence for one year from Harvard University. Professor Edmond O'Neill has been appointed director of the chemical laboratory. Owing to the crowded condition of the present laboratory, a new building on the site provided in the Hearst plans will soon be begun. In the mean time, a temporary building is being constructed, and will contain a laboratory of physical chemistry, several offices and research laboratories and shops for mechanic and glass blower. Much attention will be given to the development of advanced study and research. A considerable number of men, several of whom come from other institutions, will enter next term as candidates for the doctorate. Advanced seminars will be offered in organic, inorganic and physical chemistry.

DISCUSSION AND CORRESPONDENCE

THE HEATING IN THE CULEBRA CUT

TO THE EDITOR OF SCIENCE: Mr. MacDonald's interesting article on the heatings in Culebra Cut, in your issue of May 3, No. 905, is paralleled by the spontaneous combustion of bituminous coals, and even of the anthracite culm banks, owing to the oxidization of pyrite. It is a common occurrence, and is the cause of endless trouble in preserving museum specimens of pyrite in fine dissemination during damp weather.

In the case at issue the iron content proceeded from the ferro-magnesian silicates, as Mr. MacDonald has stated; but from ordinary surface oxidation, as is always the case in regions containing the black bisilicates, and as shown by the rustiness of springs and streams. The sulphur content is also generally present in lagoons as more or less dilute sulphuric acid. The presence of carbonaceous material points to a lagoon formation at Culebra Cut.

The function of iron is to be a carrier of oxygen from the air to the precipitated organic débris, changing from hydrated sesquioxide to protoxide: picked up by the above acid: again breaking up as hydrated sesquioxide, and continuing its endless rounds unless it happens to be included and imprisoned under a mass

of vegetation; when the round is stopped, the sesquioxide and the solution of sulphate in which all the ingredients are bathed are robbed of the oxygen and form pyrite.

The classic laboratory experiments show that organic animal matter acts with greater rapidity and sureness, and the resulting pseudomorphs of sphalerite, chalcopyrite, or pyrite, when a live clam is placed in a saturated solution of a sulphate of the above, are well known. We find them abundantly in nature, in the Trenton rocks as well as in the coal measures.

EDWARD H. WILLIAMS, JR.

THE CROCKER LAND EXPEDITION

TO THE EDITOR OF SCIENCE: The Crocker Land Expedition which was to have gone northward this summer under the leadership of George Borup and D. B. MacMillan, has been postponed to the summer of 1913, on account of the lamentable death of George Borup and the impracticability of finding a substitute for him in the short time remaining before the expedition was to start.

The Honorary Committee, consisting of President Henry Fairfield Osborn, Mr. Chandler Robbins, General Thomas H. Hubbard and Dr. Walter B. James, and the Committee in Charge, comprised of Dr. E. O. Hovey and Mr. H. L. Bridgman, have begun the reorganization of the expedition along such lines as circumstances may necessitate, without changing the main objects of the enterprise, as set forth in the prospectus issued in January 1912.

Colonel Borup and a number of the principal supporters of the expedition have united in the furtherance of the new plans; the expedition will be a memorial to George Borup, the young explorer who was so keenly interested in it and who was the mainspring of the original undertaking.

Mr. MacMillan's connection with the enterprise continues as heretofore, and he is utilizing the intervening time for the purpose of making additional preparation for the scientific work of the expedition.

A considerable part of the supplies and equipment had been prepared. The prepared

material has been put into safe storage for use next year, while the special apparatus is being assembled at the museum. Subscriptions already made are sufficient to insure the starting of the expedition a year hence.

EDMUND OTIS HOVEY,
HERBERT L. BRIDGMAN,
Committee in Charge

UNIVERSITY CONTROL

LETTERS FROM HARVARD UNIVERSITY

I AM on the whole very pleasantly impressed, as you know, with the general constitution that has been worked out at Harvard: a bi-cameral arrangement for the general governing boards; one large academic faculty and several professional faculties for the boards of instruction; comparatively independent divisions and departments, with a considerable range of initiative within their own fields; a president who is, while powerful, still subject to a great many decidedly distinct and potent sorts of checks from alumni and from various boards. This constitution does not seem to me perfect. The president at Harvard has probably still too large a range of discretion. The result is certainly not bad; but is also still subject to further growth. The bi-cameral system (the "overseers" elected by the alumni, able to advise but not to initiate legislation, able also to veto; the "corporation," self-perpetuating and capable of initiating, but always subject to the overseers' veto), seems to me to work well but unevenly, since the overseers have their seasons of too great or too little activity, while the president is probably a little too potent in influencing the corporation legislatively. Nevertheless, I regard the result of the interaction between the "overseers" and the "corporation" as so useful in many crises, and so convenient both in calling out and in holding in check the interests of the alumni, that I can not be convinced of the value of your proposals 1 and 2, if they were regarded as contemplating a constitution intended to take the place of ours. I should say, in place of your proposal (1), that a bi-cameral governing body like ours is preferable to the

arrangement that you prefer. Let the alumni, or in state universities, perhaps some larger constituency of interested persons, elect one governing board—not one of absolute authority, but a representative and influential board, with a veto power large enough to be a significant guard, and an advisory power large enough to keep the university in touch with its public. Let there be another board, of another origin, to act as legal owner of the property. Let this board have a real, but not too potent authority as a manager of affairs. Let these two boards cooperate with mutual criticism. Then you could afford to give your president more power and dignity than you do in number (2). I do not agree that the president should be as shorn of power as you make him. Let him be reasonably limited, but not helpless. "Security, permanence, honor" are all consistent with a reasonable presidential leadership. With the spirit of your proposals (3) and (4) I am, on the whole, in sympathy, although I could not go so far as you do. I am willing, as at Harvard, to submit the appointment of officers of instruction to the veto of general governing boards; and to have those boards, as well as the faculties and other teaching "units," take part in all legislation that concerns general educational policies. A professor should have a solid tenure of office during good behavior, and should also have freedom of teaching. A department, or division, or other such small "unit" should have a large scope of discretion as to its own work. But one must keep in touch with one's alumni and one's public as to all questions of common educational policy; and this is why the legislation by general boards is needed, as well as the relative autonomy of departments and of individual teachers. You insist on the latter. To that insistence I agree; but I want the general boards to aid also in legislation. As to (5), I think that you go too far in expecting the departments or divisions to elect a senate capable of doing all their principal legislation for them. Once more—a frequent interaction with governing boards of the type of our Harvard "overseers"—boards that represent the

alumni, and that can veto rather than initiate, seem to me a useful aid and check. What one wants is to get all the forces expressed in the university life, without arbitrary mutual interference, but with constant and mutual criticism, and without anarchy, although with plentiful individual freedom. On the whole that is what we have at Harvard.

I recognize the danger of your "Scylla of presidential autocracy" and "Charybdis of faculty and trustee [collective] incompetence." But I have seen so much efficiency, of the right kind, result from the lodging of great powers in the hands of a wise and able president that I am unwilling to agree, concerning this officer, that "his salary should not be larger, his position more dignified or his powers greater than those of the professor." Of course the right man for president is hard to find, and of course the wrong man is occasionally chosen. I wish that every man accepting a university presidency might do so with assurance of the opportunity to retire at any time from the office on a respectable pension; this would be a happy way out, for the president and for the university, in many unfortunate cases; but I would not see the powers of a well chosen, well qualified president stinted. On the other hand, I have seen a great president content to lay his most cherished projects before a large faculty and labor year after year to bring this faculty to his own way of thinking, convinced that in this assembly he had, on the whole, the most intelligent and the most fairminded body of men in the world, for his purposes. The deliberative habits of this faculty under the president were most exasperating to those who are fond of swift decisions in educational questions, and by common consent, as matters of general interest pressed upon us, matters of detail and routine were delegated more and more to committees or to special administrative officers. Moreover, departments or divisions, as they grew in size, assumed new functions, somewhat as they should according to your plan. But through all these changes, a faculty remained a fairly coherent body, mem-

bers generally, old and young, feeling that, when certain questions of general policy were up, each man of them was expected to do his duty, though comparatively few, as a rule, took an active part in the debates. Furthermore, the frequent faculty meetings, though they did not by any means make every member know every other member, tended advantageously toward general acquaintance, and individuals who, from temperament or from departmental affiliations, must differ, could at least differ more intelligently than if they had not known each other by sight. The combination which I have described, a masterful but considerate president, strong enough and fair enough to invite frank counsel, with a faculty willing to give this counsel in a broad spirit of loyalty, has existed, I believe, not in one institution alone, but in many. With this combination formal checks and balances of authority are needless; without it they are of little avail. It seems to me the "necessary and sufficient" condition of genuine success for a university dealing with educational problems as they exist in this country. In using the term faculty I mean a body which controls the instruction leading to some degree or degrees, and I am not advocating general meetings of all the various faculties which may exist together under the university name. It is unlikely that any president could feel himself equally a master of the situation in all the various faculties, arts, law, medicine, etc., of a modern full-fledged university; but the advantage of having some one active man to preside at all meetings of these faculties, to watch, and report upon, and in a measure control, the relations of the several faculties to each other, seems great. A "chancellor" for show occasions, "to represent the university at public functions" or even "to obtain endowments," would, I think, be ineffective in comparison. As to the selection of professors, I fear that the plan of having all nominations come from departments might result in that condition of academic inbreeding which is noted in some places. At any rate, the faculty selection of professors appears to have had a tendency toward this condition in cer-

tain institutions. I am sorry to take issue with you on some of your most important propositions, for I agree with much that you maintain, and especially with your declaration that "security, permanence, honor, the slow growth of traditions, are essential to a true university." The proposition that great salaries are needed to induce able men to enter university positions, or that great salaries would bring into university professorships the best men, on the whole, for these places, I hold to be fallacious. Great salaries are not needed to call great lawyers from the gainful practise of the bar to the security and honor and sense of public service which they find on the bench. Every teacher, every "productive scholar," should feel himself to be a servant of the public, of a public wider, it may be, than any judge can serve. He should bear himself, and be honored, accordingly.

The plan which you outline is an interesting one which I should be glad to see tried as an experiment somewhere where I am not. The gravest danger I see in it is the proposition that professors be nominated by the departments. This would almost inevitably have the tendency to cause the promotion of men already in the departments, rather than the securing of the best man available, if he happened not to be there. The method of nomination by a faculty composed of only the full professors, as is the case in Germany, obviates this difficulty, since the full professors are no longer looking for advancement, and an appointment from outside will not put any one ahead of them as would be the case for all other members of the department. I am not at all sure that even this method of selection by a faculty of full professors is superior to the present methods commonly in vogue. Yale, I believe, has such a system, and I do not see that the appointments there have been unusually strong. The main reason why I feel doubt about your scheme is that the averages of our faculties the country over are still so low intellectually. Mediocrity is the almost unbroken rule. No doubt this will improve in time; it has improved greatly during

the last twenty years. At present, however, I feel that we have a better chance to secure men of intellectual alertness in the president's chair than as a composite photograph of a faculty or department. The catch-words of democracy and autocracy do not appeal to my judgment here. Of course I am with you in desiring to see the universities and colleges of the country so administered that the faculty members shall not feel that they are merely employees of the corporation (trustees), but that they have a large share in deciding policies and in the making of minor appointments. I do not believe it is necessary, to secure this end, to abolish practically as you propose the office of president. I doubt whether during the present generation at least a satisfactory substitute for the president can be devised.

The organization proposed under (1), (2), (3) and (5) depends for its success largely on the possibility of finding a man with the requisite qualifications for president, and securing his election. In throwing the responsibility for this choice directly on the faculty it would have a wholesome effect on this body. But whether any man with no more power given him than you propose for the president could become a leader is doubtful. Certainly Mr. Eliot could not have accomplished what he did for Harvard under this plan. But conditions have changed since then, and more could be done with the plan now. Still, are not our faculties too much bound up in the supposed interests of the undergraduate and with the cruder needs of this immature person, to be willing to take any chances when it is a question of higher scholarship? Are we ripe for this plan? I hope we are; but I do not know. The method of making appointments set forth in (4) is, I believe, a wrong one. At the present time there are not enough first-rate men in mathematics in the whole country to supply even the strongest universities, and I presume the situation is similar in other subjects. It is necessary, then, to discover the man who is scientifically strong early, and moreover it is neces-

sary to want to get the man who is scientifically strong. Now the majority of the men whose vote is necessary for a choice under your plan are not themselves scientifically first-rate men, nor do they know a first-rate man when they see him. They are going in any concrete case to impose conditions, each in itself corresponding to a desirable qualification, but all taken together such that the one (or possibly two) otherwise available first-rate men are ruled out. The result will be the choice of an eminently respectable member of society, who as he grows older will add so much more dead wood to the department and in his turn make the choice of a scientifically strong man difficult or impossible. If really strong appointments are to be made, the choice must rest ultimately with one or two men, as the president and the head of the department; and even two is sometimes too many. There have been cases at Harvard where Mr. Eliot has appointed professors from outside without the advice or consent of the departments, much to the good of the department in question. It is true that when both president and the head of a department are incompetent, good appointments are impossible. But only an act of God can save such a department.

I am inclined to think that the best form of government is beneficent tyranny, but of course such a person as Marcus Aurelius should always be chosen as tyrant. That there are some individuals more intelligent than the average, there can be no doubt. The point is to choose these as our leaders. Personally, the less I have to do with the details of running the university, the happier I am.

I have never reflected on the matter of college administration and my opinion is therefore of no value, and might readily be reversed by study, argument or reflection. I see no reason as yet for believing in your plan. A system like that of Harvard seems to me to work well.

Your plan of a representative rather than a town-meeting faculty seems to me excellent.

The rest of the plan seems to me no better than the one in use here, which has stood the test of use admirably.

I rather believe in finding the right man and then giving him a good deal of power. I confess the practical workings of democratic systems do not inspire me with confidence. In short, I believe in a centralized form of government for universities. This is more a matter of personal feeling than anything I can back with logic. I am quite ready to admit that such a system may not work well in a great many cases, though I think it is satisfactory here at Harvard. If the government of a university is to be of a democratic type then I have very little to criticize in your circular. I don't think a president and a chancellor would work very well. Why not have the trustees elect a president who would be commander-in-chief and then let there be a vice-president chosen by the senate to represent the academic side on the board of trustees? As to units, twenty seems to me too small a number. Why not have two or three faculties of fifty or more each? General discussion is a good thing. But these are minor points.

I can do no better than state my own experience in two universities, viz., Harvard and Toronto. First, I must say that I do not regard the university professor as such, as a progressive entity. He appears to me on the whole to be much less progressive than the average non-academic man. As a consequence of this feature of his psychology, it is often to the advantage of the institution, with which he happens to be connected and certainly to the advantage of his more progressive colleagues, if he has any, that he should feel the spur of presidential displeasure at times. When I was connected with the University of Toronto, there were many things which badly needed setting right, so much so that the university was investigated by three royal commissions within a decade. The remedy which was finally chosen was the appointment of an autocratic president of the American

type. So far as I am aware the academic machine has worked very well since this change. At Harvard the forces of conservatism, not to say the *vires inertiae*, are quite as strong as they are in any other university I have had experience of, and I happen to know that the academic lives of some of the members of the Harvard staff who may possibly be more progressive or energetic than their immediate colleagues, would scarcely be endurable, but for the fear of the omnipotent president. This is true not only of President Eliot's régime, but also of that of the present incumbent, President Lowell. It appears to me that, on the whole, autocratic powers on the part of a university president are a necessary evil. It does appear, however, that there should be some machinery which, in cases of extreme injustice, might exercise a veto on his acts. I do not think that a president having only a limited tenure would be valuable to the university, nor do I believe that it is very desirable to make his position less dignified than it is at present. A very great desideratum at the present time seems to be a professor's protective association, which among its functions might insure its members against unjust loss of position, and which might also act as the advocate of professorial rights in a general way. University professors at the present time in American universities are too much at the mercy of the administration.

I hardly feel qualified to express an opinion about general university organization that would be worth while. I will outline to you the organization that we have in the Harvard Medical School, because it seems to work satisfactorily under our conditions, and this may be of some help to you. (1) The Medical School has an independent budget made up of the income from funds given definitely to the Medical School, and of fees from students. The Medical School pays its proportionate share of the expenses of the general university, such as the president's salary, etc. (2) The Medical School has its own faculty, which is large, as is the custom with Harvard faculties. This faculty is presided over by the

university president, and bears the same relation to the corporation and to the board of overseers of the university as do other Harvard faculties. (3) All teachers appointed for more than one year are members of the medical faculty. These teachers are appointed by the corporation with the consent of the overseers on the recommendation of a committee composed of all full professors in the Medical School. (4) There is a dean of the faculty of medicine, a dean of the Medical School and a dean of the Dental School. The dean of the faculty of medicine is responsible for the preparation of the general business of the faculty. The dean of the schools is responsible for the individual school, its business and its budget. The deans are appointed by the corporation without vote on the part of the full professors. (5) The various departments in the Medical School are organized into six divisions, each division made up of closely allied subjects. Each division elects a chairman, and each member of the component departments who has been connected with the Medical School for more than one year is entitled to a vote. The six chairmen so elected, with the dean of the school, constitute a faculty council, and the faculty council has supervision of matters concerning the curriculum, the extension of the work of the Medical School, etc. To it are referred recommendations from all the divisions and departments for consideration and report to the faculty. In the same way matters brought up in the faculty touching these points are referred to the faculty council for consideration and report. (6) Assistants and instructors reappointed annually are nominated by the professors in the various departments, and their nomination referred to the division acting as a committee on these nominations. If approved by the division, these nominations are sent to the dean, and by him to the corporation for appointment. (7) There is an administrative board of the school appointed by the corporation, which with the dean act upon matters affecting student discipline, to a certain extent financial matters, that is, discussions of appropriations and awards of

scholarships, etc. This seems a rather cumbersome organization, and is probably in part the result of the accretions of time. However, under it pretty nearly every one connected with the Medical School has an opportunity in one place or another to freely express his views on matters concerning the policy of the Medical School, and in some way to record them by vote. At the same time those holding more responsible positions are given an opportunity to have a proportionately larger influence on Medical School matters.

So far as the general outline of your plan is concerned, I should express approval. It may interest you if I tell you something of what we have done here in the Medical School within the last two years as the result of an agitation initiated about seven years ago. Two years ago the present organization was adopted, and it works exceedingly well. The departments of the school—the department means all those which give a separate examination, or which have an assistant or full professor at its head—were organized in divisions of allied subjects. There were six such divisions, lettered A, B, C, D, E and F. Division A includes the departments of anatomy, comparative anatomy and the Warren Museum. Division B includes physiology, comparative physiology, biological chemistry, materia medica and therapeutics. Division C includes pathology, comparative pathology, bacteriology, preventive medicine and hygiene, neuropathology. Division D includes theory and practise, clinical medicine and surgery, psychiatry, pediatrics. Division E includes surgery, orthopedic surgery, obstetrics, gynecology. Division F, dermatology, syphilis, ophthalmology, otology, laryngology. Each division consists of all members of the constituent departments. Those entitled to a vote in the division are members of the faculty, instructors and assistants who have served three years or more. Each division elects its own chairman and a secretary, and matters of interest to any member of the division are brought up for discussion at meetings held for the purpose. The chairmen are

elected for terms of three years, and are not eligible for immediate reelection. The president of the university, the chairmen of the divisions and the dean of the school make up what is called the faculty council. This council considers all questions arising in regard to courses of study or extension of medical study, the general development of the medical school and the creation of new departments, and reports on the same to the faculty of medicine. Questions on such topics may originate in a division and be brought before the council for consideration, or they may originate in the council; but in such case, no matter directly concerning a division or a department shall be referred to the faculty for action until it has previously been referred to a division for discussion and recommendation to the council. Of course there are other details, but I will not make this letter too long by putting them before you. The general plan has now been working for more than two years, and seems to be meeting with entire approbation. Certainly the results are good in that they have brought together men and interests that before were drifting widely apart. It may interest you to know that this scheme is being discussed with a view to its adoption in at least two large medical schools. The essential point in which it differs from the organization of, say, the Johns Hopkins Medical School, is that it increases the dignity of the professor and does not compel a young man who has secured such rank to remain under the control and tutelage of an older professor or else change his university. The fundamental objection to the Carnegie report on medical education has always seemed to me to be the assumption that the Johns Hopkins organization is the best. In the case of that university it undoubtedly worked well, because they were fortunate in securing strong men in the beginning; but certainly the present indications are that they must either reorganize and give some of their juniors independence or else lose them.

It seems to me that the general plan outlined is excellent in so far as it gives a hand

in the control of a university to those who are most intimately interested in its welfare; namely, its alumni, its faculty and the section of the community at large which it serves. I think it is also excellent, in so far as it seeks to increase the dignity and respect in which a university chair should be held by all persons. The weakest part of the scheme, as it seems to me, lies in the direction for securing new professorial appointments. It goes without saying that each department of a university contains among its teachers expert judges of the intellectual standing of men outside the university, prominent in various lines of scholarship and achievement. In so far as the faculty members are judges of the standing of outside men, their judgments are of great value, when the question of appointing a new man to an assistant professorship or a full professorship comes uppermost. On the other hand, I think that a faculty may often err in its judgments as to the type of intellectual work that should be encouraged in a university. I think that in some cases experience has shown that faculties invested with the power of appointing new professors, subject to the approval of trustees, have erred grievously in policy, by appointing men too narrowly along certain intellectual lines. For example, I can readily imagine that at some particular university, some particular subject may be taught by the faculty members in its department, who may be staunch supporters of some particular doctrine or line of work. The men in that department are naturally and properly enthusiastic and earnest in their desire to see their favorite line of intellectual work extended. If they are empowered to appoint new faculty members, they are likely, with the best and worthiest of motives, to appoint new men whose views and work lie parallel to their own. The consequence of continuing such elective policy, might, in the course of years, unbalance a university seriously, developing its activities too extensively in some particular lines, to the neglect of other lines equally important. For the above reasons I consider that while the faculty of a university should have some hand in appoint-

ing new members, the president or some equivalent power should be able to prevent the university becoming too one-sided. It should lie in the hands of the president, or equivalent power, to introduce such new men into the faculty as may permit of the university work expanding harmoniously and uniformly. Of course, the appointing power in the hands of a president tends to give large influence to an individual. To counterbalance that tendency, along the lines of your plan, it seems to me that it should lie out of the power of the president to dismiss faculty members except for flagrant cause. Faculty resignations should only be exacted by faculty action. To sum up, I should like to see your scheme amended by giving appointing power, under certain restrictions, to college presidents, but giving dismissing power exclusively to faculties.

The plan you propose has many advantages. In the case of a department devoted to research it is very important that the officers concerned, who are familiar with the subject, should have almost complete control of the administration, especially as regards the appointment of the staff and the plans of work. It is a misfortune when such a department is controlled by a body of men who have no technical knowledge of the work undertaken, or, by personal inspection, familiarity with the investigations actually in progress. It is particularly unfortunate when such a body is more interested in another department of the university and is likely to take action for the benefit of the latter at the expense of the former. The case is like that of the stockholders of a small railway controlled by a larger railway system. Their interests are likely to be sacrificed for the benefit of some portion of the system in which the directors have greater interests. As regards the details of your plan, I think that you go too far in reducing the powers of the president. Every university should have one man of very high grade who would devote his entire time to the work. He must be a man of affairs and capable of keeping the work of the university

before the influential portion of the public. I do not believe in the English system of a non-resident chancellor who is simply a figure-head. If the various departments were represented on the governing board, and had the right of nomination as proposed in your (4), the powers of the president would be sufficiently reduced. With these modifications your plan seems to me a good one.

(1) I do not see why members of the corporation should pay annual dues. It seems to me likely that the revenue would be smaller under this system than under the present one in which many men elected to university offices voluntarily give much time and money to worthy objects which they foster. I also think it advisable to keep in all forms of government some degree of subordination and that the best interests of all the professors of an institution are best guarded by having the allotment of funds in the hands of men who are unhampered by personal interest in obtaining an allotment as must be the case where a professor serves as a member of the corporation or body making allotments. The tendency would, I fear, be to work to the advantage of certain professors and departments and against a fair deal for other professors and departments. (2) I think the election of a president by the faculty might be an improvement on the present system. The matter of the salary of the president should be adjusted to circumstances. It is to be presumed that the president has unusual expenses by reason of his office, which unless allowed for, might result in only wealthy men being able to take the position. It seems to me the president should have powers greater than the professor, but perhaps only those which pertain to the chairman of a meeting acting in accordance with parliamentary rules. I would grant him veto power in regard to financial measures. (3) Agreed to, except that a department or division may be able to conduct its affairs wisely when the number of members is less than the minimum of ten prescribed by the "psychological constant." (4) Agreed to. (5) Agreed to. My chief objection to a change from the present system of placing the

control of measures involving expenditure in the hands of non-faculty members of the university lies in the innate division of professors into two groups, those with dominant administrative powers and secondary intellectual accomplishment in their professed field of work, and those with dominant studious habits and without aggressive worldly mindedness such as characterizes the administrator busy with the affairs of his fellows. In the proposed plan it seems to me that the chances are that certain groups of men would more than now develop on-sidedness in the policies of a faculty, and that academic politics would receive an additional impulse. But I may be mistaken in this suspicion. The right of the individual professor to vote for representatives should safeguard him in this matter and on the face of it the plan seems to give fair play.

Naturally I do not wholly agree with the proposed plan. I think it is fair to say, however, that I am wholly in sympathy with the spirit of the plan and should agree that our present autocratic government may profitably be modified in the directions which you mention. I suspect that many modifications of the plan would be suggested in connection with any attempt to put it in operation. As I understand your proposition, the chief problem is one of the rôle of the president, and in this I should heartily agree with you that scholarship and research, at least, are likely to be far safer and much more advantageously promoted under the type of administration which exists in European universities than under our own. A wise autocrat may do much to foster the life of a university, but ideal men for such positions are so rare that it seems little less than absurd for our American institutions to continue their present form of administration. I most heartily approve of division organization. With certain slight modifications we might have at Harvard a very efficient organization of this sort, but of course at present all such division units are subordinate in a great variety of ways to the president. One of the most urgent needs in

our institutions, it seems to me, is a good method of choosing professors. This, I think, is wisely provided for in your plan. On the whole, I should favor experiments in the directions which you have indicated and should confidently expect that our university government might be very markedly improved. I feel that we need to take account both of American conditions and of the forms of government which have been thoroughly tested, especially in England and in Germany.

I am in sympathy with much you state in this article and fully in accord with many of your views. The question is complex, especially as between state universities and "private" universities.

I believe it would be impossible to foretell what would be the outcome of such a scheme for university organization as you propose, if applied to our American universities. The present situation needs a remedy and your scheme has so many good points that I would favor a conservative trial of it. I am sure that the last sentence on flexibility and anarchy is what we should all strive for.

I agree with most of your suggestions. In my opinion it is practically impossible for the president of a university intelligently to preside over all the different faculties of the university.

The plan of university control outlined in your enclosure appeals to me as admirable in striving to develop a more equable division of effective powers between faculty and president than obtains in most universities at present.

I am entirely in sympathy with your effort toward the administrative improvement of our universities. Professors ought not to be employees but members of the firm.

I sympathize heartily with the views in regard to university control which you propose, but do not feel competent to discuss the entire subject, especially paragraphs (1) and (2). I may say, however, that I have always felt that a small self-perpetuating corporation,

such as that at Harvard, without age limit for its "fellows," although all members of the university are considered incapacitated at sixty-six or thereabouts, is inherently wrong and altogether autocratic. The corporation should be selected by the alumni, by the general body of instructors, or better perhaps by both, and I doubt much if the appointment should be for life.

I am quite in accord with the scheme proposed and raise a question only concerning one point which is included in (4). While in thorough sympathy with the democratic mode of control, I doubt its efficiency. In such departments as I have been connected with, the lower positions are filled more or less temporarily by men who expect to pass on to other higher positions. They have not the responsibility for the department, as is the case with the professor, and as far as my experience has been, they lack interest in the matter of appointments and policy. Furthermore, they are not acquainted with conditions and men to the extent that the head of the department must be in order to make his department a success. In fact, I believe that the head of the department must be "czar" or "boss," so to speak, and those under him must be responsible to him in order to make such a unit a success. In fact, the executive work of a department in my opinion, must be attended to by its head or a person representing him. On the other hand, I believe that it is important that all matters pertaining to the department should be discussed freely by all concerned, and of course in regard to scientific matters there should be the utmost freedom. We have an organization with the unit similar to that outlined in your plan, and it strikes me that there is apathy and a general lack of interest among the younger men.

I heartily approve the general principles of your plan of university control. A plan which secures a separation of the financial and the educational administration is, in so far, a vast improvement over the prevailing plans which ordinarily assume that one gov-

erning body may be expert both in business affairs and in educational matters. I favor, too, the more democratic control secured by your plan. I fear, however, that the corporation provided for in (1) of your plan might easily be too large and too freely constituted to be efficient. I should consider it highly unsafe to let the corporation include any "members of the community" who might be pleased to "ally themselves with it" and "pay annual dues." There should be some fairly rigid qualifications for membership designed to exclude all who are not willing to give much of their time and energy to the upbuilding of the university. I see no important function in the office of a chancellor. Why should not the president best "represent the university in its relations to the community," for the university is essentially an educational institution—not a business institution? The further details of your plan, as set forth in (2)–(5), I favor without important exception. The plan of electing professors seems unnecessarily complicated perhaps. Here at Harvard the small division or department enjoys a high degree of autonomy, especially in matters of educational nature, much as your plan proposes. I trust that your agitation of this matter may serve to direct the evolution of our universities along more desirable lines.

In regard to your interesting scheme for university control, paragraph (1) I agree with (with the possible exception of the "members of the community who ally themselves with it"). Would not the alumni of the established university be enough representation? I also agree with paragraph (2). The office should be yearly, or for not more than two years, regarded as a position of dignity, and the election come from the faculties. He should be paid during this time more than a professor, because his work will be greater, more bothersome; he will have to attend functions and dinners and should be compensated for this, particularly for the dinners. In paragraph (3) the unit of organization should be the different faculties. I am not sure about the representation in this, but I think that the

representatives should be the heads of the various departments, the men who are really responsible for the character of the work in each department. There is a difficulty here with regard to the very large departments, such as history, literature or chemistry in a university. It might be difficult here to single out the one responsible man. The other plan would be by the election of representatives by the departments of the faculties. This would probably be necessary in the philosophical faculty. The maximum of representatives for each faculty should not be more than twenty. In paragraph (4) I agree fully with regard to the election of the dean and the nomination of professors. The board of advisers I also think is an available feature. One of the great difficulties which I see in university management is that of the removal or non-continuance of inefficient men holding minor positions. Of course, such minor positions, including assistant professors, should be for a term of years and at the end of this term the position should be regarded as vacant and be filled by the best man available. It is much easier to say this than to do it. Certainly in our medical schools and in the hospitals, if a man gets into a minor position he is pretty sure to go on to continual advancement irrespective of the character of his work unless this has been very bad indeed. Nominations by a committee will not obviate this trouble because the committee will not seriously consider this.

The American college president is certainly an anomaly in education; and the wonder is that the system involving him works on the whole so well. Certainly university faculties do not seem well qualified to manage universities; and state or national educational boards are to be dreaded—Heaven save us! Does not the existence of the present system show that faculties are unbusinesslike and are willing to have some one manage for them? The present method presents a strong contrast to that of the directors of a mill or manufacturing company—where the matters germane to the industry are discussed by a board of

directors with a president who is the executive officer. Imagine the feelings of the directors if the president should go to another body, on which the directors have no representative, and state the opinions of the directors as he understands them, or as he desires them to be understood. This is the condition in most of our universities. The faculties should shape the educational reforms of the universities—in a council consisting of not more than twenty men—heads of great departments. The president should carry the votes of such a council to the business and legal councils of the university to ascertain if there are practical objections to the plans of such an academic council. Why should one man assume to shape the educational future of a university?

It seems to me that the cooperation of all faculty members above and including the rank of instructor, should be desired, but how to get this is not clear to me. If the appreciative sympathy of all the faculty is not had, the control surely will go to the "old guard" and there it will remain, not permitting the careful and at the same time progressive policies essential to the health of the university, as a whole, or it will be taken over by some clique, which would be equally undesirable. Perhaps the end could be best attained by the adoption of a near-republican form of control, by which as much authority as feasible could be delegated, but in which all faculty members including instructors should have the right to vote and should be eligible for service on appropriate committees. The chief executive officer should be elected by this voting body, and for a definite term of years. The professors should also be elected by the same body, but for an indefinite period. I have no comment to offer on your suggestions except the single one, that they appear to me to be sound in every particular and worthy of serious consideration. Such universities as have barely escaped shipwreck through the use of wrong policies in control could well follow the plan laid down by you with great profit.

SCIENTIFIC BOOKS

Vergleichende Anatomie des menschlichen Gebisses und der Zähne der Vertebraten.
Von Dr. PAUL DE TERRA. Jena, Fischer.
1911. Pp. v + 451. Mit 200 Textabbildungen.

Thoroughly Germanic is the stamp of this work: in its tireless massing of details, in its bibliography of three thousand titles and no less in its comparative anatomy.

The author, Dr. Paul de Terra, "vorm. Zahnarzt in Zürich," has not been content to regard the human dentition solely as the subject matter of a lucrative profession, but conceives odontology rather as a branch of morphological science. After a section devoted chiefly to the masticatory apparatus of vertebrates and to the development of the mouth cavity and its parts we find an apparently reliable account of the dentition in general, dealing with the macroscopic and microscopic form, the development and calcification of the milk and permanent dentitions, the mechanism of replacement, the reduction and degeneration of teeth, supernumerary teeth, chemical composition of the dental elements and the like.

The author is of the opinion that odontology is still very largely an empirical science with no great number of well-founded doctrines. He says it is difficult, in view of the multitude of controversial matters, to write a consistent text-book of odontology. He has, therefore, striven to state all sides of the controversial questions with great impartiality. This is perhaps the reason why matters relating to evolutionary origins are left in such great uncertainty and why the now well-discredited and thoroughly archaic hypothesis that the molars of mammals arose through the concrescence of single peg-like teeth is treated with so much respect.

The "theory of trituberculy" is very briefly expounded, but without help from Osborn's later researches, especially "The Evolution of the Mammalian Molar Teeth," 8vo, 1908, which the author does not quote even in his bibliography. It is to be hoped that some day writers of text-books on zoology and odontol-

ogy will become aware that the strong and well-founded part of the theory of trituberculy is *not* the view that the tritubercular molar arose from the triconodont and protodont types through "migration of the cusps"—a view that rests upon the slenderest of analogical evidence.

Another desideratum is the final rejection of one of the early trituberculy diagrams (reproduced on page 62 of the work under consideration) which has unfortunately gained a wide currency in text-books. This diagram, which purports to show the spatial relations of the cusps of the upper and lower molars when in contact, is thoroughly misleading, because no teeth known fit together in the way there represented. In every tritubercular-tuberculo-sectorial dentition, as well as in derived types, the protocone of each upper molar fits squarely into the talonid and behind the trigonid of the corresponding lower molar; as the hypocone is developed it reaches into the valley of the trigonid of the next following lower molar. Primitive Marsupials, Rodents, Insectivores, Carnivores, Primates, "Ungulates" of all orders, all conform to this rule, which furnishes a complete clue to the spatial relations of all parts of the upper and lower molars when in contact. As the reviewer has elsewhere shown, this fact has an important bearing on the derivation of the tritubercular dentition. The alternating relationship of the parts of the upper and lower molars was probably established very early in the history of the Mammalia and is indeed clearly foreshadowed in some of the extinct mammal-like reptiles of South Africa (*e. g.*, *Diademodon*, *Sesamodon*).

It is unfortunate that the author with all his diligence should have made so little effective use of contemporary vertebrate paleontology which might have furnished him with a well-organized method of interpreting at least in part his great compilation of undigested facts about the dentition of fishes, amphibians, reptiles, birds and mammals, a subject covering about 200 pages of the present work. If one wishes to know how many teeth

there are in the jaws and of what kind they are, in recent forms and in a good many fossil forms, he will most likely find here a careful statement of the facts, which is after all the professed purpose of the book. Certain it is, however, that such odontographical information is merely the beginning and not the end of odontology, conceived as a division of comparative anatomy.

WILLIAM K. GREGORY

Modern Industrial Chemistry. From the German of H. BLÜCHER. Translation by J. P. MILLINGTON, M.A. (Cantab.), B.Sc. (Wales), formerly Scholar of Christ's College, Cambridge. The Gresham Publishing Co., 34 and 35 Southampton St., Strand, London. 1911.

According to the publisher's note, this volume is put forward as a standard work, now for the first time issued in an English translation, designed to cover the whole range of subjects with which the chemist and manufacturer are usually concerned. It is not intended as a text-book, but to occupy a position between the text-book and the lexicon. It is arranged in strictly alphabetical order and should therefore be regarded as a dictionary of chemistry.

It is conveniently issued in a single volume of 780 pages. With the exception of the convenience of having a compendium of this sort issued in a single volume, it is difficult to see in what respect this work presents any advantages over the standard dictionaries of chemistry such as those of Thorpe and Watts. It certainly can not be called up-to-date. Many of the leading industrial processes and products are not well handled, especially from the standpoint of American industry. The treatment of the chapter on industrial alcohol, for instance, is not in accordance with the best modern information, and the same may be said of the article on sugar manufacture. Under the descriptions of asphalts, petroleum, tars, etc., many of the statements seem arbitrary and misleading from the standpoint of American technology. The translator has evidently found considerable difficulty in find-

ing synonyms for German technical names and phrases. The properties of both asphalts and tars, as related to their residual products, now so much used for paving purposes, are inadequately treated, and unimportant patented preparations seem to be given too much prominence. Water gas tars, for which considerable uses have been found, are not mentioned in the volume.

Under pigments and oils, we find a very fair but brief description of the various dry colors, mineral and artificial, as well as pigments used in the manufacture of paints. The treatment of the manufacture of white lead is, however, very old, and does not include any mention of the new processes now in use both in America and abroad, such, for instance, as the Rowley or the Picher processes. All of the more common oils and thinners for paints are briefly described, and considerable matter concerning the manufacture of varnishes is included. The newer paint oils which have come into prominence of late years are not mentioned.

Metallurgical processes are described only briefly, and for the most part the descriptions do not adhere to the usual or best practise common in American metallurgy.

Perhaps the most useful feature in the volume is comprised in the digest of foreign and local patents, which touch upon a number of the principal subjects cited and which afford considerable data for reference purposes. The book is well printed and presents an attractive appearance. It will undoubtedly be a valuable addition to a reference library for the chemist or manufacturer, but should not be accepted as authoritative or up-to-date in all the numerous subjects which are covered.

ALLERTON S. CUSHMAN

SCIENTIFIC JOURNALS AND ARTICLES

THE April number (volume 13, number 2) of the *Transactions of the American Mathematical Society* contains the following papers:

G. A. Bliss: "A generalization of Weierstrass's preparation theorem for a power series in several variables."

SPECIAL ARTICLES

TERTIARY DEPOSITS OF EASTERN MEXICO

OUR investigations during the past year on the eastern coast of Mexico have brought out very important facts in connection with the historical geology of the Gulf Coast.

As stated in this journal a year ago,¹ deposits which are lithologically and faunally the same as those referred to the Eocene in the Texas Coastal Plain were traced southward through northeastern Mexico to the Conchos or Presas river. Fossils characteristic of sub-stages of the Texas Claiborne were found on this river, and beyond it the sediments were traced southward to a point a few miles north of Abasola, where they passed from sight beneath the overlap of the San Fernando Oligocene. The materials of the Eocene throughout this region are clays and sands in all respects similar to those of the Texas area and the fossils are species practically identical with those of that region.

The materials of the Oligocene are yellow clays and sands with thin beds of impure limestone, carrying an abundant fauna. These beds are not represented at all in the Texas area between the Brazos and Rio Grande. If they were ever present they have been eroded or concealed by the overlap of later beds.

From the point north of Abasola, where the San Fernando is found resting upon the Papagallo shales of the Cretaceous, this contact continues southward along the eastern border of the valley of the Soto la Marina river to the town of the same name; then it parallels the eastern flank of the Tamaulipas range, drawing gradually nearer the Gulf shore until, in the vicinity of Tordo bay, the Cretaceous is found within 8 miles of the coast.

¹ SCIENCE, Vol. XXXIII., No. 841, pp. 232-234.

No deposits in any way similar to those of the Eocene of this northeastern region have so far been observed south of Abasola, which is 120 miles north of Tampico. The last characteristic Gulf Coast Eocene fossils were found on the Presas river 160 miles north of Tampico.

In the region to the south and west of Tampico an entirely different condition exists. The Papagallos shale continues along the western border of the lowland and also occurs as inliers in the later formations. It is a compact blue shale, more or less calcareous, and up to the present we have found no fossils in it.

It is succeeded by a shale so similar in color and general structure as to make a separation extremely difficult, unless one is fortunate enough to find the fossils which occur here and there in it. One such locality is that on the Buenavista River near Alazan, some 25 miles northwest of Tuxpam and 75 miles south of Tampico. A collection of fossils made at this point by Professor Cummins shows a fauna consisting principally of small gasteropods with a few bivalves, many of which are very similar to, and some identical with, those of the Tejon beds of the Pacific coast. More detailed examinations will doubtless result in recognizing these beds at many other localities, since they unquestionably underlie a large area. They may even extend northward through the valley in which the Tampico and Monterey railroad runs, since we found similar fossils in a well at Topila at a depth of 1,810 feet. From this locality we have the following forms as determined by Mr. G. C. Gester:

1. *Dentalium stramineum* Gabb.
2. *Surcula monolifera*.
3. *Turris* n. sp. (near but not *Claytonensis*).
4. *Olivella* near-*mathewsonii*.
5. *Corbula* (species not determined but identical with a specimen from Marysville Buttes Tejon).
6. *Tritonium* (*Murex*) n. sp. (identical with material from Marysville Buttes Tejon).
7. *Conus remondii*.

8. *Neverita secta* or *Lunatia hornii* (Gabb).
9. *Neverita secta* var.
10. *Tritonium* sp. (identical with specimen from Marysville Buttes).
11. *Turris* n. sp.
12. *Turritella*.
13. *Cerithium*.
14. *Eulima*?
15. *Acteon*?

Out of the fifteen species here enumerated, five are identical with Tejon species and six others are very closely related to them.

Not only are the fossils of this area of Pacific coast types but the sediments are similar to those of that area and entirely different from those of the Texas region.

These Alazan shales are overlain directly by the yellow clays of the San Fernando, which are well exposed both west of the Buenavista River near Alazan and eastward between Solis and Meson. Large quantities of fossils are found, including *Orbitoides papyracea*, echinoderms, pectens and many species of this as yet unstudied fauna. These yellow clays and sands are the surface material over a large portion of the coast country between Tuxpam and Tampico and its fossils were found at a number of places in this area. It is succeeded by beds of similar composition but later age, which are found only in a narrow belt along the coast itself.

It appears that from the beginning of the Oligocene to the Pliocene there was comparatively little change in the character of the sediments, yellow clays and sands making up the bulk of the deposits. The difference of age is, however, marked by change in faunas and the San Fernando is succeeded by the Tuxpam Miocene, which we found near La Loma.

The time equivalency of the Tejon and Claiborne being probable, we find here apparently contemporaneous deposition of the Atlantic and Pacific types of middle Eocene along what is now the same Gulf coast within a comparatively short distance of each other. While we have not yet had time to study the Tamaulipas range with this idea in view, it appears probable that it may represent a part

of the old barrier between the two basins in which this deposition was carried on.

E. T. DUMBLE

SOCIETIES AND ACADEMIES

THE ANTHROPOLOGICAL SOCIETY OF WASHINGTON

THE 461st regular and 33d annual meeting of the society was held on April 30, at 8 P.M., in the new National Museum, with the president, Mr. F. W. Hodge, in the chair. The following officers were elected:

President—Mr. G. R. Stetson.

Vice-president—Mr. Francis LaFlesche.

Secretary—Mr. William H. Babcock.

Treasurer—Mr. J. N. B. Hewitt.

Additional Members of the Board of Managers—Messrs. G. C. Maynard, Felix Neumann, E. T. Williams, Drs. E. L. Morgan and John R. Swanton.

The following amendments to the by-laws were adopted:

Art. I., Sec. 1, to read: "... Its members shall be classed as Active, Life, Associate, Corresponding and Honorary."

Art. I., Sec. 2, for the words "This sum . . . January" the following to be substituted: "Members elected at any time during the first half of the calendar year shall pay the full amount of their annual dues; those elected during the last half of the year shall pay one half the regular annual dues."

Art. I., Sec. 3, to read: "Associate Members are those who, after having been elected, shall have paid the annual fee. The annual dues for Associate Members shall be Two (\$2.00) Dollars for each calendar year, payable in January. This sum entitles them to all rights and privileges of the Society with the exception of the *American Anthropologist*."

Old sections, 3, 4, 5, 6, 7, to read 4, 5, 6, 7, 8.

Art. I., Sec. 5 (formerly Sec. 4), "Proceedings" to be substituted for "Transactions"; "or associate" to be inserted after "active"; "those classes" to be substituted for "that class."

Art. I., Sec. 6 (formerly Sec. 5), for "Transactions," read "Proceedings."

Art. II., Sec. 4, for "quarterly" read "annual"; for "transactions" read "proceedings."

Art. III., Sec. 1, for "alternate Tuesdays" read "third Tuesdays of each month."

Art. III., Sec. 3, after the words "Board of Managers" insert "the President."

Art. III., Sec. 4, insert after "President," "or at the recommendations of three members of the Board."

Art. VI., Sec. 1, to read: "These by-laws may be amended by a three-fourths vote of the Active, Associate and Life Members present at any officially appointed meeting of the Society, provided notice of the proposed amendment shall have been given, in writing, at a meeting held not less than sixty days previously."

TRUMAN MICHELSON,
Retiring Secretary

THE PHILOSOPHICAL SOCIETY OF THE UNIVERSITY OF VIRGINIA

AT the regular monthly meeting of the Scientific Section of the Philosophical Society, held on April 15, 1912, Professor W. H. Echols presented a paper "On the Flow of Water in Artificial Channels, Clean Pipes." The paper may be summarized briefly as follows:

The paper continued the investigations presented two years previous, by proceeding to another degree of precision with wider range of application. The result gives for Chezy's coefficient of resistance m in the expression for loss of head in clean pipes

$$h = m \frac{L}{r} \frac{V^2}{2g},$$

the value

$$m = \frac{.0094 + \frac{.00003}{\sqrt{r}}}{1 + \frac{.07V}{1 + (.015 + \frac{.002}{r})V} + \frac{.6r}{r + .1}}$$

r being the mean hydraulic radius and V the velocity expressed in feet and seconds. This value of m applies to the whole class of clean pipes of easy curvature, of glass, brass, tin, lead, zinc, cast and wrought iron coated, riveted iron coated with asphalt. For straight new asphalt coated cast-iron pipes the velocities from the formula should be increased five per cent. and for wooden stave pipes ten per cent. Four hundred experiments were tabulated in the paper with diameters from one tenth of an inch to eight feet and velocities ranging from two tenths to fifty feet. Three graphical plates accompanied the paper drawn to large scale, giving corresponding values of the coefficients m and c and the relations of V , r and s the hydraulic slope. The paper will be published in the *Transactions* of the society, Bulletin No. 10, Scientific Series.

SOME CURRENT CONCEPTIONS OF THE GERM PLASM¹

It is a commonplace of observation that the first decade of the present century has been, so far as the study of heredity and the germ plasm is concerned, a period of observation and experimentation, rather than of theorizing. The speculations as to a physical basis of heredity and its ultimate structure, which began with Naegeli's conception of the idioplasm and micellæ and culminated in Weismann's elaborate system of ultra-microscopic bearers and determiners of heredity and development, have given place to a renewed activity of observation on the structure and functions of the cell in reproduction and especially to experimentation in hybridizing and all forms of plant and animal breeding. We need not go so far as to say that evolution was on its death bed before the Mendelian revival. The study of the ultimate structure and processes of the plant cell has gone on from Von Mohl's time at least without much regard to such highly speculative disciplines as natural selection, Neo-Lamarckianism, neo-vitalism, etc.; still there can be no question that with the rediscovery of Mendelism and the possibility of bringing a great mass of both breeding and cytological data, as to unit characters, gametic purity, segregation and germinal variation and the behavior of the chromosomes in nuclear division and fusion, synapsis and reduction, into one harmonious theory of development, a great impetus has been given to the study of the funda-

¹MSB. intended for publication and books, etc., intended for review should be sent to the Editor of SCIENCE, Garrison-on-Hudson, N. Y.

¹Address of the vice-president and chairman of Section G, Botany, American Association for the Advancement of Science, December, 1911.

mental problems of cell behavior and heredity.

The relative share in this stimulus to renewed and hopeful study of the facts which is to be assigned to the older theories of the germ plasm and to the new observations of mutation, dominance, segregation, synapsis, etc., is a question which may be left to the historian of biological science in the future to determine. There can be no question that De Vries's theory of pangenesis has guided in large degree his experimental studies in mutation.

It will certainly be of interest to attempt to discover how the new observations are related to the older theories of the germ plasm and especially to try to learn how the numerous experimenters and breeders who are putting forth such a flood of data on hybridization, pure-line breeding, bud variation, graft hybrids, etc., find it necessary to modify or discard and replace the terms and conceptions of the older theories in order to give an intelligible account of their observations.

The theories of Naegeli, Darwin, Weismann and De Vries can all be characterized as Datto and others have made clear, as corpuscular theories of heredity and organization more or less frankly based on an assumed analogy between the ultimate constitution of matter as given in the atomic theory and the grosser mechanical organization of living plants and animals. The fate of this assumption in the hands of experimental breeders and students of the cell is certainly a matter of great interest.

We may first note that the outcome of all this activity of research, both in cytology and breeding, has made it increasingly certain that we do have in the permanent structural constituents of the nucleus a real physical basis of heredity. The evidence available ten years and more ago,

that the chromosomes transmit the hereditary characters of the adult organism in so far as they are directly transmitted, which is based on the permanence of the chromosomes through successive generations, due to their method of reproduction by equational division, their constancy in size, number, shape and position in the germ cells, however the latter may differ in shape, motility, cytoplasmic mass, etc., has been continually strengthened as the result of a more careful analysis and interpretation of results.

The attack on the specific character of the chromosomes and their reproduction by splitting, which has been made in the contention repeatedly appearing from both botanists and zoologists, that nuclei may divide by so-called direct division, that is, simple constriction, and still continue capable of perpetuating the species, has in every case on more careful study been found to be due to faulty interpretation or inadequate methods of observation. Only a passing reference to the exploded notions of Pfeffer as to *Spirogyra* and Child as to certain flat worms is necessary in this connection. Cases of apparent preponderance of the female, such as the echinoderm hybrids, in which the enucleated egg cytoplasm determines the type of cleavage and early embryonic development, are always those in which the egg has become a highly specialized cell by reason of the accumulation of yolk stuffs, etc. That a cell so enlarged should have also developed what has been called a promorphology is natural enough. That this pre-conjugation organization is that of the species to which the egg belongs is inevitable, but such cases can have no final significance in determining the question of the relative functions of nucleus and cytoplasm in heredity. Perhaps the best recent evidence that elements of the cytoplasm may also

belong specifically to the germ plasm is found in Meves's observation of the so-called chondriosomes which he finds widely distributed in the tissues of the embryo chick and so evenly scattered in the cytoplasm of each cell that they are somewhat equally allotted to the daughter cells in division. That these bodies may be concerned in heredity is however hardly more than an interesting suggestion. That any considerable portion of their material is really derived from the male gamete is certainly not proven. In sexual reproduction they are as yet to be classed with the ordinary cytoplasm. That they are, however, widely distributed cell organs seems probable. Unpublished observations in my own laboratory show that they are present in the embryonic muscle, connective tissue, cartilage and nerve cells of trout embryos with the same appearance and apparently the same relation to the formation of muscle and nerve fibrils, etc., which has been described by Meves for the chick. That similar structures are also present in embryonic tissues of plants seems probable from the recent preliminary announcement and figures of Guilliermond showing their appearance in the embryonic cells of the kernels of the cereal grains thus confirming the still earlier observations of Bigaud and Lewitsky. That they are in reality *anlagen* for the cell plastids needs further proof, of course, but that we have in them an important and widely occurring stage in the differentiation of embryonic cytoplasm into the characteristic organs of specialized cells in both animals and plants is strongly suggested. Their study may be expected to throw further light on the methods by which the material transmitted by the germ cells comes to its expression in the structural features of the adult tissues.

Other minor objections are being urged

repeatedly against the doctrine, but in my opinion it must be taken as one of the best established facts of cytology to-day that there is a specific germ plasm differentiated from the general protoplasm of the cell, and that this specific plasm is at least carried by and continuously present in the stainable materials of the nucleus. From the cytological side, evidence has continually increased that we have in the chromatin of the nucleus a physical basis of heredity in a very specific sense.

When we turn to the interesting question as to how far the laborious and widespread cytological studies of the past decade have gone toward confirming the earlier corpuscular theories as to the ultimate structure of this germ plasm, we are confronted for the most part as yet with negative results. It can be claimed by no one that there is any substantial agreement among students of the cell to-day as to the existence even of any visible organized structure in the chromosomes themselves. Heidenhain is the most effective recent defender of the theory of an ultramicroscopic organization of the cell and nucleus, but his arguments for the existence of a bio-system below the grade of the chromosome represented by chromioles and centrioles has met with no general acceptance. As Haecker affirms, there is no agreement as to any facts of structure in the chromosomes themselves. The existence of the chromioles as specific units has not been confirmed. Errera has made it clear that bodies of the size of the chromomeres could contain only some thousands or less of proteid molecules, according to the chemical evidence, and it is hardly possible that an organization of any significance could be achieved with so few units. It is not impossible that in the chromosomes we have reached the ultimate units in the organization of the cell, themselves not or-

ganized, but purely chemical aggregates. Certain it is that the strands and granules and the spongy, knotted structure shown in the drawings of the chromosomes by the best cytological students of the day agree superficially in some respects at least with the descriptions of the colloid chemists of the structure of two-phased colloidal systems.

On the other hand, our knowledge of the chromosomes as independent continuously perpetuated organs of the cell has been enlarged and confirmed from many sources.

The extreme form of the doctrine that the chromosomes are independent individual organisms, cells within the cells, is probably an exaggeration, but evidence has continually accumulated that the chromosomes are specific and permanent parts of the cell which are formed only by the division of already existent chromosomes and which are nourished and grow after division so as to maintain within certain limits a size and number characteristic for each species. From the cytological standpoint also the argument for the significance of the serial arrangement of the chromosomes in the splitting spirem has lost none of its force.

The importance of the conclusion that each species has its constant number of chromosomes has only been emphasized by the discovery of cases in which such differential qualities within the species as distinctions of sex are found to be accompanied by a corresponding difference in the number of chromosomes in the two sexes. To be sure, such an extreme germinal difference as the presence of an additional chromosome in the female is probably a rare case found so far chiefly among insects. But the fact that in these cases the structural and functional differences between the sexes in the adult form are correlated with specific differences in

chromosome number in the germ cells must be regarded as strong evidence that the chromosomes represent in some fashion the hereditary characters in the germ cells.

It may well be expected that other slight differences in chromosome number which have been observed within the species will be found to have quite as rational and natural an explanation as have the sex chromosomes. Other forms of dimorphism may perhaps be dependent on corresponding variations in chromosome number or size.

In the case of the sex-chromosomes the question as to how the organs and characteristics of the adult can be represented in the germ plasma is raised in a very concrete form. If the presence of an extra chromosome determines the female sex, it must apparently not only represent the specific female sex organs of the adult, but also a series of secondary sexual characters belonging to the other organs and tissues. The difficulties involved in any corpuscular theory of heredity become conspicuous in such a case. That a series of granules representing *anlagen* for all the various characteristics of the female sex should be brought together in a single chromosome, being thus apparently separated from all the other *anlagen* for the organs which show secondary sex characters, and should still be able to determine the development of the individual in all these respects, is scarcely conceivable. The discovery of the sex chromosomes must be regarded as evidence against the corpuscular theories of heredity.

The view that characters that are sex-limited in heredity must also be determined by materials which accompany or are included in the sex chromosomes makes the situation still more difficult, being quite inconsistent with even a serial arrangement of the elements of the germ plasma

such as the cytological facts as to the longitudinal splitting of the chromosomes seem to demand, and shows how inconsistent with the assumption of even the simplest form of determinate arrangement of elements in the germ plasm Mendelian conceptions are. It is obvious that the couplings seen in sex-limited inheritance suggest the connection of the factors representing them with a sex chromosome. That is why such characters are called sex-limited. But to actually imagine such diverse and easily transferred characteristics of color, etc., affecting such widely separated parts of the adult organism as inhering in or connected with a single sex-chromosome is just as obviously opposed to the common interpretation of the serial arrangement of the chromosomes and their parts. Other cases of Mendelian couplings, such as that of long pollen and purple flower color, are just as inconceivable on the basis of a serial corpuscular representation of genes in the chromosomes. To be sure, Bateson is now inclined to give up the conception of gametic coupling, but the idea has been widely taken up and seems fairly well established among Mendelian conceptions. It differs little, of course, from the older ideas of correlation in heredity. The factors in heredity in such cases are certainly more easily conceived as due to the characteristic constitution of the germ plasm, as a whole, than as represented by unit corpuscles.

One of the strongest pieces of cytological evidence that the number of the chromosomes is due to their own specific and individual characters, rather than any mere mechanical necessities in the cell organization, such as Fick assumes in his maneuver hypothesis, is found in the work of the Marchals on aposporous mosses. By regenerating the gametophyte directly from the sporophyte without the

intervention of the reduction division (apospory) they have produced diploid gametophytes. These in turn in fertilization have produced tetraploid sporophytes, and these by regeneration again tetraploid gametophytes. No stronger evidence for the permanence and independence of each chromosome could be produced. An excess of chromosomes can only be gotten rid of by a specific reduction division, that is, by separating them without the splitting of each into two. Some of the diploid gametophytes seemed vigorous, the tetraploid gametophytes were weak, and the physiological limit for the number of chromosomes in one cell was probably reached in them. These cases, along with those in ferns, show that an excess in the amount of the germ plasm doubling or trebling the representation of each hereditary quality need not necessarily affect the morphological characteristics of the organism, and are in strong contrast with such cases as that of *Oenothera lamarckiana* and certain races of bananas, in which a doubling or trebling of the chromosome number is associated with marked structural changes in the plant. When the excess number of chromosomes fails to produce visible effects, the condition is perhaps analogous to that of ordinary latency. The condition of ineffectiveness of the excess chromosomes in these diploid and tetraploid gametophytes of the mosses, so far as their relation to morphogenetic processes is concerned, also seems analogous to that of the chromosomes of the recessive parent in the F_1 generation in cases of Mendelian dominance. Cells containing two complete sets of chromosomes may show complete resemblance to one parent or mixed, mosaic and intermediate resemblance, depending on the degree of prepotency or latency represented by the conflicting sets of chromosomes. Mendelian dominance and re-

cessiveness represent the extremes of prepotency and subordination in the relations of the diploid germ plasm.

Such evidence as this suggests that the germ plasmas are related to each other much as competing races of organisms are. The evidence here may be said to favor the idea of the germ plasm as a mass of independent individual corpuscles competing with each other for their existence. One of the most obvious ways in which Mendelian concepts have influenced the idea of the germ plasm is in the emphasis which the idea of Mendelian dominance gave to the conception of antagonistic relations between its elements. Of any two characters present in the parents, one may dominate the other in the offspring without destroying it. These facts are obviously opposed to a chemical theory of the germ plasm. If the union of the two factors is chemical it should result in some new compound with properties in some degree different from either. As has been pointed out by Friedmann on chemical analogy, the product of the union of two germ plasmas would not necessarily be intermediate in its properties between those of the two combining elements, especially in its form and spatial configuration. The angles of a crystal made of a mixture of two isomorphous salts are not the average of the angles of the two components. Such so-called chemical theories of dominance as assume the existence of regulative enzymes influencing the rate of morphogenetic processes by their relative concentration seem to me to beg the whole question by assuming in the appearance of the regulative enzymes at the critical point the element of organization which they start out to deny.

Not only the facts as to constancy and variation in the number of chromosomes, but also our knowledge of their constant

arrangement and position in the cell nucleus, has been greatly strengthened by the critical study of recent years. The accumulating evidence for the constant position of each chromosome in the resting nucleus as it reappears after the disturbance of nuclear division is most suggestive of mechanical organization in the nucleus as a whole, whether or not there be an ultra-microscopic organization of the chromosomes themselves.

Boveri has shown for *Ascaris* that the long chromosomes of the embryonic nuclei reappear at each cell generation in the same position and determine the configuration of the young resting nuclei. In certain fungi at least there is permanent connection between the chromosomes and centrosomes, thus determining the polar organization of the cell as conceived by Rabl. These conditions give strong evidence for a mechanically organized, rather than a mere chemical cell and nuclear structure.

No more important question confronts the students of the cell to-day than the determination of the relative positions of the paternal and maternal chromosomes in the diploid vegetative cells. Evidence that the serial arrangement found in all sporems is maintained in the resting condition and in the equatorial plate of a species of *Carex* will be presented at this meeting. Strasburger, Overton and others find that the chromosomes are paired throughout vegetative development, the members of the pairs representing respectively maternal and paternal elements. If these results are confirmed and found to be general, we have a further vantage point from which to attack the question as to the method by which the parental germ plasmas are not only transmitted but come to expression in the offspring.

It is fairly well established that homol-

ogous chromosomes are paired in synapsis, and the prophases of the reduction division. The evidence from cases of chromosomes of unequal length in both animals and plants seems convincing on this point. The determination of the relative position of the parental elements in the vegetative cell generations would go far to settle the vexed question of whether this pairing is side by side or end to end. Without going into the evidence on this point, so many times reviewed in recent years, I may express my opinion that it favors the side-by-side conjugation and, further, indicates that the union of the two parental germ plasms is, in many cases at least, a very intimate one, so that in the pachyneme spireme the visible identity of the two parental elements completely disappears. The discovery that this intimate union of the germ plasms comes at the close of the F_1 generation in the preparation of the germ cells for the F_2 generation forms perhaps one of the closest points of contact between the results of cytological study and experimental breeding. The long-known relative constancy of the first hybrid generation contrasted with the breaking up in the succeeding generations has here its counterpart in the relations of the germ plasms in the reproductive cells.

It seems plain to me also that the behavior of the chromosomes in thus uniting so intimately that their visible identity is lost in the pachyneme spireme, is strongly opposed to the conception of universal and absolute gametic purity and unit characters. It is a very obvious suggestion that the elements of the gametes should not be pure after this union. This obvious suggestion from cytology may clear up the behavior of the offspring from many crossings better than the assumption of more unit factors. The behavior of the parental chromosomes in synapsis and the follow-

ing stages is well calculated to provide for just such fluctuating variability as well as a certain degree of stability as the breeder unbiased by Mendelian preconceptions finds. It is quite possible that in some cases pairs of parental characters may separate or interchange without a trace of mutual influence, but the close union found in the synaptic knot and the succeeding spireme certainly seems adapted to provide the opportunity for a vast amount of modification and interaction between the parental germ plasms.

At this stage again we are confronted in very concrete form with the alternatives of a chemical and mechanical organization of the chromosomes and the difficulties involved in the corpuscular theories become very conspicuous. There is no visible provision in synapsis for maintaining any such space relations between the determinants as Weismann's theory requires, and if we consider the case of the more vaguely arranged pangens of De Vries, it is still at least very possible that chemical reactions might occur between these minute proteid masses so intimately associated as they are.

In the phenomena of reduction, on the one hand, and segregation, on the other, the work of the cytologist and experimental breeder finds a most intimate point of contact, and the results of studies on these phenomena from both standpoints must have the most profound and far-reaching effects on our theories of heredity. The facts of synapsis are even more opposed to complexity of organization in the germ plasm than are the facts of nuclear division which have been so much emphasized.

To understand the present point of view of cytologists and breeders more clearly we must briefly examine the current corpuscular conceptions of the germ plasm. Detto's analysis and criticism of these

views seem to me most suggestive. In his attempts to explain the heredity of form, Weismann conceives a so-called heteronomic structural preformation of the adult plant or animal as existing in his determinants and their architectural arrangement in the germ cell from which it arises. The development of the individual is epigenetic in a sense, but the corpuscular *anlagen* determine the outcome of the series of epigenetic changes. The assumption of all those who hold to a representation of the adult organism in the egg seems to be that if development is really to be explained a complicated spatially differentiated organization must be supposed to exist in the fertilized egg. Hertwig, in his doctrine of epigenetic cellular interaction, also assumes a complicated qualitatively differentiated germ plasm, but these heteronomic preformed structures develop and differentiate themselves under the influence of intercellular and environmental interactions.

Weismann's material determinants are to be described as heteronomic, because there certainly is no visible resemblance between their organization and that of the adult body. It is held that the tissues of the adult body are not to be considered as especially preformed, but that they may be represented in the egg not as formed parts, but as particles in which inhere particular qualities and capacities of the protoplasm. These particles are not identical in organization with the adult characteristic which they determine, but they necessitate the development of that particular adult structural quality. It would seem that the important thing here is the quality or potency rather than the particle, and the difficulty is in assuming complex potentialities as inhering in particles of simple structure. Detto has proposed to call certain of these *anlagen* metidentical,

to indicate that they are heteronomic as regards the actual adult characteristics, but identical with the protoplasmic qualities which are assumed to cause them. Regulative *anlagen* are also assumed which, acting catalytically, perhaps, produce their effects in such fashion that basic protoplasms may be worked out into a product of specific type. It is assumed to be conceivable that form may be due to regulative form *anlagen*. Elements of the cytoplasm forming an internal environment for the germ plasm may act as regulating factors of this sort.

Such doctrines of qualitative preformation aim to explain the architectural arrangements of the adult organism, but as Detto points out, we really explain nothing by simply assuming in the egg a so-called metidentical and heteronomic representation of the structure of the adult. Any organization in the egg which will help to explain the complex and adaptive spatial configuration of the adult organs and tissues must be assumed to possess a similar spatial configuration in three dimensions. In a word, we can explain by our *anlage* no greater degree of spatial complexity than we put into it.

A most striking feature in the assumptions of present-day experimenters is their thoroughgoing break with the conceptions of Weismann as to the existence of germinal elements representing tissues or organs of the adult plant, and in definite space relations with each other in the germ plasm. Many of the factors of the Mendelians have no particular space relations in the adult. Tall and dwarf habits are diffuse characters of the plant, as a whole. Hairiness may be on stem, leaves, calyx, part or all of them. Mendelian hereditary units are not leaves, petioles, stamens, etc., but qualities of these organs or still more diffuse qualities of the whole plant. Fixed

space relations between elements of the germ plasm are quite unnecessary in the heredity of such qualities.

With the disappearance of Weismann's conception of definite and complex space relations between the elements of the germ plasm, we perhaps see the last of the old doctrine of formal preformation. And yet it is a curious fact that one of the most important influences which Mendelian studies have exerted on our conceptions of the germ plasm seems to be in the stimulus which they have apparently given to all corpuscular theories of heredity. The doctrine of unit characters is the real gist of Mendelism, and it seems obvious to associate these unit characters of the plant, as a whole, with the theoretically postulated determinants, granules, etc., of the corpuscular theories of heredity.

The relative popularity of De Vries's conception of the *pangens* is due to the emphasis he lays on the conception of units representing diffuse characters of the plant as a whole rather than organisms or tissues. De Vries's *pangens* are assumed in many cases to represent just such qualities and characteristics of color, size, etc., in the plant as are found to show the Mendelian behavior most perfectly. It is certainly a striking fact that Mendel and De Vries independently reached the conception of the importance of such characters in an analysis of heredity. That De Vries should regard them as units is due to the influence of his corpuscular theory of the germ plasm. They are more properly described as diffuse characteristics of the plant or its organs, as wholes, as De Vries has so strongly emphasized in relating them to the origin of his mutants which differ from their parents in general features affecting the whole organism.

It must be remembered also, that while De Vries makes his *pangens* stand for

characteristic features of the plant or its organs as wholes rather than for specific organs or tissues, and rejects Weismann's and Naegeli's conception of a mosaic combination of the units in a germ plasm, yet he is not free from the feeling that a definite spatial relation of the *pangens* in the germ plasm is necessary. The *pangens* must be in smaller and larger groups and these groups so arranged that the members of a group may become active at the same time at least. The arrangement must also be such as to provide for their proper distribution at each cell division. This sounds as if a relatively simple serial arrangement were all that is necessary, but as noted, the coupling of *pangens* representing all the secondary sex and sex-limited characters affecting widely distributed organs of the body, which in many respects are otherwise determined, with a single sex chromosome or group of *pangens*, is not a simple matter. The doctrine of intracellular pangenesis, with its storage of *pangens* in the nucleus and their migration into the cytoplasm, provides for the behavior of the Mendelian factors hardly better than the formal unfolding of the architecturally prearranged corpuscles of Weismann's theory.

That the harmony in underlying assumptions between the Mendelians and the adherents of corpuscular theories of heredity is only apparent seems to me the inevitable conclusion of any careful analysis. A list of the characters associated by De Vries with his *pangens* is itself suggestive of difficulties. The first character he mentions in his intracellular pangenesis is the green color of plants. That this is a characteristic of plants which have a certain unity of behavior in heredity may be true, but to see how it can be represented by a *pangen* granule in the germ plasm so as to appear in just the proper tissues in just the proper degree is not so obvious. Other

pangen characters, such as those for the production of specific alkaloids, oils, tannin, etc., involve the same difficulties, and this is no less true for morphogenetic *pangens* of leaf form, etc. To speak with Klebs, such *pangens* should be potentialities rather than material granules.

The failure of the experimental breeders to characterize more exactly the hypothetical units, genes, etc., in the germ plasm which represent their factors is not all due to a desire for absolute freedom from prejudice in matters of theory, but rather to an inability to identify the behavior of their factors with that of any such units in the germ plasm as the older theories have assumed. Johannsen gives a name to the units of which his germ plasm is composed, the genes, but he defines genes and genotype strictly from the visible behavior of the different characters of the many-celled plant. The genotype is the specific germ plasm, each of the genes represents a unit character. How they are situated or related in the egg is unspecified, though it is suggested they probably have only a chemical constitution.

The Mendelian unit characters are, as noted, most typically generalized qualities of the plant or organ as physiological wholes. They are very diverse in their character and there is little attempt as yet to classify them. We have quantitative characters of weight and measure in fruits, stems, etc., superficial factors of color, which palpably depend on nothing more fundamental than a slight change in the degree of oxidation of a by-product of the protoplasm or a variation in the alkalinity or acidity of the cell sap.

We have factors for annual and biennial habit, as well as the more fundamental factors for form and tissue differentiation which are essential to the every-day existence of the organism. These heterogeneous

factors show couplings, repulsions, etc., without regard to any, at present, explainable relationship between them which would make it possible to associate them with any definite spatial distribution of *anlagen* in the germ cells.

It may be found to be one of the most valuable results of Mendelian experimentation that it has helped to destroy the last vestiges of preformationist ideas which inhered in the prearrangement of the hereditary corpuscles assumed in the theories of Weismann. It is certainly impossible to imagine where a corpuscle should be placed in the egg or what it should do to change a plant from an annual to a biennial, or a crenate to a serrate leaf.

It is sufficiently clear that the results of Mendelian and mutational breeding from the standpoint of the kind of unit factors observed and their behavior in cases of so-called coupling and repulsion are opposed to the doctrine of a spatially organized germ plasm made up of corpuscular units. The doctrine of the fixity of the unit characters and their segregation as pure elements seems still, however, to harmonize well with the conception of *pangens*, perhaps not so definitely related to each other, spatially, in the germ plasm. If there are fixed elements, unit characters, which are transmitted in reproduction, this is certainly strong ground for the assumption of the existence of corresponding corpuscular units in the germ plasm. The experience of experimental breeders with the doctrine of segregation must be examined critically as to the evidence it gives on this point. It is a fundamental assumption of Mendelism that the characteristics of the parents behave in fertilization, whether hybrid or normal, as unit characters, and that hybridization and the phenomena of segregation which follow give the best possible means of recognizing and identifying

them. Still there can be no question that the doctrine of segregation and alternative inheritance no longer has the clear and simple form in which Mendel proposed it. It is equally certain that the changes which have been made were necessary in order to bring the theory into harmony with the vast mass of new facts which breeding on a large scale has brought to light.

These modifications have largely been in the direction of providing for a greater degree of variability in the F_2 and succeeding generations than is provided for by the doctrine of segregation. Pre-Mendelian views held to a general breaking-up and tendency to vary in hybrids after the first generation. It was Mendel's great contribution to apparently discover in this multiplicity of forms a real simplicity in fundamental features. Recent workers have, however, found it increasingly difficult to interpret their results within the limits of the Mendelian formulæ.

One of the first steps in the modification of Mendel's views was to admit greater variation in the first generation. It is generally agreed now that there is no law of dominance, that the first generation may be intermediate, or a mosaic of the parental characters, and the possibility is present that there may even be di- or poly-morphism in the first generation. Practically all the pre-Mendelian conceptions as to the character of the first generation have now been confirmed and generally admitted.

An important step toward the modification of the Mendelian account of segregation in the second and following generations was in the introduction of the presence and absence hypothesis as a substitute for the Mendelian doctrine of pairs of positive visible characters. The presence and absence hypothesis when applied to simple Mendelian pairs of contrasting characters seems perhaps to have a sort of explana-

tory value. To be sure, the case is somewhat as if a geologist should explain a given hill as due to the absence of a mountain, failing to suggest anything as to the forces and conditions concerned in the production of both hills and mountains. There can be no question that Mendel's doctrine of segregation assumed the probable occurrence of alternative inheritance for all homologous differential qualities in the parents of hybrids. It was the task of the breeder to discover such pairs of opposite characters and operate with them. This has been found to be impossible in many cases, and the presence and absence hypothesis is advanced as an expression more nearly in accord with the facts as found in practical breeding work. The facts that have necessitated this change show that not all apparently homologous contrasting characteristics form allelomorphous pairs. When two contrasting flower colors are found not to form an allelomorphous pair, the pairing may sometimes still be discovered by operating with groups of characters in the formation of allelomorphs, such as pigmentation against white or albinism, and here again albinism is by no means always found to be the same thing in heredity.

In other cases the presence and absence hypothesis is introduced as a concession to the fact that the second and following hybrid generations are much more variable than the Mendelian doctrine allowed. On the Mendelian hypothesis of allelomorphous pairs and their segregation, two individuals differing in a single character, such as flower color, could produce but two kinds of gametes and four groups of offspring. On the presence and absence hypothesis we can assume at once four elements, a factor for the presence and absence of each of the two colors. To take the stock illustration: fowls with pea and rose combs when crossed

are found to produce two further new comb types, walnut in the F_1 and single in the F_2 generations. The whole result harmonizes with the assumption that we have here two allelomorphic pairs—rose present and absent and pea present and absent—the absence in each case resulting in single comb.

The real discovery here is that two birds visibly differing in the one feature of comb character do not produce monohybrid offspring, as in the case of the green and yellow peas, but show on breeding that the qualities pea and rose comb belong to separate allelomorphic pairs. This permits of four kinds of gametes and sixteen different combinations in the F_2 generation. That is, the result resembles that of a dihybrid rather than a monohybrid combination.

It is really a case of the assumption of two factors as responsible for a single unit character. And the use of the presence and absence hypothesis perhaps tends to obscure the real facts. Single comb is superficially at least just as positive a character as pea or rose comb. Single comb is found to occur in the absence of either pea or rose comb. If the absence had not happened to have the same result in both cases—if, for example, absence of pea comb had meant no comb, then the cross would have had a still different result. Stated in plain terms, the experiment shows that in applying Mendel's principles to a wider and wider range of experimental material we find it necessary to provide for a much greater degree of variability in our results than was anticipated. The pre-Mendelian dogma of the breaking-up of the F_2 generation is to this degree vindicated.

This adoption of the presence and absence hypothesis and of additional factors is probably an entirely correct method of procedure as far as it goes, and allows

much more fully for the real variability which we find in heredity.

That the increase of diversity with added pairs of differentiating characters in the parents should follow just this Mendelian law is, of course, only necessary on the assumption of fixed unit characters. It is a question whether it is sufficiently obvious that we need just twelve more groups in which to place our phenomena when we pass from the results of crossing parents with one visible difference to those with two visible differences. Perhaps some other number of groups would really classify the results of such a cross just as well as sixteen.

It is to be remembered that the biometrician dealing with symbols can proceed with perfect certainty that his results will be mathematically correct without troubling himself in the least as to whether his series of symbols corresponds to any realities. Handling a series of the combinations of numbers or letters from one to ten is very elementary mathematics, but to hold in mind and be able to visualize from day to day with certainty of a constant result ten related colors and their combinations in a bed of snap-dragons is, as can be shown by appropriate tests, a matter of expert training and considerable uncertainty. When we realize further that unit characters are not conceived as hard and fast categories, but as each having an allowed range of fluctuating variability, we can see that the chances of mistake in estimating the sixty-four classes of offspring which might come from a pair of parents differing in three characters are very great. It is a matter of difficulty for the student of the problem and it is almost impossible for any one who reads of such results to pass any critical judgment on their probable accuracy.

Formally the presence and absence

hypothesis is perhaps consistent with the corpuscular theories of heredity but the necessity of its introduction arising from the variability of the products of hybridization must be regarded as seriously affecting the basal conception of segregation of fixed unit characters.

Perhaps the most important modification of Mendelian theories is in the continuous discovery of further cases in which single visible characteristics as conceived by Mendel or De Vries may be dependent for their realization on from two to several factors, or may arise in more than one way. Nilsson-Ehle tells us that the black color in oats and the red color in certain wheats may each be produced in different ways. Shull finds that two separate genes may be responsible for the common form of capsule in *Capsella bursa-pastoris*. Bateson and Saunders tell us that certain white varieties of peas and stocks when crossed give purple. This is because the colors in question are due to two factors instead of one. These two factors are not members of one allelomorphic pair but must be assumed to be the members of two distinct pairs, each from different parents. Hoariness in stocks is dependent on four factors, two for hoariness and two for flower color, not compounded in one unit but distributed in four allelomorphic pairs. Reversion is the reappearance of a character because of the reunion of the two necessary factors which had become separated.

An extreme of this tendency is found in Tammes's recent paper on heredity in flax in which she has worked with three types and apparently has used all possible precautions as to control, etc. Tammes finds that the results of her study of seed size, petal size, petal color, etc., can only be brought into harmony with Mendelian ratios by assuming that each of these visible characters is dependent on from one

to several factors in the germ plasm. For the length of the seed at least four factors must be assumed. For length and breadth of petal three factors must be assumed in one cross and at least four in others. For flower color three factors were found; for dehiscence of seed pod three or four factors; for hoariness of seed pod alone one factor. Tammes finds in crossing two individuals differing in a single visible character where Mendel would expect to find a monohybrid giving four combinations in the F_2 generation that the results are those which should be expected in the case of a di- or poly-hybrid. In plain terms this merely states that the F_2 generation is, as the older views of hybridization held, vastly more variable than the ordinary Mendelian expectation permits.

It is probable that Tammes and the others who are assuming a multiplicity of factors as necessary to the production of a single visible character are giving the facts as they find them, but the doctrine of fixed unit characters represented by pangens or genes in the germ plasm certainly shows itself inadequate to account for such facts. These results attack the doctrine of the *pangen* at its very foundation. According to De Vries the multiplicity of plant and animal forms is due to the large number of combinations possible with relatively few unit characters. We are now given multiplicity in the germ plasm to account for apparent simplicity in the organism. On Johannsen's view also each factor must be represented by a gene in the germ plasm.

Furthermore, as noted, the unit characters are diffuse characteristics of the plant taken as a whole. Each hereditary factor responsible for this diffuse character may influence many parts of the plant. We have thus a most complex overlapping of functions among the factors, one char-

acter being dependent on several factors and each factor affecting a number of parts and even qualities of the plant.

Even the most thoroughgoing Mendelian must admit that a unit character made up of four fractions or assumed to be dependent for its realization on four factors has lost something of its unity. What the student of the germ plasm wants to know, of course, is the nature of these fractions or the ultimate elements in heredity, whatever they may be. The breeder may perhaps properly, as Baur does, relegate all questions as to the nature of the representation of the hereditary qualities of the many-celled organism in the egg to the future as outside the scope of his immediate experiments. The cytologist dealing directly with the germ plasm in the chromosomes is confronted directly with the question of their ultimate constitution and must attempt to connect any discoverable units in the make-up of the adult in some way with the structure and properties of the germ plasm itself. It is obvious that visible characters which may arise in more than one way or that require the combination of from two to several factors for their production can hardly be represented in the germ plasm by the *pangens*, determinants or other corpuscular units of the older theories. To call a visible character which depends on four hereditary factors for its production a unit character is certainly not conducive to clearness of thought. To attempt to find fixed units in the maze of fluctuating colors, forms and physiological processes of multicellular plants looked upon as wholes is perhaps a hopeless task. Much more is it inconceivable that such diffuse fluctuating characteristics are represented by specific corpuscles in the germ plasm.

We have noted that Mendelian breeding, emphasizing as it does the existence of

characteristics belonging to the organism as a whole and their couplings and repulsions in inheritance may have a most important result in the elimination of the last trace of the doctrine of preformation from our conceptions of the germ plasm. It seems to me also probable that the consistent study of the so-called unit characters is tending rapidly to the overthrow of all corpuscular theories of heredity, and that with a proper understanding and interpretation of the Mendelian factors we may finally be freed from these confusing molecular chemical analogies in the study of the germ plasm.

There are certain broad inconsistencies in the doctrine that the characters of the whole organism as such are represented in any fashion by units of the germ plasm, which should always be borne in mind. Most conspicuous of these is the fact that there is no proportion between either the number of the chromosomes or their mass and the complexity of the organism to which they belong. The simplest algae and fungi may have as many chromosomes and, proportionally to the size of the cell and nucleus, as large chromosomes as some flowering plants. Allowing for a large amount of possible ultra-microscopic organization, such disproportions are not consistent with any corpuscular theory of heredity. It may well be that just as many of the so-called unit characters of Mendel and De Vries relate to the diffuse properties of the organism, as a whole, so the hereditary factors representing them depend on diffuse qualities of the cells as wholes in their interactions with each other. Such a view is not inconsistent with the doctrine that the chromosomes are the physical basis of heredity. We should perhaps, with Hertwig, more clearly distinguish between the heredity which determines the characters of the cells, epider-

mal, mesophyl, vessels, etc., and the determination of the qualities of the organisms as wholes which depend upon the interaction of these cells and which only indirectly represent and are represented by the organization of the cell and germ plasm. A leaf can not be represented directly in a cell, but the color of the leaf may be represented in the color of the cell, and its size may be determined by the capacity of the cell to divide and grow. Such Mendelian unit characters as color, length of life, etc., are properties of individual cells and agree with Detto's conception of metidentical characters which become by multiplication of the cells more or less diffuse properties of plants as wholes or organs as wholes.

It is easy to distinguish the heredity of the cell form as such from the heredity of the form of the many-celled colony. No one thinks now of asserting that the organization of the cell is identical with that of the many-celled individual. That dogma of the old preformationists disappeared with the improvement of the microscope. If we can, however, fix clearly in mind that such representation of the adult organism as is present in the egg in no way resembles in space configuration or in complexity the arrangement of organs and tissues in the adult animal or plant, we can attack the problem of form development as it really exists, and free from many encumbering traditions of preformation and epigenesis.

There can be no doubt that the cell and nucleus have a highly complex mechanical organization. It is a commonplace of histology that cell and tissue structures are relatively constant through genera and families—regardless of variation in the size and form of organs and of the plant as a whole. Cell size is also relatively constant through genera and even families.

Quantitative variations in the size of leaves, seeds, etc., are due to the number of cells they contain, and this, of course, depends on the number of times the cells have reproduced themselves by division. In some cases Mendelian characters can thus be identified with qualities of the cells.

The attempt from the standpoint of Mendelian conceptions of dominance and segregation to analyze the behavior of the generalized qualities of plants and their parts in development and heredity has been stimulating to research in a high degree, but the attempt to express the results of such analyses in terms of unit characters may be found to be only a relic of the preconceptions of the earlier corpuscular and preformational theories of heredity. Many Mendelians are inclined to think of their germ plasm as merely chemical in its essential constitution and I have referred above to the uncertainty of the evidence as to any ultramicroscopic organization of the nuclear chromatin of the cell. With the clarification of our conceptions in the domain of colloid chemistry we may hope to gain new viewpoints which will be more serviceable in the interpretation of biological facts than the conceptions of atoms and molecules which have so far dominated the corpuscular theories of protoplasmic structure. But we must also expect, perhaps, that the real distinctions between the organization of protoplasm with its long history of slow evolution and the *in vitro* aggregates of the chemist will be emphasized rather than obliterated.

R. A. HARPER

COLUMBIA UNIVERSITY

SCIENTIFIC NOTES AND NEWS

DR. FRANZ BOAS, professor of anthropology at Columbia University, has been given the doctorate of science by Oxford University.

THE Stevens Institute has conferred its doctorate of engineering on Professor Charles F. Scott, who holds the chair of electrical engineering in the Sheffield Scientific School of Yale University.

THE University of Manila has conferred a doctorate of science on Father José Algué, director of the Weather Bureau.

AMONG the degrees conferred by Columbia University, at its recent commencement, was the doctorate of letters on Dr. John Grier Hibben, president of Princeton University; the doctorate of science on Colonel George W. Goethals, chief engineer of the Panama Canal, and the degree of master of science on Dr. S. S. Wheeler, president of the Crocker-Wheeler Company.

KING GEORGE has conferred a knighthood on Mr. Harry James Veitch, distinguished for his work in horticulture.

THE board of trustees of the University of Alabama at their meeting on May 30, 1912, relieved Dr. Eugene A. Smith, professor of mineralogy and geology, of active class-room work, in order that he might devote his whole time to the Geological Survey and to the up-building of the museum of Smith Hall, the new building named in his honor and devoted to geology and natural history. Dr. Smith is retained in the university as head of the department of geology and as director of the museum. The teaching is turned over to Dr. Wm. F. Prouty, professor of geology, and his assistants. This action of the board of trustees was based on the request of Dr. Smith and the recommendation of President Denny.

MR. OLIVER B. HOPKINS, who recently received his Ph.D. degree at Johns Hopkins University, has been appointed assistant state geologist of Georgia to fill the position made vacant by the resignation of Dr. T. Poole Maynard.

T. R. ARKELL, associate professor of animal husbandry at the New Hampshire College, has resigned to accept a position with the Canadian government as head of the sheep division in Ottawa.

PAUL RADIN, Ph.D. (Columbia, '11), has been appointed to the fellowship of the International School of American Ethnology and Archeology for research in anthropology in Mexico City.

DR. WILLIAM H. HALE, superintendent of public baths in Brooklyn, has been appointed to represent New York City at the International Public Bath Conference to be held in Holland from August 27 to 30.

DR. BURT G. WILDER, professor emeritus in Cornell University, lectured recently at the Charleston Museum. He spoke on the silk spider, and at the conclusion of his lecture took occasion to highly compliment the work of Dr. P. M. Rea, director of the museum.

DR. ARTHUR W. GOODSPEED, professor of physics in the University of Pennsylvania, will on June 13 give the commencement address at the South Carolina Military College, Charleston.

PROFESSOR HUGO MÜNSTERBERG, who has now sailed for Europe, gave an address on June 4 before the Naval War College in Newport, R. I., on "The Psychology of the Navy," and an address on June 5 before the American Association for Labor Legislation on "The Psychology of Industrial Efficiency."

PROFESSOR D'ARCY W. THOMPSON, professor of natural history at Dundee, has been appointed Herbert Spencer lecturer at Oxford for 1912.

AT a meeting of the Chemical Society at Burlington House on June 26, Sir William Tilden, F.R.S., will deliver a memorial lecture in honor of the late Professor Stanislaw Cannizzaro.

DR. ED. STRASBURGER, the eminent botanist, professor at Bonn, died on May 20, aged sixty-eight years.

DR. ALFRED PRIBRAM, professor of pathology in the German university at Prague, has died, aged seventy-one years.

THE U. S. Civil Service Commission announces an examination on June 29 to fill vacancies in the position of agriculturist at salaries ranging from \$2,000 to \$2,500, and as-

sistant agriculturist at salaries ranging from \$1,600 to \$1,800 a year, Office of Farm Management, Bureau of Plant Industry, Department of Agriculture.

FOLLOWING a meeting of the biological section of the Kansas State Teachers Association a committee has been appointed to study the teaching of biology in the high schools of the state. The members of the committee are: H. F. Roberts, *chairman*, Kansas Agricultural College, botany; I. D. Cardiff, Washburn College, botany; W. C. Stevens, Kansas State University, botany; C. E. McClung, Kansas State University, zoology; J. W. Scott, Kansas Agricultural College, zoology; O. P. Delinger, Manual Training Normal School, biology; L. C. Wooster, Kansas State Normal School, biology; Wyman Greene, Wichita High School, zoology; W. E. Ringle, Cherryvale High School, botany and zoology; E. J. Dumond, Garden City High School, principal of high school.

THE University Commission on Southern Race Questions was recently organized at Nashville, Tenn. It consists of 11 members, each a representative of a southern state university. Professor C. H. Brough, of the University of Arkansas, was elected president and Professor William M. Hunley, of the University of Virginia, secretary. The next meeting will be held on December 19 at the University of Georgia, Athens, Ga. The chief object of the commission is to study the negro in his relation to southern life. The commission was organized through the efforts of Dr. James H. Dillard, president of the Jeans fund and director of the Slater fund, of New Orleans.

MR. PETER A. B. WIDENER, of Philadelphia, has set aside a fund of four million dollars for an endowment for the Widener Home for Crippled Children, which he had previously established with three million dollars. The present gift is in memory of his son, Mr. George D. Widener, who perished on the *Titanic*. His grandson Mr. Harry Elkins Widener, who also perished on the *Titanic*, has bequeathed his valuable library to Harvard University, and the family will erect a wing to the library building to house it.

THE Sleeping Sickness Bureau under the British government will hereafter be known as the Tropical Diseases Bureau. The new bureau will deal with all exotic diseases which are prevalent in tropical and subtropical regions, and will publish at frequent intervals a *Tropical Diseases Bulletin*, which will take the place of the present *Sleeping Sickness Bulletin*. As the *British Medical Journal* states, the Sleeping Sickness Bureau had its origin in the International Conference on Sleeping Sickness held in London, under the presidency of Lord Fitzmaurice, in June, 1907, and March, 1908, to concert measures for the control of that disease, which was spreading rapidly in tropical Africa. It was then proposed to have a central international bureau "to extract and circulate all new literature on sleeping sickness." This project fell through, because the delegates were not unanimous as to the seat of the bureau, or even the necessity for its separate existence. Arrangements were therefore made by Lord Elgin, then colonial secretary, for the establishment of a British Bureau, maintained by imperial funds, with a contribution from the Sudan government. The bureau, having outgrown the accommodation provided by the Royal Society, will have its quarters at the Imperial Institute.

UNIVERSITY AND EDUCATIONAL NEWS

LORD IVEAGH has given £10,000 to the University of Dublin, as an endowment fund for the department of geology and mineralogy.

THE University of Cincinnati held its thirty-fourth annual commencement exercises on June 4. A feature of the ceremonies was the official presentation to the university of the new engineering building, power plant and gymnasium and the Carson athletic field.

THE Harper Memorial Library of the University of Chicago was dedicated on June 11. The leading events of the services were a historical statement by President Harry Pratt Judson; a memorial address by Dean Albion W. Small, head of the department of sociology;

an address on behalf of the alumni by Mr. Donald R. Richberg, '01; a poem by Professor Edwin H. Lewis, Ph.D., '94; an address by Henry E. Legler, librarian of the Chicago Public Library; an address by Mr. Charles A. Coolidge, of the firm of Shepley, Rutan & Coolidge, architects of the building, and an address by James B. Angell, president emeritus of the University of Michigan. Mr. Franklin MacVeagh, secretary of the treasury, will deliver the address at the Convocation, which will be held in Harper Court at 3 P.M.

THE main building of the Agricultural and Mechanical College of Texas was destroyed by fire on May 27, between the hours of two and four in the morning. This building was erected in 1876 at a cost of \$100,000. It contained the administration offices, the library and class rooms for three departments.

A DORMITORY consisting of two, three, four and five-room apartments for married students has been established at the University of Chicago.

DR. FREDERICK J. E. WOODBRIDGE, professor of philosophy, has been appointed dean of the graduate faculties of Columbia University.

AT the Massachusetts Institute of Technology the William Barton Rogers professorship of economic geology has been established as a memorial to the founder of the institute, and with a portion of the bequest of Mrs. Rogers. Mr. Waldemar Lindgren, chief geologist of the U. S. Geological Survey, has been elected to this chair. In the same department Dr. Charles H. Warren has been advanced to be full professor and Dr. Frederick H. Lahee, of Dartmouth College, and Mr. John D. Mackenzie, of Cornell University, have been called as instructors. Professor T. A. Jaggar, Jr., as has already been noted in *SCIENCE*, will spend about five years as director of the Hawaiian Volcano Observatory. Promotions at the institute have been made as follows: To full professorships: F. J. Moore, organic chemistry; C. L. Adams, drawing and descriptive geometry; O. E. Fuller, theoretical and applied mechanics; C. F. Park, of mechanism, and W. A. Johnson, theoretical and applied

mechanism. To associate professorships: W. K. Lewis, chemical engineering; C. W. Berry, heat engineering; H. W. Hayward, theoretical and applied mechanics, and C. J. Riley, heat engineering. To assistant professor: R. P. Bigelow, zoology and parasitology; H. K. Burrisson, mechanical drawing and descriptive geometry; W. H. James, mechanical drawing; L. S. Smith, theoretical and applied mechanics; C. R. Hayward, mining engineering and metallurgy, and N. C. Page, physics. Research associate Charles A. Kraus has been made assistant professor of physico-chemical research; assistant J. P. Maxfield instructor in physics and assistant Franz Schneider, Jr., instructor in biology and public health.

STEPHEN S. COLVIN, Ph.B. (Brown, '91), Ph.D. (Strasburg, '97), professor of psychology in the University of Illinois, has accepted a chair in educational psychology in Brown University, newly established in cooperation with the State Board of Education with the assistance of an appropriation made by the state legislature.

DR. A. S. PEARSE will succeed Professor S. J. Holmes in the zoological department of the University of Wisconsin.

NEW instructors in the department of anatomy of the University of Pittsburgh Medical School are announced as follows: Edgar Davidson Congdon, A.B., A.M. (Syracuse), Ph.D. (Harvard), instructor in anatomy in the Cornell Medical School, New York City, N. Y., and Otto Frederick Kampmeier, A.B. (Iowa), Ph.D. (Princeton), fellow in comparative anatomy at Princeton.

DR. BERTRAM G. SMITH, during the past year a graduate student in Columbia University, has been appointed assistant professor of zoology in the Michigan State Normal College at Ypsilanti.

MR. C. M. HILLIARD, who has been teaching bacteriology for two years at the College of the City of New York, has resigned to accept a position as assistant professor of bacteriology and sanitary science at Purdue University. Mr. Hilliard's place at the City College will be taken by Dr. W. W. Browne, who takes

his doctor's degree with Professor Gorham at Brown University this spring.

DR. O. D. VON ENGELN has been promoted to an assistant professorship of geography at Cornell University.

DR. GRAHAM EDGAR has been promoted to be associate professor of chemistry at the University of Virginia.

PROFESSOR J. L. GILLIN, of the State University of Iowa, who has been teaching sociology there for the past five years, has accepted a call to the University of Wisconsin, service to begin with the opening of the next school year. The work of Professor Gillin at the University of Wisconsin will be to teach courses in sociology during one semester of the year and the remainder of his time will be spent as secretary of the department of general information and welfare, one of the four departments in the extension division of the university.

MR. M. POWER, lecturer in mathematics at Dublin, has been appointed professor of mathematics at Galway.

PROFESSOR F. G. DONNAN, Muspratt professor of physical chemistry at Liverpool, has declined the chair of chemistry at University College, London, vacant by the retirement of Sir William Ramsay, K.C.B.

DISCUSSION AND CORRESPONDENCE

THE NATURE OF THE INHERITANCE OF HORNS IN SHEEP

To our communication in *SCIENCE* of March 8 Professor Castle has offered¹ a vigorous critique. A wordy continuation of the discussion of a matter most of whose points can be easily settled by experiments now under way would be to imitate the methods of an old continent and a past epoch in biology. We may add only that the simple Batesonian formula which Dr. Castle seems to find sufficient appears from the context no more fully satisfactory to the formulator than to ourselves. As to the effect of castration in eliminating horns in males, this is, apparently, a special result in Merinos and other races

¹ *SCIENCE*, April 12.

possessing horns typically or prevailingly in the males only. Darwin has discussed this matter in the "Descent of Man," Chap. XVII.; and correspondence recently had with breeders of Merinos confirms Darwin's (and Castle's) statements. In Dorset Horns, on the other hand, as in reindeer and cattle, castration has only a modifying effect.

Finally, we wish to acknowledge kind suggestions (in letters) from Professor T. H. Morgan and Mr. A. H. Sturtevant, and we trust they will publish their formula, which differs in several respects from ours. The principal difficulty they find with our formula is that it does not account for a race in which, in successive generations, all males are horned and all females are hornless. Such a race of Merinos there may be; but there is much evidence that in many long and carefully bred strains of Merinos the standard of hornlessness in the ewes is maintained only by hurrying the horned ewe lambs to the butcher.

AGRICULTURE IN SCHOOLS

TO THE EDITOR OF *SCIENCE*: I note in the issue of *SCIENCE* dated April 27, 1912, an announcement concerning the signing of the Harte bill providing for the establishment of a New York State School of Agriculture on Long Island. The memorandum by the governor appended to this bill, as quoted in *SCIENCE*, might mislead the reader in regard to the status of the teaching of agriculture in New York.

The Cortland State Normal School has had in operation for nearly a year a course for training teachers of agriculture. This course is open only to graduates of approved high schools who have had practical farm experience. The course is for two years' work. It may be that the fact that the governor has not been called upon to sign a bill of special appropriation for the establishment of this course has been the cause of his overlooking it.

In regard to the high school situation I wish to call attention to the fact that seven-

teen schools have a full four-year high-school course in agriculture and will therefore receive \$500 each in accordance with Article 22, Education Law of 1910. In addition to these special vocational courses in established high schools twenty-three high schools give some instruction in agriculture.

L. S. HAWKINS

CORTLAND, N. Y.

SCIENTIFIC BOOKS

The Absorption Spectra of Solutions of Comparatively Rare Salts Including those of Gadolinium, Dysprosium and Samarium, the Spectrophotography of Certain Chemical Reactions and the Effect of High Temperature on the Absorption Spectra of Non-aqueous Solutions. By HARRY C. JONES and W. W. STRONG. Publication No. 160 of the Carnegie Institution of Washington.

In this monograph the authors present the results of their recent spectrochemical investigations carried out along the three following distinct lines: (1) The mapping of the absorption spectra of certain comparatively rare substances, (2) the spectrophotography of some oxidation reactions, and (3) the effect of relatively high temperatures on the absorption spectra of alcoholic solutions.

In an introductory chapter a brief review is given of some important spectrochemical investigations of the last decade concerning the nature of the emission and absorption centers of light; the connection between these centers and molecular and atomic structures; the effect of ionization and recombination on these centers, and the effects that can be produced by physical and chemical agents upon the constitution of the emission and absorption centers.

The general method of experiment was similar to that employed by Jones and his co-workers in their previous investigations. For experiments at high temperatures a new form of absorption cell was devised, for a description of which the original monograph must be consulted. Through the kindness of Professor Urbain sufficient quantities of the oxides of samarium, dysprosium and gad-

olinium were loaned the authors to enable them to prepare the various salts whose solutions they wished to study.

An examination of the spectrograms in this and the preceding monographs shows that in general the absorption spectra of various salts of the same element are very similar. With high dispersion the minute structure of the bands and groups of bands is shown to be very different for different salts of the same element, this being especially true of the salts of neodymium. Beers's law has been shown to hold approximately for nearly all solutions of a single neutral salt in a single solvent. Each solvent is characterized by a definite absorption spectrum, and when a salt is dissolved in a mixture of varying proportions of two solvents only two definite absorption spectra appear, a result which the authors interpret as an indication of the formation of definite compounds of solvent and solute or "solvates."

In their study of oxidation phenomena uranous salts were subjected to the action of both weak and strong oxidizing agents, the salts being dissolved in single and mixed solvents. On dissolving uranous chloride in a mixture of alcohol and water, the bands characteristic of both solvents appear simultaneously. A mild oxidizing agent was found to oxidize the "hydrated" salts and leave the "alcoholated" salts unchanged, while with a strong oxidizing agent both "hydrated" and "alcoholated" salts were oxidized to the uranyl condition.

Rise of temperature has been shown to cause a widening of the bands in solutions of a pure salt in a single solvent, the edges of the bands becoming hazy. When several salts are dissolved in the same solvent the bands become weaker as the temperature rises. In general the center of intensity of the single bands remains unaltered with rise in temperature.

This recent publication of Jones and his associates is another valuable contribution to the literature of spectrochemistry and will undoubtedly find a place on the book-shelves of those engaged in spectroscopic investigations. No little credit is due the printer for the ex-

cellence of his work, without which the plates would be of much less value.

FREDERICK H. GETMAN

Historical Papers on Modern Explosives.

By GEORGE W. MACDONALD. Whittaker & Co., N. Y. 1912. Pp. 192. \$2.50 net.

When the age of the world as fixed by the most recent observers, such as Becker and Clarke, the probable length of time it has been inhabited by man, and the important part which chemistry played, both in the creation of the earth and of its inhabitants, is considered, it is an amazing thing that man was so very slow in assembling a systematized knowledge of chemistry and especially slow in recognizing those compounds which are reservoirs of energy, for though compounds of this kind, such as the nitrosubstitution compound, picric acid, discovered by Hausmann in 1788, were described in the latter part of the eighteenth century, it was not until the opening year of the nineteenth century, in which Howard discovered mercuric fulminate and demonstrated its properties, that man apparently began to realize that energy could be stored up in individual compound molecules which was ready for release at command, so that it might be employed like the bent bow, the coiled spring, the head of water, the wind, or the energy of man or animals applied through the many mechanical devices then invented, or mixtures of substances, such as gunpowders, to do work.

This new conception of a capacity with which compound molecules might be endowed was, in the middle of the nineteenth century, reinforced by Schönbein's discovery of cellulose nitrates and Sobrero's discovery of glyceryl nitrates; and the discovery and recognition of the value of molecules so constituted to mankind in the accomplishment of work has gone on with continued acceleration ever since, for masses of the mercuric fulminate, cellulose nitrates, glyceryl nitrates, alone or compounded into mixtures such as the many dynamites, smokeless powders and permissible explosives, have been put to do work in engineering projects and in military operations,

and they have, when wisely used, materially increased the resources of man in his contest with the material world in which he is placed and environed.

The period covered by MacDonald in the book under review is from 1800 to 1887 and it deals with the discovery and development of the three explosives last enumerated. This was a period of marked scientific and technical activity with regards to these bodies and much was published regarding them in widely scattered publications, some of which are now difficult of access, and because of this, and further because the earliest literature "often contains observations and experiments which are generally considered to be the results of much later investigation" the author has brought them together here after having published them as separate articles in *Arms and Explosives*.

Mr. MacDonald has not given reprints but rather condensed résumés in which he has divided single articles into several smaller ones and introduced comments of his own. Further he has drawn his material from patent literature and unpublished correspondence as well as from scientific journals, and recast or "reduced tabulated results to statements of fact." It will be seen therefore that the book is not authoritative, even to the extent that carefully supervised reprints would be, and that its usefulness is limited.

There appears a lack of proportion in the treatment since 149 out of the 192 pages are devoted to gun cotton and 98 of these to Abel's work leaving Schönbein the discoverer, and von Lenk, whose pioneer work in Austria was presented freely and in detail to the Committee of the British Association, quite in the background. In fact there is a distinctly British tendency permeating the book.

CHARLES E. MUNROE

Insect Pests of the Farm, Garden and Orchard. By E. DWIGHT SANDERSON. New York, John Wiley & Sons. 1912. \$3.00.

The author explains in the preface how his attempt to revise his former book "Insects Injurious to Staple Crops" finally resulted in

extending its scope and practically rewriting it, until the present volume came out of it. Entomologists, orchardists, farmers and teachers are all indebted to Professor Sanderson for bringing together the scattered up-to-date information presented in this book. Many control methods and remedies recommended in previous works have recently been superseded and are therefore out of date.

The subject matter of the volume in question is well presented, and the illustrations for the most part are satisfactory, though one questions if it is not better to use photographs entirely of spraying apparatus rather than the trade cuts from manufacturers' catalogues. Some other ancient cuts have also been used which do not add to the usefulness or attractiveness of the volume. Most of the illustrations are excellent, a goodly number are original, and many have appeared before in entomological journals and experiment station bulletins, due credit being given. It is perhaps impossible to prepare and print a work of this magnitude without finding some errors in it, but the errors in this volume are mostly typographical, and can easily be corrected in future editions. A few of the illustrations are badly printed, but in most respects the mechanical production of the book leaves nothing to be desired.

The work should supply a distinct need, and ought to be placed on the shelves of all libraries.

W. E. BRITTON

TERMS USED TO DENOTE THE ABUNDANCE OR RARITY OF BIRDS

WHEN reading lists of birds, which indicate their abundance or rarity, it is often very difficult to tell just how common or how rare a bird is, for it is seldom that any two people use the same scale of terms. In fact few have any definitely graded scale, most preferring to write them as they are needed, and consequently, without realizing, they have a long illogical list of terms. Those most frequently adopted are given below. I have limited myself to eight, which are: abundant, common, frequent, uncommon, occasional, rare, scarce

and irregular. Together with other terms that are used I have given my reasons for not using them. Those which I have selected have been proposed chiefly, and all agreed to by Mr. C. William Beebe.

Abundant.

Very Common is the same as Abundant, for Abundant means More Common than Common.

Common.

Plentiful means the same as Abundant or Common.

Usually Common or Usually Rare are the same as Common or Rare, for we are writing about what the bird usually is, so Usually may be omitted.

Quite Common. The real meaning of Quite is "completely" or "wholly." It is wrongly used to indicate "to a considerable extent." Thus Quite Common, correctly used, means no more than Completely Common, or simply Common.

Not Uncommon is equal to Common.

Tolerably Common is usually used to mean Fairly Common, but thus used it is a very meaningless word, as tolerably means that which can be endured. If one wishes to use it as meaning Fairly Common, he can just as well use the latter word or, instead of these, Frequent.

Frequent.

Often Seen is the same as Frequent.

Usually Tolerably Common is the same as Tolerably Common, which is the same as Frequent. Fairly Plentiful is the same as Fairly Common. Fairly Common is the same as Frequent.

Uncommon.

Infrequent is the same as Uncommon or Occasional.

Not Common is Uncommon.

Occasional.

• Sometimes Seen is Occasional.

Accidental is Occasional or Rare.

Rare.

Very Rare is using an unnecessary adverb, for Rare is Very Rare, and to use the latter, only makes a list more confusing and difficult to understand.

Scarce.

Scarce does not mean the same as Rare, but indicates that the bird mentioned was at some previous time Common, but that it has since decreased in numbers until it is now Rare.

Very Scarce means Scarce (Very is unnecessary).

Irregular.

Irregular indicates that at times the bird may be Common and at other times Rare. Often this has to be used in connection with one of the other seven terms. In such cases it is often necessary to add Usually; as: Cross-bill, Irregular, Usually Rare.

Of course it is not intended that these terms should always be used by themselves. One may use them, when necessary, in conjunction with other words; as, Common Migrant, Scarce Resident, etc.

JOHN DRYDEN KUSER

BERNARDSVILLE, N. J.

TRIVALENT PLATINUM

THE first evidences of the existence of compounds in which platinum acts with a valence of three were found about two years ago by Wöhler. On carefully chlorinating PtCl_2 or dechlorinating PtCl_4 at 390° , a greenish-black powder was formed which had the formula PtCl_3 . This dissolved slightly in cold water, but more rapidly in hot, with the formation of an acid, $\text{H}_2\text{PtCl}_5\text{O}$, some hydrolysis also taking place. By precipitating with soda, a pure hydrated sesquioxid was obtained, but this could not be dehydrated without decomposition. When the hydrate was dissolved in acid a mixture of chloroplatinous and chloroplatinic acids was formed. Wöhler found, however, that when a dilute solution of cesium and a mixture of chloroplatinous and chloroplatinic acids was formed. Wöhler found, however, that when a dilute solution of cesium and a mixture of chloroplatinous and chloroplatinic acids was formed, a dark-green powder is precipitated, of the composition Cs_3PtCl_6 , which has a strong tendency to decompose into the chloroplatinite and chloroplatinate.

This work has been strikingly confirmed in a paper read by Levy before the Chemical Society (London) on March 25. Levy was working on the copper-red iridescent salt, discovered by Hadow, which is formed when chlorine or bromine is added to a solution of potassium cyanoplatinite. To this Hadow gave the composition of $5\text{K}_2\text{Pt}(\text{CN})_6 \cdot \text{K}_2\text{Pt}(\text{CN})_6 \cdot \text{Br}_2$. The character of the salt Levy confirmed, but its formula should be $6\text{K}_2\text{Pt}(\text{CN})_6 \cdot \text{K}_2\text{Pt}(\text{CN})_6 \cdot \text{Br}_2$. Levy also found that when the cyano-

platinite is oxidized by lead or manganese dioxid in the presence of sulfuric acid, a similar compound is formed, but containing SO_4 instead of Br_2 , which behaves like the sulfate of a feebly electropositive element; in other words the group $(\text{K}_2\text{Pt}(\text{CN})_6)$ acts like a bivalent positive ion. More interesting was the result when hydrogen peroxid and other peroxids were used as the oxidizing agents. With the potassium cyanoplatinite there is at once formed a well-defined, crystallized double salt of the composition $3\text{K}_2\text{Pt}(\text{CN})_6 \cdot \text{KPt}(\text{CN})_6 \cdot 6\text{H}_2\text{O}$, which is not further acted on by hydrogen peroxid. When, however, perhydrol is used the oxidation to $\text{KPt}(\text{CN})_6$ is complete, and a series of similar salts was prepared. With the free cyanoplatinous acid, $\text{H}_2\text{Pt}(\text{CN})_4$, the oxidation to $\text{HPT}(\text{CN})_6$ by hydrogen peroxid is complete. Here we have an acid and its salts in which the platinum acts, as in Wöhler's halid salts, as trivalent, and its formula may be written $\text{HCN} \cdot \text{Pt}(\text{CN})_3$. These cyanoplatinates would bear the same relation to the cyanoplatinites as the ferrocyanids bear to the ferricyanids. This is unexpected, as it would naturally be inferred that in accordance with the analogy furnished by the haloplatinites and haloplatinates, the cyanoplatinates would have the formula $\text{M}_3\text{Pt}(\text{CN})_6$. No evidence was found of similar compounds of the type $2\text{MCN} \cdot \text{Pt}(\text{CN})_3$ or $3\text{MCN} \cdot \text{Pt}(\text{CN})_3$. On treatment with KCN or with any alkali, decomposition ensued, with the regeneration of the cyanoplatinite.

J. L. H.

*SPECIAL ARTICLES*SIMPLE DEMONSTRATION APPARATUS FOR THE
INFRA-RED SPECTRUM

MOST teachers of experimental physics in this country do not attempt to illustrate the optical properties of matter in the long wavelength invisible spectrum, for the reason that the standard detecting instruments, the bolometer, thermopile, radiometer or radiomicrometer, are not particularly well suited for use in the lecture room where great stability is not usually ensured. Moreover, unless the lec-

turer in general physics happens to have had considerable experience in the use of these instruments they are likely to cause annoying delays in the generally hurried preparation for an experimental lecture.

For demonstrative purposes the simpler an instrument is the better, provided it may be made sufficiently sensitive, because in an elementary lecture course there is danger of the student losing sight of the very phenomenon which an instrument is designed to render apparent if his attention is divided between the instrument and the phenomenon. I have recently devised a substitute for the

bolometer or other detecting instrument which meets the requirement of simplicity in an eminent degree, as it consists only of an india-rubber band, a glass fiber, a small mirror and a small piece of plate glass. It may be put together and adjusted in less than a minute and may be mounted anywhere on the lecture table, as it does not require a very stable support.

It is well known that the elasticity of

stretched india-rubber increases with increasing temperature so that on heating the stretched piece it shortens. An india-rubber band about one millimeter wide is stretched to nearly double its length about the rectangular frame of plate glass *FGHI* and a glass staff *DE* (which should be as straight as possible and of a diameter such that it is just stiff enough to support the small mirror *E* of silvered microscope cover-glass of about two or three square millimeters area) is placed, as shown in the figure, under the rubber band at its middle point *B*. If the portion *AB* be heated the staff *DE* will roll on the frame towards the edge *FG*, and a beam of light reflected from the mirror *E* may be used to indicate (and magnify) this contraction of the india-rubber band. A change of temperature of both portions of the band, *AB* and *BC*, will be without effect on the position of the mirror *E*. This ensures steadiness of "zero." The inertia of the moving parts is small and the change in elasticity of the rubber follows the changes of temperature without any very noticeable lag, so that the instrument is both "dead beat" and sufficiently quick to respond to differences in temperature between the sections *AB* and *BC*, and insensitive to changes in temperature which affect both of the sections.

For use as a substitute for the bolometer it is sufficient to clamp the rectangle *FGHI* in a vertical plane and to cause the spectrum to pass across the portion *AB*—the rise in temperature of the strip *AB* is approximately proportional to the energy present in the portion of the spectrum which covers *AB* and, the change in elasticity being approximately proportional to the change in temperature, the deviation in the beam of light from the mirror is approximately proportional to the energy present in the particular part of the spectrum which covers the strip.

For demonstration in the spectral region between the red and wave-length $\lambda = 3\mu$ where glass begins to be opaque the arrangement shown in the figure is convenient—*N* is a Nernst filament mounted in a vertical plane V —*h*₁ and *h*₂ large short-focus glass lenses and

P a large glass prism (a 60° prism 3 inches high and 4 inches on the slant face works well, though one half this size would do, particularly if very short-focus lenses were used). *M* is the plate glass rectangle *FGHI* mounted vertically at the principal focus of the lens *h*, so that the colored images of the Nernst filament are parallel to the band *AB*.

It is well to mount the prism so that it may be gradually rotated about the vertical axis through *O*. If large lenses and a large prism are available it is well to use the long 220-volt Nernst filament and to choose the rubber band so that the length *AB* is about equal to the length of the Nernst glower used.

As the prism is rotated and the spectrum moves across the band the deviation of the beam of light from the mirror *E* increases and reaches a maximum and it is easy for the audience to see that this maximum is reached when no visible light is falling on the band *AB*.

By setting the prism so that the red of the spectrum falls on the band, and noting the change in the deviation of the beam of light from the mirror *E* as various substances are placed in front of the Nernst glower, and then noting the changes produced by the same substances when they are introduced under the condition that invisible long wave-length energy falls on the band, it can be readily shown that not all substances which are transparent are diathermanous.

AUGUSTUS TROWBRIDGE

PRINCETON UNIVERSITY

THE AMERICAN SOCIETY OF ZOOLOGISTS

THE Central Branch of the American Society of Zoologists met at the University of Illinois, Urbana, Ill., April 5 and 6, 1912.

The following officers of this branch were elected for the ensuing year:

President—H. B. Ward, University of Illinois, Urbana, Ill.

Vice-president—C. M. Child, University of Chicago, Chicago, Ill.

Secretary-treasurer—W. C. Curtis, University of Missouri, Columbia, Mo.

Additional Members of the Executive Committee—C. E. McClung, University of Kansas, Lawrence,

Kans. (for three years); H. F. Nachtrieb, University of Minnesota, Minneapolis, Minn. (for two years).

At the business meetings, on April 5, action was taken as follows:

Resolutions upon the death of Professor C. O. Whitman as spread upon the minutes of the society were read.

By vote of the society the committee on the form of presenting papers for publication, Dr. C. E. McClung, chairman, was continued. No report was made.

The following report of the committee on nomenclature, Professor C. C. Nutting, chairman, was read and unanimously adopted:

The Committee on Nomenclature appointed at the Iowa City meeting of the Central Branch of the American Society of Zoologists reported last year a plan whereby various zoological organizations in America might unite in an effort to influence the International Commission on Nomenclature in the direction of securing greater flexibility in the interpretation of the rules. The committee begs to report that after extended correspondence it has reached the unanimous conclusion that it is impossible to secure any modification of the present practise through the International Commission itself, and that the officers of that commission maintain that its hands have been tied through action recently taken by the International Congress. It appears consequently that recourse to the International Congress itself offers the only remedy for the adjustment of the difficulties. That these are increasingly apparent becomes evident by the protests and appeals which are finding expression in various form from individuals, from groups of workers and from societies not only in this country, but in various other parts of the world, as a result of which several propositions have already been formulated for presentation to the meeting of the International Congress at Monaco in August, 1913.

The Committee on Nomenclature reports to the American Society of Zoologists, Central Branch, requesting at this time:

1. Authority to ask from the membership of the Central Branch an expression of opinion on the following question: Do you favor the strict (inflexible) application of the priority rule as the latter is now interpreted by the International Commission on Nomenclature?

2. The adoption of the following resolution for transmission to the International Zoological Con-

gress at Monaco in 1913: All propositions for amendments to rules on nomenclature which are approved by a majority of the International Commission on Nomenclature shall be submitted to the International Congress for final decision by vote in open meeting. In case it appears that any legislation to the contrary has been adopted by a previous International Congress, the International Congress at Monaco is respectfully urged to reconsider and repeal such action.

Signed, S. W. WILLISTON

H. B. WARD

C. C. NUTTING (*chairman*)

The treasurer of the society was authorized to allow the committee on nomenclature funds sufficient to obtain a census of opinion regarding the question of priority in nomenclature.

Professors Lillie, Lefevre and Patterson were appointed a committee to draw up resolutions upon the death of Professor Montgomery.

The following papers were presented at the meeting, either in full or by title:

Fertilizing Power of Portions of the Spermatozoon: FRANK R. LILLIE, University of Chicago.

(Published in *SCIENCE*, March 22, as part of the report of the proceedings of the Eastern Branch.)

On the Presence of Independent Mesenchymal Lymph Spaces in Turtle Embryos as Determined by the Study of Injections and Sections: FRANK A. STROMSTEN, University of Iowa.

The results set forth in this paper were based on the study of embryos of the loggerhead turtle. The blood-vascular system had been injected through the vitelline vessels. The lymphatics were injected through the jugular lymph-sacs, using the methods of Knower and Sabin. Serial sections of these embryos show that the peri-aortic lymph plexus is always preceded by a series of independent spaces which can neither be injected from the lymphatic nor the blood-vascular systems. Proofs, based on a series of photomicrographs and wax reconstructions, were given to show that these independent spaces are derived directly from the original intercellular mesenchymal spaces, and that they finally become part and parcel of the lymphatic plexus.

More Trouble for the Systematist: C. C. NUTTING, University of Iowa.

Note on the Embryonic Development of the External and Internal Carotids of the Chick: WM. A. LOCKY, Northwestern University.

The Morphology of the Sympathetic Neurons in the Myenteric and Submucous Plexuses: ALBERT KUNTZ, University of Iowa.

In the myenteric and the submucous plexus in the small intestine of the cat and the dog sympathetic neurones of several distinct types may be observed. The two types which are most evident may be characterized as follows: (a) neurones which are irregular and more or less angular in outline possessing numerous varicose dendrites which vary greatly in length and in diameter and usually show numerous short branches; (b) neurones which are more regular in outline, possessing fewer dendrites which are usually long and slender and show only few branches. Neurones of both these types are present in considerable numbers in the myenteric plexus. In the submucous plexus the neurones of the second type preponderate.

The ganglia of these plexuses are variously connected by commissures in which may be traced both axones and dendrites. Fibrous commissures also connect the two plexuses with each other, while from the submucous plexus fibers may be traced into the plexuses surrounding the digestive glands and into the intestinal villi, where many of them, doubtless, terminate on cells of the digestive epithelium. Such terminations could frequently be observed, but in no case could an individual fiber be traced from its termination on the digestive epithelium back to the cell-body from which it arose.

The fibers terminating on the digestive epithelium, doubtless, subserve a receptive function. They are probably the dendrites of neurones of the second type above described. These neurones would, therefore, be sensory in character. The axones of some of the neurones of the first type above described terminate directly on smooth muscle-fibers. These neurones are obviously motor in character. The distribution and the orientation of the neurones in these plexuses is obviously such as would be required by a system of local reflex arcs. That such a system of reflex arcs is present in the walls of the digestive tube has already been suggested by Dogiel, Müller and others. Indeed,

it is highly probable that the normal nervous control of the digestive functions is exercised primarily by the local sympathetic mechanism.

Amphimixis, Variability and Death; Some Facts and a Theory: L. B. WALTON, Kenyon College.

In connection with some studies on the variability of zygospores in *Spirogyra inflata* (Vauch.) formed by scalariform (amphimixis) and by lateral (quasi parthenogenesis) conjugation, certain facts are presented which allow an interpretation of the cause of death among organisms from a different standpoint than the generally accepted theory.

In 200 zygospores produced through the conjugation of cells of different filaments—sexual reproduction—the coefficient of variation is 9.5093 for length and 5.7471 for diameter. In the same number of zygospores produced by the fusion of adjacent cells of the same filament—comparable to asexual reproduction—the coefficient of variation is 11.9364 for length and 7.5376 for diameter, indicating for the given conditions that the cross-bred or sexually-produced zygospores, in themselves the young individuals from which the mature filaments arise, are relatively 20 per cent. less variable in length and 23 per cent. less variable in diameter.

Thus if amphimixis decreases variability, there is presented an interesting condition bearing not only on the problem of the origin of sex, but also on the origin of death, for the theory is equally applicable to the individual cell, whether isolated, as in the Protista, or associated in colonies, as in the higher animals and plants. The development of the body in multicellular organisms represents merely the development by asexual reproduction of an infinite series of cell individuals. Consequently the evidence suggests that *death occurs as the result of the continually forming body cells becoming so variable through the absence of control by amphimixis, that eventually some one group fails to meet the limits imposed by the environment, and these together with the remainder of the colony—the individual—perish.*

With a single exception, the available evidence is directly in accord with such a theory, although in general merely demonstrating that amphimixis does not increase variability (Warren, '99; Castell and Phillips, '03; Kellogg, '06; Wright, Lee and Pearson, '07). The investigations of Jennings, '11, on *Paramecium* seem to indicate that here conjugation increases variability. The evidence, however, was not altogether in harmony, in con-

sequence of which the subject was reserved for a future paper based upon additional investigations. Even granting that such is the case in *Paramecium*, where conjugation consists of a temporary union of gametes (conjugants), it would not necessarily follow that a similar condition would be found in organisms where a total and permanent fusion of gametes (copulants) occurred.

While it would seem that such a theory as here outlined is in advance of the earlier theories as to the cause of death which are purely speculative, there is need of additional data, and it is hoped that the several investigations now in progress may throw additional light on the subject.

On the Autonomic Nervous System of the Rabbit:

F. W. CARPENTER, University of Illinois.

The Variation and Ecological Distribution of the Shells of the Genus Io: C. C. ADAMS, University of Illinois.

Antero-posterior Dominance in Planaria: C. M. CHILD, University of Chicago.

In high concentrations of KCN, alcohol, ether and various other agents, which kill the animals within a few hours, the resistance of animals and pieces varies inversely as their rates of metabolism. In low concentrations, to which the animals become acclimated, the length of life varies directly as the rate of metabolism, because the animals or pieces with higher rate become more completely acclimated.

By means of these and other experimental methods the following conclusions have been reached concerning the dynamics of morphogenesis in *Planaria*: the anterior region has the highest rate of metabolism, at least during development, and from this a gradient in rate extends posteriorly; each zooid has a similar gradient of its own; because it has the highest rate of metabolism, the anterior region is dominant, both in morphogenesis and function, over the regions within a certain distance limit and in general any level is dominant over levels posterior to it and within a certain distance limit: the axial gradient in rate of reactions is the basis of organic polarity; by decreasing or eliminating this gradient heteromorphosis can be induced experimentally: the reaction-complex which gives rise to a head is the fundamental reaction-complex of the specific protoplasm.

The formation of a new head in the regulation of pieces of *Planaria* is not a restitution of a missing part, but the formation of a new individual head first and the new head region induces

the reorganization of the remainder of the piece. The head forms "in spite of" other old parts of the piece and not in correlation with them, but the new posterior end is the product of correlation with more anterior parts. In a series of similar pieces the frequency of head-formation and the character of the heads can be altered in either direction by agents which influence the rate of metabolism.

Observations on the Breeding Behavior of the Herring Gull: R. M. STRONG, University of Chicago.

Studies were made of the breeding behavior of the herring gull from the standpoint of modifiability, and especial attention was given to the voice of this bird. The report was illustrated by lantern slides. (To be published elsewhere.)

(1) *Maturation and Fertilization of the Armadillo Ovum.* (2) *Crucial Evidence of Parthenogenetic Cleavage of Ova during Follicular Atresia in the Armadillo:* H. H. NEWMAN, University of Chicago.

(1) The armadillo ovum is probably the most primitive Eutherian ovum known, in the sense that it shows a condition practically like that of the Marsupial *Dasyurus*. In the full-grown oocyte there is a cortex of formative protoplasm and a central deutoplasmic mass. During the process of maturation a radical change of polarity takes place, resulting in "telolecithal" condition upside-down. The deutoplasmic mass occupies the animal pole and the formative protoplasm lies at the vegetative pole in the form of a cap partially overlapping the deutoplasm. The maturation spindle is found in an equatorial position, i. e., as near the animal pole as possible without leaving the formative protoplasm. In other respects the maturation processes are essentially like those of other mammals. Only one fertilized egg was found, but this is very typical and is accepted as the norm for the species. There is but one male and but one female pronucleus and there are the usual two polar bodies. This furnished additional proof of the reality of polyembryony in the species.

The present investigation is the first study of maturation or fertilization processes in the Edentates. (To appear in *Biological Bulletin*.)

2. All previous observations concerning the alleged occurrence of parthenogenetic development in the mammalia have met with scant attention on the part of biologists. It is hoped that the present observations will meet a better fate. The following phenomena have been observed in ovarian ova

that have reached maturity but have been robbed of their chances of ovulation by the occurrence of pregnancy. The mature ovum, which has the condition described in the previous abstract, gets rid of its deutoplasmic mass by abstriction. The formative protoplasm then rounds itself up into a ball within which lies the large resting nucleus, probably the female pronucleus; the latter then forms a perfect cleavage spindle whose aster radiations invade the entire cell, and the first cleavage occurs. Equally unequivocal cleavage spindles occur in each of the first two blastomeres. Stages have been found with as many as four spindles visible at one time. In others two or three spindles and one or two resting nuclei occur in the same egg. The fate of the deutoplasmic material is peculiar and probably quite different from that in normal development. It fragments into a large number of cell-like bodies, with nucleus-like corpuscles composed of deutoplasmic granules, and at first forms a sheath around the formative cells. Subsequently these fragments are crowded between the blastomeres and bring about a condition of isolation of blastomeres. Evidently cleavage goes on considerably further, but, since there is at this time a tendency for stroma cells to enter the egg through breaks in the zona pellucida, it is impossible to be sure as to how much of the observed conditions are due to the development of the egg and how much is to be attributed to the activities of invading cells. The first few cleavages, however, are certainly the result of parthenogenetic development of the ovum. (To appear in *Journal of Morphology*.)

Preliminary Chemical Studies on Male and Female-producing Eggs of Pigeons. A Study of the Eggs of Forms in which the Dominance of Male and Female Sex and of White and Dark Color was Experimentally Determined by Professor C. O. Whitman: OSCAR RIDDLE, Carnegie Institution.

(Abstract published in *SCIENCE*, March 21, 1912, p. 462.)

Indications Regarding Differentiation from Tissue Culture Experiments: MARIAN L. SHOREY, Milwaukee Downer College.

Tissues of dogfish embryos from five to fourteen millimeters in length were found to grow equally well in saline solutions that contained, and those that did not contain, nutrient substances. As there seems to be no evidence that the embryonic cells of animals in which there is a distinct separation between the germ plasm and the yolk, as is

found in the dogfish, contain sufficient stored food to account for the amount of growth that occurs, the conclusion seems to be justified that the growing tissues receive their food supply from other tissues transplanted with them. Even when the culture medium contained both proteins and carbohydrates there was much more growth than when more than one kind of tissue was present.

In both my own experiments and in the published accounts of the work of others many tissues differentiate abnormally in the medium used, and in many other cases their identification with normal body cells seems at least to be doubtful. In other instances tissues which can be identified have been observed, but so far as I know these have never been found except when plasma was used or when more than one kind of tissue was present. The effect, therefore, either of the activity of these other tissues, or of their specific decomposition products, has not been excluded. This fact, taken in consideration with the instances of abnormal differentiation, while it does not demonstrate, seems to indicate that the differentiation of a cell depends not only on its own inherent properties, but also on the nature of its environment.

Some Recent Discoveries in Paleozoic Vertebrates:

S. W. WILLISTON, University of Chicago.

Some Early Embryonic Stages that Conclusively Demonstrate Polyembryonic Development in the Armadillo: J. T. PATTERSON, University of Texas.

The investigation reported in this paper had as an object the demonstration of polyembryonic development in the North American armadillo. It was shown that from late cleavage stages until after the two primary germ layers are laid down the differentiation of this egg represents a typical mammalian development. Upon becoming attached at the animal pole to the placental region of the mucosa the vesicle undergoes the process of "germ layer inversion," producing two secondary, incomplete vesicles, one lying within the other. The innermost of these soon becomes completed and may be called the ectodermic vesicle; the outermost remains incomplete on the placental side and is the entodermic vesicle. The region of the trophoblast which is in contact with the mucosa forms the Träger, while the distal or free part sooner or later sloughs off, leaving the entodermic vesicle directly exposed to the uterine cavity. The mesoderm arises as two pouches, situated at the right and left sides of the ectodermic vesicle. These expand and fuse together to form a char-

acteristic extra-embryonic body cavity, which occupies the space lying between the Träger and the proximal side of the ectodermic vesicle. The rudiments of the embryos arise from the ectodermic vesicle, and at first appear as two blunt outgrowths (the primary buds), arising from the right and left sides of the vesicle. Each primary bud, which lies directly above a mesodermic pouch, grows laterally and ventrally along the inner surface of the entodermic vesicle, and soon bifurcates at its distal end to produce two secondary buds, each of which represents the rudiment of an embryo. The secondary buds of the right side produce the pair of embryos previously designated the "dorsal" (III.) and "right-lateral" (IV.), while those of the left side form the "ventral" (I.) and "left-lateral" (II.). As a result of the failure of the primary buds immediately to complete division at their proximal ends, the two secondary buds of each side remain connected at these points. The further differentiation of each secondary bud to produce an embryo consists in its rapid extension as a finger-like process along the inner side of the entoderm towards the Träger, with which a placental connection is eventually established. The cavity of each secondary bud forms the amniotic cavity for the embryo, and the four cavities communicate in pairs with the original cavity of the ectodermic vesicle. This latter space remains small, and has been named the common amniotic cavity.

From these facts it is concluded that polyembryony in the armadillo is the result of a precocious budding, which apparently can not be correlated with the formation of the blastomeres of the four-celled stage.

Factors Controlling the Rate of Regeneration in the Frog Tadpole: C. ZELNY, University of Illinois.

(1) *Spermatogenesis in the Gryllidæ.* (2) *The Puget Sound Marine Station:* W. J. BAUMGARTNER, University of Kansas.

(1) The germ cells of the male cricket show division figures which do not bear much resemblance to the illustrations shown by Vom Roth. There is no circle of four balls as he shows them, although he is correct in interpreting the tetrad as dividing longitudinally and transversely. The number of chromosomes is 23 and is reduced to 12 and never to 6 as Vom Roth has it.

One other important observation was made. One of the tetrads divides *unequally in the first division and the larger half always goes with the*

prominent accessory. This means that the accessory does not bear all the material which differentiates sex. It may further indicate that a second accessory chromosome is in the process of formation.

(2) The Puget Sound Marine Station was started as a seaside summer school of biology by the Washington State University. Later the other institutions of the state joined in the endeavor. In 1910 the educational institutions of other states were asked to cooperate in the work of the station. At present the following states have some of their institutions participating: Washington, Oregon, Idaho, Nebraska and Kansas. There is now provided a good laboratory, furnished with running fresh and salt water and electric lights. A large dining hall and 50 walled tents provide the living quarters. A dredge boat and many small boats with nets give abundant means for visiting the various islands and collecting the desired material. The climate is dry, cool and pleasant for summer work. But the station's greatest attraction is the almost inexhaustible supply of animal and plant life. The number and variety of species is unusually great and the numbers of many species are countless. (One hundred and ten slides, made from photographs of the animals, were shown, giving a glimpse of the life of the islands of Puget Sound.)

Observations on Protozoan Fauna of High Mountain Lakes of Colorado: C. H. EDMONDSON, Washburn College.

During July and August, 1911, twenty-one lakes, situated along the Colorado divide in Boulder, Grand, Gilpin and Clear Creek counties were visited and collections made from them with a view of studying the protozoan fauna of high altitudes.

Of these twenty-one lakes, eighteen are 10,000 feet or more in altitude, the highest being Summit Lake, 12,740 feet elevation. Collections were made on James Peak at 12,500 feet and on Mt. Evans at 13,000 feet.

Silver Lake and Lake Eldora were sounded and dredged for bottom fauna.

The lakes are shallow, Silver Lake, at its present height, is about fifty feet in depth; Lake Eldora about forty feet in depth.

During the summer the temperature of these high lakes ranges from 40 degrees to 50 degrees F.

Two species of *Diffugia*, found among others in the bottom of Lake Eldora, *Diffugia lebes* Penard and *Diffugia ourvicaulis* Penard, are characteristic species of the deep lakes of Switzerland. Dr.

Penard has suggested that species common to the deep Swiss lakes and high elevations where conditions resulting from glaciers exist may represent a remnant of a glacial protozoan fauna.

Of the altitudinal range of the species observed the following is a summary:

Ciliates—over 11,500 feet altitude . . . 23 species.
Ciliates—over 12,000 feet altitude . . . 9 species.
Flagellates—over 11,500 feet altitude . 13 species.
Flagellates—over 12,000 feet altitude . 2 species.
Sarcodina—over 11,500 feet altitude . . 54 species.
Sarcodina—over 12,000 feet altitude . . 39 species.
Sarcodina—at 13,000 feet altitude . . . 2 species.

The great altitudinal, as well as latitudinal range, of some of our common species of protozoa is shown by the fact that twenty-nine of the species found in the high lakes of Colorado have been reported from sea level in the oceanic island of Tahiti in the southern hemisphere. A classified list of protozoa of the lakes of Colorado will appear in the University of Colorado Studies.

The Cerebrum of Necturus and the Problem of the Evolution of the Cortex: C. T. HERRICK, University of Chicago.

The Asymmetrical Distribution of the Polian Vesicles and their Correlation with the Retractor Muscles of Thyone: J. W. SCOTT, Kansas State Agricultural College.

As is well known, echinoderms have remarkable powers of regeneration. Under certain conditions *Thyone* eviscerates itself, throwing off the tentacles, esophagus, stomach, intestine, the calcareous ring, the ring canal with attached polian vesicles, the nerve ring, and the muscles which retract the esophageal ring. It was found that regeneration of all lost parts takes place after evisceration. However, to determine this fact it was necessary to study individual differences. For example, the number of polian vesicles varies from one to four, usually one, commonly two, occasionally three, rarely four. Both in size and number the polian vesicles show a strong tendency to occur on the left side. This asymmetrical distribution does not appear to have any present functional significance, and so must be referred to ancestral conditions. The additional fact was brought out that the number of retractor muscles varies with the number of polian vesicles. The average number of retractor muscles per individual increases as the number of polian vesicles increases; this is true in particular for the left side. Even after regeneration the same correlation holds true. The original asymmetry of each individual was re-

stored in all except one case; in this animal there was a change from single to multiple parts which included both polian vesicles and retractor muscles.

A full account with discussion of these results will be given in the *Journal of Experimental Zoology*.

The Distribution of North American Earthworms:

F. SMITH, University of Illinois.

In North America north of Mexico, scarcely fifty species of earthworms are known, which is less than five per cent. of the known species of the world. This small number is due in part to lack of study, but also to an actual lack of the variety usually found in territories of similar extent.

The genus *Diplocardia* is very characteristic of the region and includes species from Illinois, Nebraska, North Carolina, Georgia, Florida and Mexico. Other parts of the United States east of the Rocky Mountains doubtless have species. *Diplocardia* is a very primitive type of the family Megascolecidae and probably originated in North America as early as the Jurassic.

West of the Rocky Mountains are found a few species of *Plutellus* and *Megascolides*, of which genera the remaining species are found in Australia and India. These are primitive forms of Megascolecidae which presumably originated in Australia and representatives migrated from there during the Jurassic and Cretaceous by way of Siberia and Alaska into the Pacific region of North America.

The family Glossoscolecidae is represented by the primitive aquatic genus *Sparganophilus*, of which species are known from Florida, the Mississippi Valley, California and Mexico. This genus probably originated on this continent as early as the late Jurassic.

The family Lumbricidae includes the majority of the North American earthworm species. The most of them are also known in the Eurasian region, where they probably originated. The few endemic Lumbricid species of the United States are found chiefly in the states of the Atlantic region.

A few peregrine species of the Megascolecidae genera *Microscolex* and *Pontodrilus* are found in the coastal regions.

Probably few if any species will be found endemic in the glaciated parts of the continent.

Studies upon the Migratory Movements of the Pacific Coast Lobster: BENNETT M. ALLEN, University of Wisconsin.

Brass tags were affixed to 346 specimens of *Panulirus interruptus*, that were released at different times, at Santa Barbara, California, also at various points on the coasts of Santa Cruz and Anacapa Islands.

In all, 26 were caught and reported by the fishermen. The greatest distance traversed was 9½ miles in 28 days. The most rapid average rate of migration was .43 mile per day in the case of a specimen that traveled six miles in fourteen days. Eleven traveled less than one mile in an average of eighteen days. Eight traveled more than one mile in an average of twenty-seven days. The total average of distances traveled was 1½ miles in an average time of twenty-two days. The movements were haphazard.

Of the twenty-six caught, most of which were again released according to request, 5 were caught again—a third time in all. This investigation was financed by the Californian Fish and Game Commission.

The Chiasma of the Trochlearis Nerve: H. V. NEAL, Knox College.

The Habits of Fiddler-crabs: A. S. PEARSE, St. Louis University.

(To appear in the *Philippine Journal of Science*.)

Some Glimpses of Biological Conditions in Western Nebraska: R. H. WOLCOTT, Nebraska University.

(1) *Notes on the Rate of Growth of Freshwater Mussels.* (2) *The Fairport Biological Station:* R. E. COKER, Bureau of Fisheries.

(1) *Karyosomes in the Ova of Passer domesticus.* (2) *Magnetic Control of the Movements of Paramæcia which have Ingested Iron:* E. H. HARPER, Northwestern University.

(1) In the ovary of the sparrow in the winter the nuclei, particularly of the smaller ova, show an aggregation of the chromatin into karyosomes and absence of the chromatin net. These bodies have so definite an appearance as to suggest the possibility of definiteness in number. The count showed the probable number to be twenty-two, harmonizing with known results from the spermatogenesis which indicate the haploid number of chromosomes as eleven. On this basis, these bodies in the ova may be called the prochromosomes. Stages in the breakdown of the nucleoli to form the chromatin net were also shown.

(2) The question is raised whether the normal position of stable equilibrium with antero-posterior

axis vertical may have a directive influence in the negative geotaxis of these animals.

Paramœcium in its ordinary movements overcomes the effect of the slight difference of specific gravity that may exist between its ends, but as the negative geotropism is a delicate reaction elicited best in the absence of other stimuli it is possible that it may be a passive orientation due to a tendency of quietly swimming animals to fall into a direction affording stable equilibrium.

The specific gravity factor may be accentuated by ingestion of iron which lodges at first in the posterior end. In a control experiment with an electro-magnet acting at right angles to gravity overweighted animals which normally aggregate at the bottom are brought into circulation, swimming upward in the strong magnetic field, past the pole of the magnet and dispersing at some point above, causing a counter circulation to the bottom in the weaker portion of the field.

In such experiments with overweighted animals we have an example of obedience to the passive orienting tendency in the region where they are buoyed up by the magnet and of resistance to it in the region where they are not so supported. Internal stimuli induced by fatigue from swimming upward cause the change to the downward path. The downward movement may be broken up by recurring compensatory movements to make up for any passive deflections brought about by the action of gravity. In the upward movement, on the other hand, there is unbroken continuity unless interrupted by extraneous causes. It may be called a passive or mechanical tropism.

(To appear in the May number of the *Journal of Animal Behavior*.)

The Land Planarians of North America, with a Note on a New Species: L. B. WALTON, Kenyon College.

Since calling attention to the rediscovery of *Rhynchodemus sylvaticus* described by Leidy in 1851¹ the species has been found in abundance not only in Gambier but also at Urbana, O., and Meadville, Pa. The material from which the species was originally described was placed at the disposal of Girard by Leidy for study in connection with the former's paper on the planarians of North America.² Inasmuch as the specimens were in the possession of Girard at the time of the death of Leidy³ and were given him for use as he deemed

best, it is quite probable they are in the possession of some of the European museums, if in existence. Thus far it has been impossible to locate them, however.

Two specimens of a much larger species approximating 20 mm. in length and uniformly dark blue in color have also been taken in Gambier. For this the name *Rhynchodemus atrocyaneus* is proposed.

The land planarians of North America and the adjacent islands may be tabulated as follows: *Geoplana nigrofusca* (Darwin), Mexico and South America (common). *Geoplana stollii* Graff, Guatemala (a single specimen known). *Placoccephalus kewense* (Mosley), cosmopolitan in hothouses, original habitat unknown (common). *Rhynchodemus sylvaticus* Leidy, East. U. S. (common). *Rhynchodemus atrocyaneus* Walton, Ohio, central U. S. (?) (two specimens known). *Amblyplana cockerelli* Graff, Jamaica (a single representative).

Land planarians occur under slightly decayed pieces of board, sticks, etc., particularly in grassy plots of old orchards, or lawns, usually in association with snails, the young of which they superficially resemble. The anatomical structure of the Ohio forms is being studied.

(1) *The Sense of Taste in Birds.* (2) *The Breeding Behavior of the Herring Gull:* R. M. STRONG, The University of Chicago.

(1) Chicks, doves, ducks and gulls were studied. The methods employed involved soaking the food which was given to the birds in various solutions. Chicks and ducks showed a dislike for food which had been treated with weak acids, sweets, table-salt and bitters. Quantitative experiments have been conducted for several months with gulls kept in captivity. These birds show a dislike for sour and salty solutions even when they are weak to the taste of the experimenter. The work with sweets and bitters is not yet finished for the gulls.

(To be published elsewhere.)

(2) Studies were made of the breeding behavior of the herring gull from the standpoint of modifiability, and especial attention was given to the voice of this bird. The report was illustrated by lantern slides.

(To be published elsewhere.)

CHANCE AND THE PREPARED MIND¹

("In the fields of observation chance favors only the mind which is prepared."—Pasteur.)

It was at the opening of the Faculté des Sciences at Lille on December 7, 1854, that Pasteur, only thirty-two years of age at the time, but already professor and dean of the faculty, uttered these words in upholding, in his inaugural address, the value, on the one hand, of practical laboratory instruction as an aid to the solution of industrial problems, and on the other the importance of investigation in pure science, even though the resulting discoveries might have no immediate application. The point of view may have been novel when it was uttered, but in the sixty years that have elapsed how familiar it has become. How closely it approximates the ideals of those who are striving to improve the conditions of medical education and of medical research in our own day and country. What better argument can the most ardent advocate of detailed practical instruction in laboratory or hospital (medical training at first hand) present, than that which Pasteur offered in 1854. He asks:

Where will you find a young man whose curiosity and interest will not immediately be awakened when you put into his hands a potato, when with that potato he may produce sugar, with that sugar, alcohol, with that alcohol, æther and vinegar? Where is he that will not be happy to tell his family in the evening that he has just been working out an electric telegraph? And, gentlemen, be convinced of this, such studies are seldom if ever

¹ An address on medical education, by Richard M. Pearce, M.D., University of Pennsylvania, delivered at Syracuse University, May 21, 1912, under the auspices of the Alpha Omega Alpha Honorary Medical Fraternity.

forgotten. It is somewhat as if geography were to be taught by traveling; such geography is remembered because one has seen the places. In the same way your sons will not forget what the air we breathe contains when they have once analyzed it, when in their hands and under their eyes the admirable properties of its elements have been resolved.*

Pasteur was a chemist, a physical chemist, if you will, and his illustrations were drawn from the realms of physics and chemistry, but if one substitutes for "electric telegraph" any piece of apparatus now in use in a medical laboratory or a hospital, the principle of the better type of modern medical instruction is embodied in his argument. He was talking to those who, after two years of practical and theoretical study, were to enter industrial careers as overseers and foremen in factories, foundries and distilleries. But neither time nor circumstance fundamentally alters the applicableness of his observations. After sixty years we may still urge his thought as the soundest of principles in the better education of men and women who are ultimately intended to enter careers as our overseers in matters of health and disease and as the foremen of public hygiene. Have our present-day medical schools succeeded in bringing to the training of their students the same practical and scientific thoroughness which Pasteur demanded for students in the industrial sciences and which students of the latter sciences now procure? If not, where lies the fault; in the college or the medical school, in the state or the public? Or are all more or less to blame? These questions will be discussed in due time, but first, let us turn to Pasteur's other proposition, investigation for its own sake. After stating his wish to be directly useful, personally and through

his laboratory, to the industries of Lille, he says:

Without theory, practise is but routine born of habit. Theory alone can bring forth and develop the spirit of invention. It is to you specially that it will belong not to share the opinion of those narrow minds who disdain everything in science which has not immediate application. You know Franklin's charming saying! He was witnessing the first demonstration of a purely scientific discovery, and people round him said: "But what is the use of it?" Franklin answered them: "What is the use of a new-born child?"

Do you know when this electric telegraph, one of the most marvelous applications of modern science, first saw the light? It was in the memorable year 1822; Oersted, a Danish physicist, held in his hands a piece of copper wire, joined by its extremities to the two poles of a Volta pile. On his table was a magnetized needle on its pivot, and he suddenly saw (by chance you will say, but chance favors only the mind which is prepared) the needle move and take up a position quite different from the one assigned to it by terrestrial magnetism. A wire carrying an electric current deviated a magnetized needle from its position! That, gentlemen, was the birth of the modern telegraph. Franklin's interlocutor might well have said when the needle moved "But what is the use of that?" And yet that discovery was barely twenty years old when it produced by its application the almost supernatural effects of the electric telegraph!

This, gentlemen, may seem trite to you, for it is an argument oft repeated, but its significance, as far as medicine is concerned, lies in the fact that at the time Pasteur made these statements modern medical investigation was just beginning. The celebrated physiological institute at Berlin had been in existence only sixteen years; Schwann, following Schleiden, had elaborated the cell doctrine only fifteen years before and anesthesia had been practised for only six years. Claude Bernard was in the midst (1850-60) of his important discoveries concerning the pancreatic juice, the glycogenic function of the liver and the vasomotor system; three years were

* Vallery-Radot, "The Life of Pasteur," McClure, Phillips & Co., New York, 1902.

to pass before Virchow established (1855) the first pathological institute and as many again before this great master was to announce the doctrine of cellular pathology; and finally, it was thirteen years before Lister's first publication concerning the antiseptic treatment of wounds.

In all these activities and those which followed, the ideal of seeking for the truth no matter where it might lead—the ideal of pure science—was the secret of that wonderful progress which medicine has made in the last seventy-five years.

Now, however, it is time to return to our text, "In the fields of observation, chance favors only the mind which is prepared." What did Pasteur mean by "chance"? His meaning is very evident in his example of Oersted and the magnetized needle. The mind which is trained to observe the details of natural phenomena, and to reason concerning the bearing of known laws on such phenomena, is the "prepared mind," that is to say, it is a class of mind which, because it is endowed with a peculiar faculty, best described as scientific imagination—grasps the significance of a new observation, or of a variation from a known sequence of events, and thus establishes a new law or invents a new practical procedure. To no man perhaps is this adage of Pasteur more applicable than to himself. It was his work in chemistry and his studies in crystallography that gave him the "prepared mind" which correctly interpreted the significance of the chance observation that the presence of a vegetable mould, the *Penicillium glaucum*, in solutions of salts of the tartaric acids, changed an optically inactive to an optically active fluid. He grasped at once the true interpretation of this reaction. The disappearance of the dextro-tartaric acid, the permanence of the levo-tartaric acid, could be explained only by the assumption that the ferments of this particular fermentation "feed more readily

on the right than on the left molecules." So did "chance" direct the "prepared mind" to those fundamental observations which established our present-day principles of fermentation, and which, as the result of work on alcoholic, acetic, lactic and butyric fermentation, led to Pasteur's final dictum:

The chemical act of fermentation is essentially a correlative phenomenon of a vital act beginning and ending with it.

It was but a short step for the mind thoroughly familiar with the principles of fermentation to embrace the opportunity offered by the study of the etiology of the infectious diseases, and so through all his work, as that in connection with the silk-worm problem, vaccination against chicken cholera and anthrax and the treatment of rabies, the "prepared mind" of the great master saw and appreciated the significance of every observation and every opportunity which presented itself.

Many other examples might be presented, as Semmelweis and his observations on the high mortality from puerperal sepsis among those under the care of students fresh from the dissecting and autopsy room and the low mortality among patients under other supervision. So also Lister and his anti-sepsis; and best of all, perhaps, for purposes of illustration, the sequence of Ehrlich's discoveries. We are told that in his student days Ehrlich was interested above all other things in the study of chemical affinities and worked incessantly with the new anilin dyes. Indeed the story goes that so engrossed was Ehrlich in his work that neglect of the required studies gave rise to some question concerning his right to receive his degree. The situation as described by Christian A. Herter³ was as follows:

³Herter, C. A., "Imagination and Idealism in the Medical Sciences," *Jour. Am. Med. Assn.*, LIV, p. 423, 1910.

Although at this time Ehrlich was especially under the direction of the anatomist Waldeyer, he rapidly developed a capacity for chemistry which was a surprise both to himself and to the chemist, Adolf von Baeyer, whose lectures had been systematically cut by the gifted but unconventional student. For unconventional he then was, and ever has been, neglecting what he did not like and throwing himself with fervor and intense energy into the solution of the themes that attracted him. From the outset it was clear that Ehrlich would make a career as an experimental investigator. Much of the time he was supposed to spend in taking the usual medical courses he devoted to experiment. When Robert Koch was shown through the laboratory at Breslau by one of the professors, his attention was called to a young student working at a desk covered with bottles of dyestuffs. "There is our little Ehrlich," said the professor; "he is a first-rate stainer of tissues, but he will never pass his examinations." The prediction about the examinations came perilously near fulfillment; Ehrlich made bad flunks and it is hinted that he never would have received his degree had he not made a discovery—namely, the existence of the peculiar type of leucocyte which is known to us as the "plasma-cell." The faculty reasoned that it would be improper to keep so promising and original a worker indefinitely in an undergraduate position, and it is suspected that they mitigated the rigor of the examinations in order to relieve their own embarrassment.

These early studies were doubtless responsible for what must be considered as the main theme of all Ehrlich's work—the specific affinity which exists between specific living cells and specific chemical substances. The "prepared mind" is evident in his study of the cells of the blood, of the selective action of methylene blue on the nervous system, of the use of the same dye in the study of oxidation and reductions occurring in tissues, of his studies in immunity, of the specific treatment of protozoan disease, and also according to recent reports in his application of the same principle to the study of cancer. Manson's studies of the relation of the mosquito to filariasis, which led to Ross's study of the transmission of malaria by the same insect,

is another example of the "prepared mind" properly interpreting a chance observation. Sometimes such discoveries are referred to as the result of scientific imagination—and it truly is this—but doubtless the same "chance" came to many besides Pasteur, Ehrlich, Laveran, Koch, Theobald Smith, Manson, Ross and Reed; it was the training of these individuals, the mind prepared to utilize scientific imagination, that enabled them to grasp the opportunity offered by "chance" observation. Every one familiar with the history of investigation in medicine knows that before Harvey, men studied the circulation; that before Pasteur, bacteria were seen in diseased conditions; before Lister, the effect of cleanliness upon surgical mortality had been noticed; before Laveran, the plasmodium of malaria had been seen; before Manson and Ross, the possibility of the transmission of malaria by the mosquito had been discussed. Truly, remarkable achievements are never unique occurrences in nature. Even the greatest men rest on the shoulders of a large multitude of smaller ones who have preceded them, and epochal discoveries emerge out of a period of intellectual restlessness that affects many minds.*

But of these minds, it is that one which is "prepared," trained in the methods of observation, therefore possessing the priceless quality of scientific imagination, which sees the proper block which when placed exactly where it belongs completes the edifice of a perfect theory, and thus establishes a new landmark for future progress.

But what, you ask, has all this to do with the training of the physician? How does it apply to medical education? We admit the value of these qualities in the investigator, but of what value are they to the man seeking the education necessary to

* Flexner, S., "The Biological Basis of Specific Therapy," Ether Day address at the Massachusetts General Hospital, October 16, 1911.

practise medicine? Let me repeat Pasteur's adage—"In the fields of observation, chance favors only the mind which is prepared." Certainly all will agree that medicine is largely an observational science and one of the "fields of observation" of Pasteur's definition. Medicine may not be all science, but clinical medicine in its most essential phase—diagnosis—is essentially a science of observation, either of direct observation by the use of the unaided senses or indirect by the use of instruments of precision, or by chemical, biological or other tests. Therefore, whatever force or whatever lesson this adage may carry, applies to medicine. And now as to the interpretation of "chance." I have not been able to obtain the original French of Pasteur, but from his parenthetical phrase in connection with the discussion of the telegraph it is clear that he meant exactly what the translator has given us, chance or opportunity in the sense of an unexpected observation or an accidental occurrence. Pasteur's idea was that such unexpected or accidental occurrences would not arrest the attention of the poorly prepared mind, but that the well-prepared mind, trained to observe, to think and to compare, would grasp the significance of the unexpected, the unusual or occasional, put the observation to the test, by experiment or control, and arrive at the correct conclusion. Is not this a matter of daily occurrence in clinical medicine? Does not chance (opportunity some would call it) and care in details play an important part in diagnosis? Is not every ailment the physician sees a puzzle; every diagnosis, if correct, a solution of that puzzle? One speaks of the man who solves the puzzle which has baffled half a dozen other men, as a keen or accurate diagnostician. They imply that he has an added power, or that his skill is the result of wider experience, forgetting they may

have seen as many individuals with the malady as had the consultant, and perhaps totally ignorant of the fact that his diagnosis was possibly based on a chance observation which meant more to his trained imagination than it did to minds unaccustomed to weigh the significance of details. Every clinician of experience can give examples of the importance of chance and imagination in actual diagnosis. An interesting illustration is that

of the two students who reported on the same patient in competition for a clinical prize. The patient presented, among other symptoms, a remarkable discoloration of a certain area of skin, and the first student described this discoloration with the most careful minuteness. He measured it in different directions and drew a rough sketch of its general outline. The second observed the phenomenon with equal care, but he exercised his imagination and formed a hypothesis which he proceeded to put to the test. He asked a nurse for a wet towel, with which he wiped the discoloration away. It is evident that the faculty which he thus brought to bear on the problem before him would be likely to stand him in good stead in relation to many others of a more complicated character; and that his exercise of the art of diagnosis would be practically immune from the errors incidental to the habit of taking all appearances at their face value. Imagination at once points to the possibility of more than one explanation of any given occurrence, or alleged occurrence, and compels inquiry as to the existence of probable causes beyond the particular one which may at first sight appear to have been in operation.⁵

From what has been said, then, it should be evident that it is the first duty of a medical school to prepare men properly for the practise of medicine (and the most ardent advocate of research in the university will not deny that this is the first duty). If so, what are, conditions to be fulfilled to ensure the "prepared mind" of Pasteur's adage?

The Preliminary Education of the indi-

⁵"Imagination in Medical Research," *Lancet*, 1912, CLXXXII., 179.

vidual is the first and in many ways the most important consideration. I know it is bringing coals to Newcastle to discuss this question before the students and faculty of Syracuse University, for you have been among the first to recognize the value of two years' college work which shall include physics, chemistry and biology. Still this principle is not generally recognized. Many of those in positions of authority in our medical schools, while loudly proclaiming the right of medicine to a place among the sciences and indeed characterizing it as the "Mother of the Sciences," deny that a scientific education is a prerequisite to medicine. True, the opposition is frequently due to a realization of the awkward financial position in which an administration might be placed if students' fees diminished. Frequently also it is due to the claims of those who hold that a greater cultural value lies in following the humanistic rather than the scientific school of thought. Naturally, there is also the "poor boy cry" and the closely associated cry that outlying districts will not be properly cared for if the cost of medical education is increased. The "poor boy" argument may be dismissed at once, for those who have had experience in teaching medicine know that the boy, poor or otherwise, who knows what he wants in the way of an education, gets that education in spite of all difficulties, and as a rule, if he has to work for it, is keen enough to get the best that is to be had. Such men will "come through" despite all apparent barriers in the way of higher preliminary requirements; if the indifferent "poor boy" fails, lacking ambition and a clear conception of what he wants, so much in favor of the higher requirements.

As to the outlying districts, we need have no fear as long as the ratio of physicians to

population is 1 to 568⁶ and the use of the automobile is increasing. If the ratio should change greatly, which does not seem likely, for only two states⁷ (North and South Carolina) have a ratio of less than 1 to 1000, the matter then becomes one for state regulation, for, as the report of the Carnegie Foundation has shown, we have enough physicians, but the difficulty lies in the tendency of physicians to seek the larger civic centers.

With the discussion of the cultural value of humanistic as compared with scientific studies, we are not concerned. It is sufficient that in a university medical school a man can not properly study modern medicine without that knowledge which comes from a familiarity with laboratory work in physics, chemistry and biology. The value of biological training for those interested in practical medicine was emphasized by Huxley many years ago, and that in physics and chemistry has recently been emphasized by Friedrich Müller⁸ in describing, for the benefit of the English Commission, the training of the German medical student.

During his first and second year,⁹ the medical student attends lectures and does laboratory work in physics, chemistry, botany and zoology in the philosophical faculty, and he has the opportunity of widening his views by listening to lectures on philosophical or historical subjects. His teachers and laboratories are the same as for the students of the natural sciences, and this is right, because there is no such thing as special medical physics

⁶ Flexner, A., "Medical Education in the United States and Canada," Bull. No. 4 of the Carnegie Foundation for the Advancement of Teaching, 1910.

⁷ *American Medical Association Bulletin*, 1910, V., 278.

⁸ Müller, F., "Memorandum on Medical Education Submitted to the Royal Commission on University Education in London."

⁹ The German student seldom takes his state examination until the end of five and a half years' work (Müller).

or chemistry; the physician requires a broad knowledge of the general sciences of physics and chemistry.

It is most important to have this statement of Müller's at a time when an effort is being made to place physics, chemistry and biology in the medical curriculum. With or without a fifth year it is a dangerous policy. The experience of one school in this regard is enlightening. During the period of change from a high school to a two-year college requirement, conditioned men were cared for by allowing time in the first half of the first year to make up conditions. The procedure took eighteen hours a week from the time which should have been devoted to purely medical studies. In such an emergency as that of a change of policy, this was perhaps justifiable, but what university school with a four-year course can afford this arrangement as a permanent policy? And if we are to have a fifth year, progress demands that it should be a clinical or hospital year, and not a preliminary year for work which belongs to the college. The modern curriculum of a first-grade medical school demands a student's full time and attention and no amount of general culture can make up for absence of prerequisites in physics, chemistry and biology. The school which allows mixed requirements, or low requirements or conditions does so at the expense of efficiency; the good men suffer on account of the slow progress of the poorly trained; the inefficiency of the teaching under such circumstances becomes noised about, and it comes to pass that the best-trained men go to schools which take only their kind, and thus eventually low standards react on the school allowing them.

But this is not all. Another factor, the state, is beginning to play an important part in determining the conditions pre-

requisite to medical education. Five¹⁰ states have passed laws demanding that for license to practise medicine an applicant must have had two years of college work as a minimum requirement, and four¹¹ demand one year. This, we must admit, is only the beginning. As state after state adopts the same ruling, schools not demanding such preparatory study must see the territory open to their graduates (and therefore the territory from which they draw students) gradually narrowed. Certainly, to-day, no school, and certainly no university school, can face with equanimity, this discrimination; and "disappointed indeed will be that student who, after having spent a large amount of time and money, finds on graduation that his diploma is not recognized in a large number of states."¹²

Methods of Teaching.—Within the medical school itself the matter of educational policy is clear. Here there can be only one procedure, the constant and consistent employment of the "do it yourself" or "learn by doing" method; the student must be taught to observe, experiment, reason and act for himself. This, I know, is trite, but the conditions out of which our present methods of medical education have emerged demand that this point of view be continually emphasized. It is not long since the day of the two- and three-year course and the imparting to undergraduates of all medical instruction, outside of anatomy and inorganic chemistry, by lecture. The development of the laboratory branches, histology, pathology, bacteriology, physiological chemistry and pharmacology—and the cheapening of physiological apparatus

¹⁰ Colorado, Indiana, Iowa, Minnesota and North Dakota.

¹¹ Connecticut, Kansas, South Dakota and Utah.

¹² *Jour. Am. Med. Assn.*, LVII., p. 1138, 1911; LVIII., p. 487, 1912.

—have given a new turn to medical teaching, that of active participation by the student. But still even in these branches the lecture still persists in most schools and frequently is so magnified in connection with the laboratory instruction as to make it appear in the eyes of the student as the most essential part of the course. The advance in methods and means of practical laboratory instruction—that is, the visible machinery for developing the principle of teaching by actual observation and experiment—would seem in some schools to be an equipment for advertising purposes only. One does not have to go outside the group of our so-called “big” schools to find a department of pathology, abundantly equipped with apparatus and a wealth of pathologic material, offering five lectures a week; and one may find an elaborately equipped student’s laboratory of physiology manned by assistants while the head of the department fulfills his duty to his class with three or four lectures a week; and likewise, in the clinical branches, few men have had the courage to do away with frequent and voluminous lectures. Even schools controlling a large hospital, and sometimes several, and thus having an abundance of clinical material, do the bulk of their teaching by the formal lecture and the amphitheater clinic. The ward class and the clinical clerk system gain ground but slowly. The reason for this attitude is easily found. The lecture is the easiest form of teaching, and the average teacher, whether he be the laboratory man overburdened by executive detail and handicapped by lack of assistants, or the clinical teacher limited in time by a busy practise, follows the lines of least resistance, forgetful, though sometimes resentfully so, of the best needs of his class. Usually coexistent with a pernicious lecture system is the habit of leaving those most favorable fields

for proper education—the laboratory exercise and the ward or dispensary class—to assistants. No one has less desire to belittle the work of assistants or to lessen their independence than have I, but in the department in which the head lectures only the student naturally assumes that the work of subordinates—in laboratory or clinic—must be work of subordinate importance, and thereby he comes to have a wrong estimate of the live part of his education. The most ardent supporter of the lecture system can not say that he always holds the interest of his class. He may hold their attention and be flattered by copious note-taking, but this has for its object only one purpose—the final examination. The real education—the training which means power and which characterizes “the mind which is prepared”—can come only through independent but wisely directed observation, experiment and reasoning on the part of the student.

I have discussed elsewhere¹³ how the latter system may be fostered, and am now glad to be able to reinforce my position by quoting from the recent very excellent address on this subject by Professor G. M. Jackson.¹⁴ As to the share of the teacher Professor Jackson says:

It is evident that each teacher must understand the curriculum as a whole. The laboratory man must be familiar with the clinical work. But this is not all. Since good teaching must take into account that which has gone before as well as that which is to follow, it is equally evident that the clinical man must be familiar with laboratory subjects and methods. We can not expect the best results in medical education until there is a better understanding and more cooperation between teachers of the various subjects all along the line.

¹³ Pearce, R. M., “The Experimental Method: Its Influence on the Teaching of Medicine,” *Jour. Am. Med. Assn.*, LVII., p. 1017, 1911.

¹⁴ Jackson, G. M., “On the Improvement of Medical Teaching,” *SCIENCE*, XXXV., p. 566, 1912.

As medicine progresses, all phases appear more clearly as varied manifestations of the same underlying biological science, and only when this is realized will the clinical and laboratory work be more closely knitted together.

As for the student, it is suggested that he work out everything for himself by the method of discovery. This applies not only to the original observations, but also to the latter process of reasoning, whereby we proceed from particular data to general conclusions, and thence to rational action. The method of self-activity may therefore be expressed in a negative way by the following practical rules: Never tell a student anything he can observe for himself; never draw a conclusion or solve a problem which he can be led to reason out for himself; and never do anything for him that he can do for himself.

There are, of course, limitations to the application of this method, as lack of time, an overcrowded curriculum, inability on the part of the teacher to fully grasp the situation, and failure to always maintain sustained effort on the part of the student, but its value over the lecture system is so great that it should be followed in "so far as practicable" (Jackson) and should be supplemented by demonstrations and conferences or recitations rather than by lectures, if one truly seeks to prepare properly for the practise of medicine.

Influence of the Spirit of Investigation.
—But aside from this training the university has another duty to the prospective practitioner of medicine. This is its duty in the encouragement of investigation, which is indeed a double duty, a duty to its students and a duty to the community it serves.

The question of allowing undergraduates to undertake independent original investigation is, I know, a debatable one. Certainly in most schools our overcrowded curriculum renders such work impossible unless a wise arrangement allows elective studies, as at Harvard in the fourth year, or as at Johns Hopkins in each year. My

remarks on this subject are therefore based on the assumption that an elective system is possible in every school.

As every teacher knows, each class contains a considerable number of men who desire to pursue work, to a greater extent than the conventional course allows, on certain subjects or by special methods, or less frequently, perhaps, they desire, and are usually well qualified to undertake, minor investigative work. To the former, as well as to the latter, any effort spent in work beyond that given the entire class becomes, necessarily, for them, the acquirement of the methods of research and as this means a knowledge of the exact, painstaking methods by which the realms of the unknown are explored, it is an exercise which prepares the student for the daily routine research work of the physician who truly practises his profession. As a training for future work, its value is definitely known and the increased zest and enthusiasm exhibited toward their medical work by men who have had this opportunity are always evident. Pedagogically, therefore, it would seem advisable that every student should have the opportunity for minor investigative effort, in order that he may become acquainted at first hand with the careful methods of experimental medicine. The bearing of the tangible results of his work on the subject investigated is a matter of little or no importance; the vital thing is the increased power which he himself acquires.

There is another way in which the encouragement of research aids the student, but which is possible only to those schools following the wise policy of appointing to professorial chairs, teachers who are likewise investigators. The influence of such teachers in the development of independent and resourceful practitioners is the secret of the great success of our better schools.

The correctness of this statement may be easily demonstrated.

If one examines courses in the same subject in a number of schools it is found that those which are best presented are under the control of men actively engaged in research work. Such men are alive to the advantages of new methods in their own subject and of new ways of applying old methods. Ever thinking and pondering about new methods of acquiring knowledge for themselves and their science, they appreciate better than does the non-investigator, that which will aid the student to acquire knowledge, and in their teaching they bring to bear on the problems which the student has to face the same methods of attack which they use in their own researches. On the other hand, one finds the men who never or only occasionally contribute to the literature of their science are the men who confine their teaching to perfunctory routine courses, with a profusion of lectures, and who never bring the spirit or methods of the investigator into their teaching. So, likewise, it is with the student taught under these two conditions. The student who knows that he is working in a department actively emphasizing new methods and striving to develop new truths, knows that his instruction is presented in the spirit of the department, and thus receives that stimulus and inspiration which insures his approaching clinical medicine with a proper appreciation of the scientific method. The student under the method of the non-investigator, on the contrary, has no incentive other than that of acquiring a knowledge sufficient to allow him to pass an examination.

An allied argument lies in the fact that the medical school that fosters research attracts the best-trained men as students. We have, as is well known to many of you, a medical school in this country which has,

for several years, arbitrarily selected from a large number of prospective matriculants the certain definite number which it desires; the rest, sometimes nearly fifty per cent. of those accepted, go elsewhere. Now this school has the highest requirements and perhaps the smallest alumni body of any prominent school in the country. It is not, therefore, a question of easy entrance or of the loyal influence of alumni, nor is it a question of better laboratory and hospital facilities, for other schools have equally good equipment in both respects. Likewise it is not a question of geographic location or center of population. The enviable position of this school is due solely to the policy of combining research with teaching and of appointing to its staff teachers who, with few exceptions, are also investigators.

As to the duty of the university to the community in the matter of research, there can be only one opinion. If the purpose of the machinery of medical education is to "bring healing to the nations," if the business of medicine is to "get people out of difficulties through the application of science and dexterity, manual and physical" (Cabot), then it is the duty of the university not only to teach known principles and methods, but to advance knowledge and methods by research.

It is futile to say that it is sufficient to teach and to utilize known methods of freeing people from difficulties, for the mere statement of such an attitude implies that an obligation exists to extend known methods, or to invent new ones, in the hope of overcoming difficulties acknowledged to be at present without remedy. The ethical force of this statement can not be denied. To teach a subject implies the attempt to diffuse the available knowledge of that particular subject matter among a number of people for their good, as well as for the good of the community in which they live

and work; equally true is it that such an attempt to teach available knowledge imposes upon the teacher the obligation to leave untried no means by which the knowledge of his subject may be increased. It is not the privilege of the teacher to leave this extension of knowledge to others. His profession of ability to teach a particular subject carries with it his obligation to the group or community he serves, of adding to his subject knowledge of which they may avail themselves. If this applies to the individual teacher, how much more forcibly does it apply to the university with its ever-widening community and ever-increasing interests?

On the other side of the question, the university should not forget that medical research tends to ameliorate social conditions by diminishing the causes of physical and mental ills. This ideal of medicine the university and its community should foster and develop, for it is one of the greatest influences in our modern conception of social service; an influence indeed which was back of all Pasteur's work, and which he expressed in the statement of his desire to contribute "in some manner to the progress and welfare of humanity."

But aside from this altruistic ideal, I hold that research in the medical school offers important practical advantages to the university and that these advantages should not be forgotten by university authorities, who pride themselves on applying business-like methods to the problems of education. A policy which attracts a better-trained class of students, which improves the character of the instruction, which stimulates the student to a better type of individual effort and which enhances the standing of the university in the community and the nation is a policy which can not be ignored by university president, trustees or faculty.

The Relation of the Hospital to Medical Teaching and Research.—That the laboratories of our better medical schools are fully equipped for the kind of instruction which I have outlined, and that many are already fostering the "do it yourself" principle and the spirit of investigation is well known. In the clinical years, on the other hand, the situation is not so satisfactory. Many a medical school while building and equipping modern laboratories has failed to care properly for its clinical teaching, and has continued to foster the amphitheater lecture. If the method of first-hand instruction, which I have outlined, is to be followed, then the hospital must become the laboratory of the clinical years and a school must own or absolutely control its hospital. This is necessary in order (1) that the heads of the clinical departments may have a continuous service under their immediate charge and to the conduct of which they may bring their own assistants; (2) that in connection with such service they may develop laboratories for teaching and research in addition to the usual clinical laboratory now used only for purposes of diagnosis; and (3) that resident physicians may be appointed for indefinite service in order that trained teachers and investigators in clinical medicine may be produced in the same way as trained teachers and investigators in the laboratory branches are now produced, and (4) that the head of the department may provide adequately for that intimate first-hand clinical instruction which can be secured only by placing the student in actual contact with the patient.

Some schools, as Pennsylvania, Hopkins and Jefferson, have already solved the problem by the establishment of their own hospitals. This is naturally the ideal course for all university schools and a future for which every school should plan. But in the absence of the possibility of im-

mediate consummation of such an ideal, results almost as satisfactory may be obtained by the actual affiliation of municipal or independent hospitals with the stronger medical schools. A hospital has as much to gain by this arrangement as has the medical school, for while the chief duty of the hospital must always be the care of the sick and injured, this duty, as well as its other functions—the instruction of men who are to practise medicine and the advancement of medical knowledge by research—is best served by placing the conduct of the hospital in the hands of men highly trained in the methods of scientific medicine.¹⁵ This would not only enable the hospitals

to fulfill a greater function in the development of thoroughly qualified physicians, but it would also be best for the patients, since they would have the benefit of the best methods of treatment under recognized experts. A campaign of education should be carried on to show our municipal authorities that the hospital will be the best conducted in the interests of its patients and the community at large, if at the same time it is fulfilling its function as a great center of clinical teaching and research.¹⁶

Many examples may be presented of the ideal association of charity, teaching and research as the results of such affiliation; the most striking perhaps being the magnificent clinic of Müller in Munich and the clinics of the University of Leipzig. Here, as in many other continental cities and in England, the university authorities by agreement with the municipal authorities appoint the heads of the hospital clinics. The long continuance of this arrangement and the great fame of most of these

¹⁵ For a discussion of the advantages to be gained by the hospital, see Welch, W. H., "Advantages to a Charitable Hospital of Affiliation with a University Medical School," *The Survey*, XXVII., p. 1766, 1912.

¹⁶ Bevan, A. D., "The Modern Medical School," *Jour. Am. Med. Assn.*, LVIII., p. 652, 1912.

clinics is sufficient proof that both municipal authorities and university authorities find it mutually advantageous.

We should bring about the same state of affairs in this country and, in fact, a start has already been made. At Cincinnati the large municipal hospital has been placed in charge of the clinical teachers of the University of Cincinnati; in St. Louis, the Washington University has made a close affiliation with the new Barnes Hospital; in Boston, Harvard has made an affiliation with the Peter Brigham and several other special hospitals; in New York, Columbia University and the Presbyterian Hospital have established similar relations; in Cleveland, Western Reserve University has formed a combination with the Lakeside Hospital; in Chicago, Rush Medical College has had for a number of years the medical control of the Presbyterian Hospital, and recently has made similar contracts and arrangements with the Children's Memorial Hospital, the Home for Destitute Crippled Children and the Hospital for Infectious Diseases.—Bevan.¹⁷

How much better such an arrangement would be than that which now exists. At present in most schools the clinical teacher is a teacher mainly because he is fortunate enough to control a hospital service, and for this reason has been appointed on the university staff. In his appointment the school has no choice, for it must have for its students the advantages of the clinical material which he controls. Whether he be good, bad or indifferent, as physician, teacher or investigator, he must be retained as long as he holds his hospital position. He, on the other hand, is handicapped by the regulations and restrictions of a not always sympathetic lay board of hospital management and, more important still, by the absence of proper laboratory facilities and the aid of his own colleagues in the departments of bacteriology, immunology, pathology and pathological chemistry. These departments are coming more and more into active participa-

¹⁷ Bevan, *loc. cit.*

tion in hospital work, in diagnosis, prognosis and treatment, and should be as closely affiliated with the hospital as are the clinical chairs. Those of you who have read "The Corner of Harley Street,"¹⁸ a most delightful series of letters by an English consultant, may remember the words quoted by the author from a lecture of a brother consultant to postgraduates. Said the lecturer:

Gentlemen, I should like the day to dawn when I could be met at the door of my hospital by a trained chemist, a trained bacteriologist, a trained pathologist, so that when I come to some complicated case I could say, "Chemist, a part of this problem is yours, take it and work it out. Bacteriologist, perform your share in elucidating this difficulty. Pathologist, advance, and do likewise."

These are not idle words. Since Ziemssen in the middle eighties established in Munich the principle of a clinical laboratory in the hospital, the idea has spread rapidly, until now every hospital worthy of the name has its clinical laboratory for the routine procedures of diagnosis. But this is not sufficient. The clinical chief must have the close cooperation of his colleagues in the departments of pathology, bacteriology, physiology and chemistry, and the student likewise must have the outfits of these departments at hand to aid him in his clinical studies. It is no longer enough to depend on the simpler procedures for the examination of urine, sputum, blood and other body secretions and fluids. The transportation across the city of tissues or fluids for examination in the laboratories of the school can no longer be countenanced. The progress of modern medicine, especially in pathological chemistry and immunology, demands for the benefit of the patient as well as for the proper instruction of the student, detailed and

oftentimes prolonged examinations under the hospital roof or at least within the boundaries of the hospital yard, and under the control not of assistants or internes, or dependent on occasional visits of a professor of pathology, bacteriology or chemistry, but under the constant supervision of such experts who do their teaching and research in the hospital and contribute their share to the diagnosis, care and treatment of the ills of the patients. This is the ideal of social service in medicine, the goal of all effort in medical education and research; and it is not Utopian. Already the University of Toronto has transferred its departments of pathology, bacteriology and pathological chemistry to the grounds of the hospital which furnishes its clinical instruction. Here not only the elementary instruction is given, largely aided by an abundance of fresh material from the hospital, but each advanced student serving as clinical clerk in the wards has always his desk, well-equipped locker and special outfit for the detailed investigation of his clinical material by laboratory methods, and moreover, has always at hand his teachers in the laboratory branches to aid him in his clinical investigations. It was my good fortune recently to go over these departments with Professors Leathes and MacKenzie, who explained their workings to me. When I expressed my satisfaction at the ideal union of clinical and laboratory methods Professor Leathes said quietly, and as if there could be no other point of view, "Yes, we expect a student working in the wards to use in diagnosis the methods of pathological chemistry as he does his stethoscope." Do you know what this means? It means that the amphitheater clinic and the didactic lecture are to follow the two-year and three-year course and that the methods and instruction of the

¹⁸ "The Corner of Harley Street, being some Familiar Correspondence of Peter Harding, M.D.," Houghton Mifflin Co., 1911.

laboratory years are no longer to be divorced from the clinical teaching of the later years of the curriculum. It means that men are to be trained by the "do it yourself" method to become practitioners with power of accurate diagnosis and the "mind which is prepared" to take advantage of every "chance" observation and opportunity. It means that the newer methods of biological, physical and chemical diagnosis, evolved through laboratory effort, are to work a transformation in medical teaching and medical practise analogous to that which came in the middle of the past century through the introduction of exact methods of physical examination. As physical diagnosis raised medicine above the plane of objective diagnosis and revealed the morphological changes in diseased organs of the interior of the body, so now the methods of physiological chemistry and immunology are destined to reveal the changes in the cells and fluids of the body which are dependent on intoxication, infection and altered metabolism and thus bring about an advance in methods of diagnosis, the fruits of which are almost beyond our powers of imagination.

Herein lies the most potent argument for close affiliation of school and hospital. The task, both from the teaching side and from the research side, demands united effort, common use of material and common financial responsibility. While any contract between university and hospital must leave the general support of the hospital in the hands of the hospital management, the school must be prepared to pay the salaries of attending staff, the cost of equipment and the expenses necessary for teaching and research and to assume the responsibility for the medical and surgical care of the patients and the general conduct of the scientific work. On the other hand, the

hospital should leave the matter of appointments, subject to its nominal approval, entirely in the hands of the school, with the understanding that withdrawal or resignation from the school automatically would sever connection with the hospital, and *vice versa*. Such an arrangement settles most of the problems of medical education. Continuous service and freedom in the appointment of clinical teachers come as a matter of course. Teaching and investigation can be carried on without interruption. The student becomes a part of the hospital routine and is not an onlooker with limited privileges. The laboratory departments of the first and second years unite to aid the work of the clinicians in the hospital. Clinical teachers may be promoted, if deserving, or may be called from any part of the country, or from abroad; the choice no longer depends on local hospital appointments or on the selfish interests and friendships of local consultants, but on fitness, eminence and skill.

Teachers may be appointed on a university basis, devoting all or most of their time to the care of the patients, to teaching and to investigation. The heads of the departments of internal medicine and surgery certainly should be so appointed. Under such circumstances these men with their staffs could control a large body of students working relatively independently among the patients in the wards and in the special laboratories in or near the wards. In these clinical laboratories every student should have his own desk and outfit for microscopic, chemical and other methods of examination. Not merely apparatus for the simpler tests should be supplied, but as well every facility for prolonged bacteriologic examination, animal inoculation and detailed chemical and physiologic study.

Such a plan insures diagnostic ability and therapeutic skill by training the powers of direct observation as well as by instruction in the methods of indirect observation through the use of instruments of precision and the procedures of the chemical and biologic laboratories. The experimental method emphasized in the laboratory years is thus continued through the clinical years. Laboratory procedures naturally fall into their proper place in relation to the methods of direct observation, and as the student approaches each new disease in the spirit of the investigator and not as an onlooker he gains a point of view which can not fail to have an important bearing on his work as a practising physician.

The Hospital Year.—So much for the preparation which the training, facilities and opportunities of the modern medical school should offer as leading to the degree of doctor of medicine. Should the state and the public demand more? Yes, the state, through its machinery for the protection of the individual, should demand a fifth year of hospital work, and this the public would force the state to demand if the easy-going public was thoroughly familiar with the insufficient requirements of many of our state licensing boards. Indeed, some states are already drafting laws to protect their citizens from the products of the poor medical schools of a neighboring state—

For example, the state of Minnesota has enacted a law enforcing an educational qualification as to the training of physicians who are allowed to practise in that state. The law was adopted in order to protect citizens of Minnesota against the graduate of commercial medical schools in neighboring states, and particularly of Chicago. In the present state of medical education such a measure is entirely justifiable.*

*Pritchett, H. S., "Education and the Nation," *The Atlantic Monthly*, April, 1912.

Such a law not only protects the community against the improperly prepared graduates of the poor school, but it encourages the good medical school to increased efforts.

The hospital year as a prerequisite to licensure is to-day a live topic of discussion; to-morrow it may be in this and in other states a requirement legally stated.²⁰ Indeed it is difficult to see how the progressive state of New York, the educational system of which is so wisely controlled by a special board of regents, can much longer delay in establishing such a requirement. But why wait for the regents to force this upon the schools? Already 80 to 90 per cent. of the men in the better schools secure hospital appointments. Why should not the schools compel the small minority of those who do not secure a hospital to take a fifth year in clinical instruction in the hospital which it controls and thus be prepared for the requirement which must inevitably come in this and other states. I realize fully that the deans of our various schools are divided on this question. Some take the position that although the hospital year is an excellent requirement, the burden of finding the hospital instruction for all its graduates should not be placed on the school; that the duty of the university is ended when it has given four years of instruction and that the fulfillment of the added requirement is an affair of the individual. What does this mean in the last

* There is only one school at present which requires the fifth hospital year, and that is the University of Minnesota. No state boards at present require the hospital interne year. Those which to a certain extent have initiated practical tests at their examinations are Massachusetts, Minnesota, Ohio and North Dakota, and to a lesser extent practical tests are being used in Colorado and Michigan. (Personal communication from N. P. Colwell, secretary, Council on Medical Education of the American Medical Association.)

analysis? Simply this, that a school holding this point of view is either lax in its entrance requirements or at fault in its methods of instruction; otherwise it would not fear the failure of its graduates to secure internships. If this is true it has under the circumstances but one duty: as an educational institution, it must itself provide the fifth year of hospital work for its lame students. This is the point of view which is gradually forcing itself upon the school of the better grade, which, now that the pioneer stage of medical education is past, desires to itself complete the student's preparation, instead of turning him "over to others during this most valuable and important part of his preparatory work."²¹ The proposition of Professor Peterson, of Michigan, that the council on medical education of the American Medical Association should conduct an inspection and classification of hospitals on the same basis as the inspection of medical schools is most timely. The data thus obtained would do much to clarify the situation, and, doubtless, mutual agreements between certain schools and certain hospitals of the same class could be reached as to the distribution of graduates for interne service. Such a systematization would allow school and hospital alike to see their defects and to so rearrange their work as properly to care for the greatest number of properly prepared men. Only through the hospital year can we give the best type of practitioners to a most deserving but too confiding public; but to bring about the consummation of this ideal every university school and every community possessing a modern hospital must do its share.

These general remarks cover, in my opinion, the cardinal principles which

²¹ See Peterson, R., "The Relation of the Medical School to the Interne or Hospital Year," *Jour. Am. Med. Asso.*, LVIII., p. 723, 1912.

should guide the modern medical school. They can not, perhaps, in every community be enforced at once in their entirety, and doubtless now and then their adoption may be followed by backsliding, but no one who has given the subject serious thought can doubt that the future of medical education in this country depends on (1) the university school with a high entrance requirement, (2) instruction, in both laboratory and clinical branches, based on the method of observation and experiment, (3) clinical instruction in a hospital which the university owns or controls, (4) the principle of a fifth year of hospital instruction and (5) the fostering of the spirit of research.

And now finally let me congratulate Syracuse University on the high ideals it has set for itself in the conduct of its medical school. Your course has been watched by all who are interested in medical education. Your responsibility is greater than perhaps you realize; there are those praying for you to continue your present progressive system, others hoping you may fail. Each group desires to point to you as an object lesson. I have full confidence, however, that the wise trustees of your university, supported and encouraged by your alumni and the physicians of Syracuse and its surrounding territory, will not only maintain the present high standards, but will inaugurate still greater advances and thus ensure for the practitioner of medicine in this community the "prepared mind" of Pasteur's adage.

R. M. PEARCE

THE WORK OF COLONEL GORGAS

THE degree of doctor of laws was conferred on Colonel W. A. Gorgas by the Johns Hopkins University on June 11. In presenting him for the degree Dr. William H. Welch said:

Mr. President: In behalf of the academic council I have the honor to present for the honorary degree of Doctor of Laws Dr. William Crawford Gorgas, colonel in the Medical Corps of the United States Army, member of the Isthmian Canal Commission and chief sanitary officer of the Isthmian Canal Zone, formerly president of the American Medical Association, physician and sanitarian of the highest eminence, who by his conquests over pestilential diseases has rendered signal service to his profession, to his country and to the world.

With high administrative capacity and with full command of the resources of sanitary science Colonel Gorgas has given to the world the most complete and impressive demonstration in medical history of the accuracy and the life-saving power of our knowledge concerning the causation and mode of spread of certain dreaded epidemic and endemic diseases. He it was who, by application of the discoveries of Major Reed and his colleagues of the Army Yellow Fever Commission, was mainly instrumental in freeing Cuba of yellow fever, and he it is who, in spite of obstacles and embarrassments, has made the construction of the Isthmian Canal possible without serious loss of life or incapacity from disease—a triumph of preventive medicine not surpassed in importance and significance by the achievements of the engineer.

In the conquests of science over disease, in the saving of untold thousands of human lives and human treasure, in the protection of our shores from the once ever-threatening scourge of yellow fever, in the reclamation to civilization of tropical lands—in results such as these are to be found the monuments of our laureate, his victories of peace, to which this university now pays tribute by such honor as it can bestow.

SCIENTIFIC NOTES AND NEWS

THE honorary degree of doctor of laws has been conferred by the University of Illinois on Vice-president Thomas J. Burrill and Comptroller Samuel W. Shattuck, both of whom retire at the end of the academic year after an active service of over forty years.

OXFORD UNIVERSITY has conferred its doctorate of science on Mr. A. P. Maudslay, president of the Royal Anthropological Institute of Great Britain and Ireland.

DR. E. RUTHERFORD, F.R.S., Langworthy professor of physics at Manchester, has been

elected a corresponding member of the Imperial Academy of Sciences, Vienna.

DR. L. A. BAUER has been invited to deliver the Halley lecture on "Terrestrial Magnetism" at the University of Oxford, England, in May, 1913. He was elected a fellow of the American Academy of Arts and Sciences at the annual meeting in May.

AT the sixth annual meeting of the British Science Guild, held on May 17, a silver plate was presented to Sir Norman Lockyer, inscribed as follows: "Presented to Sir Norman Lockyer, K.C.B., LL.D., D.Sc., F.R.S., by members of the British Science Guild, on his seventy-sixth birthday, May 17, 1912, as a token of their esteem and as a recognition of his patriotic labors to promote the application of scientific principles to industrial and general purposes." Sir Norman was unfortunately prevented by ill-health from being present.

WE learn from *Nature* that Dr. D. H. Scott, F.R.S., president of the Linnean Society, has been elected a foreign member of the Royal Danish Academy of Sciences and Letters, and of the Royal Society of Sciences, Upsala.

It is reported that Professor Lanfranchi, of the University of Parma, who has been engaged for several years in the study of sleeping sickness, has been infected by the disease in a severe form, and has been taken to the Pasteur Institute in Paris for treatment.

PROFESSOR MAYVILLE W. TWITCHELL, head of the department of geology in the University of South Carolina, has resigned to accept the position of assistant state geologist of New Jersey. He will reside in Trenton where he will take up his new duties early in July.

AT the meeting of the New York Section of the American Chemical Society, held on June 7, Professor Herbert R. Moody, of the College of the City of New York, was elected chairman of the section for the coming session to take the place of chairman-elect A. B. Lamb, who is going to Cambridge. The New York Section increased its membership over

a hundred during the past year, giving it a total of nearly a thousand members (962).

EDWIN B. FROST, director of the Yerkes Observatory, has sailed for England and will probably remain in Europe until next spring. In his absence, correspondence for the Yerkes Observatory should be addressed to Mr. S. B. Barrett, *secretary*. The duties of managing editor of *The Astrophysical Journal* have been assumed by Professor Henry G. Gale, of the department of physics, University of Chicago.

PROFESSOR F. R. MOULTON, of the University of Chicago, is sailing for Europe, where he will attend the International Congress of Mathematicians at Cambridge, England.

PROFESSORS R. BURTON-OPITZ and Frank H. Pike, of the department of physiology of Columbia University, have sailed for Europe. The former has a leave of absence until February, while Professor Pike will spend the summer abroad. Mr. Ernest L. Scott, of the University of Kansas, goes to Columbia as instructor in physiology.

PROFESSOR FRANCIS H. HERRICK, of Western Reserve University, will be absent on leave during the coming year in Europe.

DR. ALEŠ HRDLÍČKA, curator of the division of physical anthropology, U. S. National Museum, has gone to the Upper Yenisei region of Siberia, to carry on studies and collections for the museum and the California Exposition. From Upper Yenisei he will go to Irkutsk, and such other parts of Mongolia and Turkestan as he may have time to visit. After leaving Siberia he will visit Kiachтата in Chinese Turkestan, Mongolia, and then follow the road to Urga, whence he will proceed along the old caravan route to China proper.

DR. RILEY D. MOORE, aid division of physical anthropology, U. S. National Museum, and Mr. John B. Harrington, ethnologist, of the School of American archeology, Santa Fé, New Mexico, will make a trip to St. Lawrence Island, Alaska, to make observations on the tribe of Eskimo which occupies that island. The data and material gathered are to

be incorporated in the exhibits of the U. S. National Museum at the California Exposition in 1915.

DR. D. B. MACMILLAN, of the Crocker Land Expedition, and Mr. A. C. Bent, of the Smithsonian Institution, have left in the power boat *George Borup* for the coast of Labrador on an ornithological and ethnological expedition. It has been erroneously announced in the newspapers that Mr. MacMillan has sailed for Crocker Land, the expedition to which will be undertaken next year.

THE University of Illinois has celebrated the fiftieth anniversary of the passing of the Land Grant Act by unveiling the portrait of Jonathan B. Turner in the Illinois Farmers' Hall of Fame. President James in his commencement address on the Life and Labors of Professor Turner said: "All honor to Justin S. Morrill! But great as is the honor due to Mr. Morrill, the real credit for originating the plan incorporated in the Land Grant Act belongs to an Illinois farmer and professor, Jonathan B. Turner." The portrait of Professor Turner was presented by his daughter, Mary Turner Carriel, who was present as the guest of the university.

MAJOR GENERAL E. R. FESTING, F.R.S., known for his researches in physics and at one time director of the Science Museum, London, died on May 16, aged seventy-three years.

MR. B. J. AUSTIN, lecturer in physiology and hygiene at University College, Reading, and latterly emeritus professor of botany, died on June 2, aged eighty-three years.

THE U. S. Civil Service Commission announces an examination on June 5, 1912, to fill a vacancy in the position of agricultural propagator in the Philippine Service, at a salary of \$1,600 per annum, and of xylotomist, at \$1,000 per annum, in the Forest Service, at Madison, Wis.

THE annual meeting of the Swiss Association of the Natural Sciences will be held at Altdorf on September 9 and 10. A cordial

invitation is extended to American men of science to be present.

THE first International Congress of Comparative Pathology will be held in Paris, from October 17 to 22, under the presidency of Professor Roger.

THE proceedings of the International Radiotelegraphic Convention, at which thirty-five states are represented, were opened on June 4 at the Institution of Electrical Engineers, London.

INFORMATION has been transmitted to this government through the customary diplomatic channels, that the International Congress of Hydrology, Climatology and Geology, originally appointed to be held at Madrid from October 15 to 27 of the present year, has been postponed to the same dates (October 15 to 27), 1913. The participation of American scientists, scientific associations and higher institutions, is earnestly solicited by the Organizing Committee.

THE secretary of state for India has appointed a committee to inquire and report as to the facilities available for Indian students for industrial and technological training in Great Britain, with special reference to the system of state technical scholarships established by the government of India in 1904. The committee is constituted as follows: Sir Theodore Morison, K.C.I.E. (chairman), and Sir Krishna Gupta, K.C.S.I., members of the Council of India; Mr. J. H. Reynolds, M.Sc., lately principal of the Municipal School of Technology at Manchester, and Professor W. E. Dalby, M.A., professor of civil and mechanical engineering at the Imperial College of Science and Technology at South Kensington. The secretary of the committee is Mr. P. H. Dumbell, of the India Office.

THAT the forest cover of the White Mountains has a distinct and measurable effect upon the navigable streams which head in that region is the statement of the United States Geological Survey. The director of the survey has filed his preliminary report on the White Mountains with the National Forest Reservation Commission, and, as earlier

announced, the findings are favorable to the purchase of lands under the Weeks law. The report is based on the results of investigations and specific field tests which have been carried on during the last year. While the survey has been subjected to criticism owing to its refusal to submit a perfunctory report assuming that a known and definite relation exists between forests and stream flow in the White Mountain region, the outcome of its investigations precludes the possibility of criticism by those who have opposed the acquisition by the government of any forest lands, on the theory that forest preservation does not affect stream flow. The hydrometric showing presented in the preliminary report covers results on two small, almost exactly similar drainage basins of about 5 square miles each, on the east branch of Pemigewasset River, one largely clothed with virgin timber and the other deforested and burned. Measurements of precipitation over the areas and of the run-off of the respective streams show that not only was the snow held better in the forested area, but that during a period of 17 days in April, including three extended storms, the run-off of the stream in the deforested area was a comparative flood—practically double that of the stream flowing through the forested area.

THE newspapers some weeks since contained the announcement of the discovery of a billion tons of iron ore in Fulton County, Pennsylvania, specifying red, brown and carbonate ores, ranging from 57 to 63 per cent. of iron, and found in Dickey's Mountain, Lowrie's Knob and the Meadow Ground. The geology of Fulton County is well known from the reports of the State Geological Surveys, and the impossibility of the case is apparent to any one who will read these reports and study the maps for a moment. A billion tons of iron would occupy a volume nearly equal to the mass of the three "mountains" named, and carbonate of iron when chemically pure contains only 48 per cent. of iron, and brown ore less than 60 per cent. Nevertheless, to ascertain what might have given rise to the reports, Director Smith, of the United States

Geological Survey, sent Geologist George H. Ashley into Fulton County to make an investigation. He reports that undoubtedly these hills contain several million tons of low-grade red iron ore and may contain a small amount of high-grade brown ore and more low-grade brown ore. Mr. Ashley found that three drill holes have been sunk into a shallow, canoe-shaped basin of red shale forming the "Meadow Ground." The basin is readily measured in length, breadth and depth. If all ore, it would hardly contain 30 million tons. The rocks are well exposed and show practically no iron except the iron coloring the rocks. Lowrie's Knob, if a solid hill of ore, would contain only about 100 million tons. The rocks here are likewise well exposed. A pocket of brown ore has been worked out on the east side by the old Hanover furnace, yielding about 75,000 tons of ore (46 per cent. iron). The "cove" fault runs through Lowrie's Knob and Dickey's Mountain, so that the rocks forming them stand on edge and locally are crumpled. Dickey's Mountain contains some low-grade sandy iron ore on the west side, possibly five million tons, as the bed cuts off against the fault. A little brown ore, 14 inches by 2 feet thick (38 per cent. iron), was dug for the Hanover furnace, but abandoned as impossible. The black shales of the Devonian are present in the region, but no suggestion of carbonate ore was seen.

A U. S. WEATHER BUREAU station has been installed at the University of Notre Dame, Notre Dame, Ind., by Mr. J. H. Armington, of the Chicago Station. Among the instruments located in the Science Hall, there is a triple register for wind velocity, wind direction, rainfall or sunshine as received on the roof by the anemometer, wind vane, tipping bucket rain gauge or sunshine recorder respectively. There are also two mercurial barometers and their barograph as well as complete equipment in the way of tables, record-books, report-books, etc., a few duplicate instruments and a snow gauge. There are on the roof, in a sheltered tower, wet and dry bulb, and maximum and minimum tem-

perature thermometers with their thermograph. Professor Thomas A. Irvin, Ph.D., of the department of physics, has charge of this station which, in conjunction with the university observatory, posts on the Science Hall Bulletin complete daily reports of meteorological and astronomical observations.

SIR WILLIAM HARTLEY has presented to the University of Liverpool a wireless installation designed mainly with a view to experimental and research work of an advanced nature. For transmitting purposes a short aerial about 100 feet above ground has been erected on the roof of the electrical laboratory, and in connection with this a standard Marconi receiver has been arranged such as is used on board ship, and this combination forms a small standard power station. This has been licensed by the post office, and time and meteorological messages are received twice daily from the Eiffel Tower in Paris. The transmission range is only about 40 or 50 miles, save under very favorable conditions, as the post office regulations limit the amount of power that can be sent out of a station to one third horse-power. Professor Marchant, of the electrical engineering laboratories, is at present engaged in testing detectors, but later in the year he proposes to hold wireless classes for ships' captains and others interested.

UNIVERSITY AND EDUCATIONAL NEWS

MR. WALTER MORRISON, of Baliol College, has given \$10,000 to Oxford University as the nucleus of a pension fund for professors.

J. CARLETON BELL, Ph.D. (Harvard), managing editor of the *Journal of Educational Psychology*, and director of the psychological laboratory in the Brooklyn Training School for Teachers, has been appointed professor of the art of teaching in the University of Texas. Dr. Bell will devote his attention chiefly to the experimental investigation of problems of teaching.

IN the College of Medicine of the University of Virginia, as we learn from the *Journal* of the American Medical Association, Dr. Jacob Michaux, one of the original members

of the faculty, resigned the chair of obstetrics and was made professor emeritus of obstetrics. Dr. Paulus A. Irving, who has moved to Farmville, Va., was made emeritus professor of pediatrics. Dr. John F. Winn, formerly professor of clinical obstetrics, was elected professor of obstetrics, and Dr. Virginius Harrison associate professor of the same branch. Dr. Francis W. Upshur was chosen professor of materia medica and therapeutics, and Dr. C. Howard Lewis was made professor of pharmacology and also associate professor of physiology, these two physicians dividing the chair which was formerly held by Dr. Virginius Harrison. Dr. E. C. L. Miller was elected professor of bacteriology and physiologic chemistry.

MR. HARRY N. EATON, A.M. (Harvard, '06), instructor in geology in the University of Pittsburgh, has been appointed assistant professor of geology in the Pennsylvania State College.

AT a recent meeting of the Yale Corporation, Jacob Parsons Schaeffer, M.D., Ph.D., was promoted from assistant professor to be professor of anatomy in the Yale Medical School.

NATHANIEL CORTLANDT CURTIS, professor of architecture in the Alabama Polytechnic Institute, has recently been elected to the chair of architecture in Tulane University of Louisiana.

E. S. McCANDLISS, a graduate of Purdue University of the class of 1908, has been appointed instructor in civil engineering in the Missouri School of Mines.

PROFESSOR B. H. HIBBARD, of the Iowa State College, has been appointed associate professor of agricultural economics in the College of Agriculture of the University of Wisconsin.

FRANCIS E. LLOYD, for four years professor of botany in the Alabama Polytechnic Institute, and plant physiologist to the Alabama Experiment Station, has been appointed MacDonald professor of botany in McGill University. Professor Lloyd's address will remain unchanged till September 10 next.

DISCUSSION AND CORRESPONDENCE

THE DOME THEORY OF THE COASTAL PLAIN

TO THE EDITOR OF SCIENCE: Recently the writer's attention has been called to an article published in SCIENCE of April 5 by Mr. G. D. Harris in which he claims the entire credit for the discovery and promulgation of the "dome theory" of the accumulation of oil in the Gulf coastal plain. The statements in this paper are so misleading to those unfamiliar with the history of the development of this region, that the writer feels it necessary to state briefly some of the facts and to quote some of the geologists who were familiar with the early work.

The article in question is as follows:

OIL CONCENTRATION ABOUT SALT DOMES

In several national, state and private publications the writer has called attention to the remarkable concretionary growth and bodily movement upwards of huge masses of rock salt in Cenozoic deposits along the Gulf border. The bearing of the structures produced in the neighboring beds by such growths and movements on oil concentration was duly set forth in Bulletin 429 of the U. S. Geological Survey. Recently he has had the opportunity of testing the value of his "dome theory" for locating oil "pools" in a region far away from any known oil occurrences. Reference is here made to Pine Prairie, south central Louisiana, where the Myles Mineral Company has had the courage to try out the theory and has discovered by the means a new oil field. The director writes: "I consider this a most remarkable vindication of a theory originated by you, and we attribute a large measure of our success thus far to your advice."

Space should not be taken here to discuss the probable exact location of oil in connection with these domes; that is a matter depending largely on the approach of the salt domes to the surface, size, location, etc. These matters have been outlined at least in the U. S. Geological Bulletin already referred to. But the location of oil by means of a theory unheard of ten years ago does seem worthy of record at this time. Another fact that should be impressed upon the mind of the public now is the absolute worthlessness of stocks in companies putting down wells "near" the dis-

covery well. This matter has, however, been discussed in Bulletin 429.

G. D. HARRIS

CORNELL UNIVERSITY

At the risk of presenting a rather personal matter, the writer will briefly outline the history and cause of his investigations of the coastal plain region during the past eighteen years in search of deposits of mineral value. As early as 1894 he bored with diamond drills on Jefferson Island, Belle Isle, Weeks Island and Anse La Butte, La., discovering in each place a huge mass of rock salt of limited area but of great depth. At Jefferson Island pure rock salt was penetrated to a depth of twenty-one hundred (2,100) feet without finding bottom, and at Belle Isle rock salt, having a depth of twenty-seven hundred and forty (2,740) feet (pierced in 1907), was discovered with paraffine oil and large lenses of pure sulphur.¹

The successful results attained by his explorations in Louisiana led the writer to extend the study of a nascent "dome theory" into Texas and to apply it to the various phenomena occurring on Spindle Top; a low elevation of only ten to twelve feet above the surrounding prairie, and to drill finally on this dome against the advice of his friends, with the well-known result that the largest well ever discovered in the United States and variously estimated at from 75,000 to 100,000 barrels per day had its birth on the tenth day of January, 1901.

The success of this well demonstrated the possibility of attaining economic results by drilling for oil, gas and sulphur on the domes of the coastal plain. This theory held good throughout the hundreds of wells drilled around Spindle Top in the effort to extend the area laterally without results, however, for it was subsequently proved that if the original well had been located only sixty-five feet further to the northwest there would not have been a discovery well.

¹ See "Rock Salt in Louisiana," by A. F. Lucas, in *Trans. Am. Inst. Min. Eng.*, 1899, also *Jour. Ind. and Eng. Chemistry*, Vol. 4, No. 2, February, 1912.

It must be noted that this well was not located on the axis of "the central dome," hence the great risk incurred in its drilling, and whoever may claim that this dome theory does not apply, and "fools" around the rim of the dome, stands a good chance to lose himself in the quagmires of gumbos and the unconsolidated sands with which the domes are surrounded. This was proved by hundreds of wells drilled around the Spindle Top dome, not in an effort to prove a theory, but rather in the strenuous effort to extend laterally the area of the productive territory. The dome theory as advanced by the writer in the early days of the Spindle Top field to Dr. C. Willard Hayes and Professor R. T. Hill, of the U. S. Geol. Survey, to Mr. Lee Hager, consulting geologist, Houston, Texas, Dr. Wm. B. Phillips, now director of the Mineral Survey, Austin, Texas, and to Mr. Eugene Coste, of the Canadian Mining Institute, has been generally accepted.

Mr. Hager, in a letter to the writer, dated May 27, 1912, from Houston, Texas, writes as follows:

All of us down here, at least those who know the facts, are fully aware that the credit of first bringing the significance of these coastal domes to the attention of the world belongs solely to you, and I can not see that there has been any advance made upon your ideas even to this day.

Professor R. T. Hill, in the *Jour. of the Franklin Inst.*, Aug. and Oct., 1902, and in *Trans. Am. Inst. Min. Eng.*, Vol. 33, states:

Before the discovery of Spindle Top there was only one man whose ideas—although not yet coordinated into a theory—approximately fitted the observed conditions. Of course I refer to Captain Lucas, who, in his explorations of the Coastal Plain, seeking successively salt, sulphur and oil, had observed the associations of oil, sulphur, sulphuretted hydrogen, gas, gypsum, dolomite and salt, constituting collectively what might be termed the oil-phenomena representing a group of secondary products as distinguished from the mother-strata or sediments out of which they have been produced. Moreover, so far as I am aware, he first pointed out the existence of anticlinal hills in the Coast Prairie and their connection with the oil-phenomena. . . . Captain Lucas early noted that

sulphuretted hydrogen escaping from the earth under certain conditions deposited sulphur in crevices near the surface. Such phenomena he observed at Spindle Top before commencing his well. At High Island, Galveston County, Texas, work was temporarily suspended on a well hole and the orifice stopped with hay in order to prevent obstructions from débris. Afterwards when the plug was withdrawn the hay was found to be imbedded in a matrix of sulphur, undoubtedly deposited by the escaping gas. . . . No topographic surveys have ever been made of any portion of the Coastal Prairie, and hence the slight irregularities of its contour are discernible only with difficulty. Until Captain Lucas's investigations, certain low elevations which have since become the most important features of the landscape were hardly noticed. I allude to low swells or hills, such as Spindle Top, which occur here and there and now attract attention from their supposed relation to the occurrence of oil beneath them. . . . In the generally monotonous monoclinical structure there are a few wrinkles or small swells likely to escape the eye of even the trained observer, and yet of a character which may have an important bearing on the oil problem. These are the circular or oval mounds already described which were first recognized by Captain Lucas. When he pointed out Spindle Top hill to me, my eye could hardly detect it, for it rises by gradual slope only ten feet above the surrounding prairie plains. I was still more incredulous when he insisted that this mound, only 200 acres in extent, was an uplifted dome. But Captain Lucas said that I would be convinced of the uplift if I could see Damon's mound in Brazoria County. In August, 1901, I visited that place and then returned for a second look at Spindle Top and was convinced that if these hills are not recent quaquaversal uplifts no other known hypothesis will explain them.

Mr. Marius R. Campbell, a later but impartial judge, in summing up the progress that had been made,³ states:

In the general wave of oil explorations and development that swept over the country from the Appalachian region, when that was at the height of its production, oil was found at Corsicana, Tex., in flat-lying rocks that were similar in geologic structure to the rocks of the mid-continent field

of Kansas, and it seems to have been generally assumed that there were no new problems in the oil fields of the Gulf coast. Captain A. F. Lucas, however, was not of this opinion. For years he had been exploring the salt beds of Louisiana, and he appears to have been the first to fully appreciate the dome structure of such deposits, and to have been imbued with the idea that they contained not only salt and sulphur but also petroleum. His famous gusher on Spindle Top near Beaumont, Texas, struck oil January 10, 1901, and fully demonstrated the correctness of his theory, although this was not generally accepted by the geologists best acquainted with the field. Some endeavored to convince the public that the conditions at Spindle Top were similar to those at Corsicana, and that the pool would be found to have considerable lateral extent, but the oil drillers soon disproved this idea, and showed that oil was practically limited to the dome and small mound which constituted its topographical expression.

There are scattered throughout the Texas Coastal Plain many well-known domes which have been prospected directly or indirectly by the writer, the most important of which are known as Saratoga, Sour Lake, Big Hill, High Island, Damon Mound, Keiser Mound, Barber Hill, Hoskins Mound, and Bryan Height. In the last-named mound the writer found in 1901 hydrogen sulphide under heavy pressure and also native sulphur which is now being heavily exploited by a New York syndicate, which hopes to make this equal to the sulphur mines of Louisiana. Whether or not this mound is also a salt dome remains to be proved by deeper drilling.

In conclusion it appears that the claim made by Mr. Harris in locating wells at Pine Prairie, as noted in his article in *SCIENCE*, quoted above, was quite premature, as *The Oil and Gas Journal*, of May 23, states:

Pine Prairie, that had promise of developing another Gulf coast field, has so far failed to produce other than disappointments. Of the five tests now drilling three are at depths considerably past that at which the Myles Mineral Company found pay in its No. 8, the discovery well, and have failed to drill into anything encouraging to test. The Producers Oil Company set screens in No. 1 Le Danois-Hudspeth at about 2,000 feet and made a try for a well, but the effort failed to be pro-

³ *Economic Geology*, Vol. VI., No. 4, June, 1911.

ductive, and as a result the pipe has been pulled out, broken down and the hole abandoned.

A. F. LUCAS

WASHINGTON, D. C.,

UNIVERSITY CONTROL

LETTERS FROM YALE UNIVERSITY

It is quite unnecessary for me to speculate regarding what such a system as you propose would be. Exactly this system is in effect in New Haven. In fact Yale University consists of a collection of separate schools. Each has its own funds and almost complete autonomy. These funds are indeed held by the corporation and president, but in the main each department spends its income as its own judgment dictates with little interference from the university authorities. Each faculty nominates to the corporation its own new members, and as the corporation nearly always confirms nominations this amounts to election by the faculty. Each faculty elects its own dean who presides over its meetings. Its committees are either appointed by the dean (never by the president) or elected by the faculty itself. Such conditions fulfill almost exactly the suggestions of your pamphlet. The question is then: Does this system of university government attain the objects to which you look? I gather from your pamphlet and from previous articles of yours that the happiness of the professor is the principal object toward which you are striving. This is certainly achieved at Yale to a degree equalled, perhaps, nowhere else in America. Of course, satisfaction with one's position makes for loyalty and other incidental advantages; but is the happiness of the members of the faculty the principal object for which a university exists? Is not that form of university government best which provides the most ready adaptation of the university to the community which it serves? Ought not any form of university government to be judged by the degree of progressiveness of the institution having this government? I am inclined to believe from personal observation that in spite of all the advantages of democratic government which Yale enjoys—and which any university planned as you sug-

gest would doubtless have—a more centralized control would make for great interdepartmental cooperation and a more ready adoption of new measures than is afforded by such democratic government. After all every institution inevitably adapts itself to the views of the masters whom it serves, that is, to those from whom it obtains funds. The state universities depend upon the people of the state, the endowed universities upon their alumni. It is an article of faith with every loyal alumnus that his alma mater is perfection. With a body of "loyal" alumni viewing every change with suspicion and with a faculty thoroughly satisfied with things as they are, there would not be under the system of government which you propose any sufficient machinery for the initiation of change. There are few—if any—of the endowed universities at least which would not in my opinion benefit enormously from having a Woodrow Wilson in the presidential chair. Certainly the one institution that has enjoyed this advantage failed to reap the full benefits therefrom, because the presidency carried with it too little power and the other elements in the university too much.

There are many things in the statement which are in harmony with my own views. I have always been, and still am, a strong believer in the desirability of autonomy for the individual schools or departments of a university. To-day our universities are so large and so complex in character that it is impossible to have adequate control over all the varied interests of the university in the hands of a central body. I believe in the desirability of a corporation, or board of trustees, in whom rests final authority for all matters pertaining to the university; but I think that the initiative, the control and the general management of a department or school of the university should rest in a governing board or subcommittee, whatever you choose to call it—with a chairman or dean or director, who is given, subject to said board, a large measure of authority. The corporation of the university should be representative of all the interests of the university, so far as possible. Here at

Yale, where alumni representation is perhaps as strong as in any university, we have been reaching out of late years further and further, so that to-day we have on our corporation various men elected from the alumni; but in addition we have what is called an alumni advisory board, a body composed of representative alumni from all over the country; but while having no real authority, they are able after discussion among themselves to present to the corporation suggestions and advice, sometimes of great value. This, no doubt, is a move in the right direction. I have advocated, however, what I see you advise here, the desirability of a movement in the other direction, namely, of closer relationship between the corporation and the professors or other officers of the university. At present, in most institutions, if not in all, the president is the sole person on the board of trustees or on the corporation who is supposed to be in touch with the activities of the faculty or faculties. At present, however, with the large size of the university, the president does not have, and can not necessarily have, an intimate knowledge of what is going on. I believe, therefore, very thoroughly in the idea of direct or indirect representation on the corporation of the university of the faculty in the persons of say three professors, who might sometimes be the deans of the individual departments. In your third paragraph regarding the unit of organization within the university, you have outlined exactly what we have in force here. Thus, in the Sheffield Scientific School, the scientific department of Yale, our governing board, composed of permanent professors, about twenty-four in number, is the deliberative and active body, subject of course to the corporation. The size of this group is such that it is thoroughly efficient. Your fourth paragraph is likewise in harmony with our customs and our beliefs in the Sheffield Scientific School. The director is elected every five years. He is given a large measure of authority, but all the same he is subject to the governing board of the school, and there is a very distinct autonomy. Professors and assistant professors, and indeed instructors, are

all selected by the governing board, or in practise by committees appointed by the governing board, subject to their approval. Nominations then go from the governing board to the corporation for confirmation. Regarding the salaries, personally I am a strong believer of having the salary the same for all officers of the same grade, subject possibly to advances on the basis of years of service.

(1) Approved, except that the treasurer should be responsible to the president, as otherwise he could hamper the actions of the president by lack of financial support. (2) The professors should elect the president to continue in office at the pleasure of the trustees and removable only by the trustees. I think his salary should be larger and his position more dignified. I do not believe in electing an executive officer and then not letting him execute. The present autocratic attitude of certain presidents would tend to be limited if they were elected by the professors and the professors were able to remonstrate to the trustees; but it is equally clear that the efficiency of the president should not be hampered by the necessity of keeping in favor with all the professors. (3) Approved. (4) There is danger of professors being required to waste too much time in executive work and keeping to themselves powers which should be delegated to executive officers. I think the president should assume the burden of finding candidates, weighing their qualifications, deciding what positions should be filled; but he should do this in consultation with committees of the professors and his action in regard to all appointments should be ratified by faculty vote. (5) The idea of general faculty meetings at occasional intervals is a good one, though as you state not much business can be transacted in such a large body. In conclusion, I would differ from the plan outlined in conferring more working power on the executive officers and leaving the professors free for teaching and research, but at the same time make the executive officers responsible to the faculty as well as to the trustees.

On the whole I think I approve of the policy you set forth. There are minor details I should wish to consider more. You know that to a very considerable degree what you advocate is the plan at Yale University. Our departments and notably this school are in great measure autonomous. It seems to work well here. It has long been a question in my own mind if a unit of 1,000 students with the necessary instructors, buildings and equipment was not as large a one as could be handled by one man as president, dean, director or what you will to obtain maximum efficiency. This in a way seems to be the army view of it, where the regiment of about this magnitude of unit has its colonel. The kind of management that a colonel must give is what I think one should expect (the difference between the two affairs being properly considered) from a dean or director. I mean that personal supervision of matters that comes of personal knowledge. And when the university is 5,000 in size the president would do well to become a general.

I think you are correct in believing that our universities need remodeling. We have a democracy here at Yale and yet the most effective administration is in the Sheffield Scientific School, where democracy and autocracy are combined. After all administrative heads must have power to act and a good administrator does not work well hedged in by all sorts of limitations. It takes the snap out of one to work under restrictions. The more I see of democracies, the more I come to believe in a limited monarchy.

The more I see of university management the more I feel in a cloud as to what is the best thing. At the present time I haven't any definite opinions on the subject. All I can say is that to me the question of the actual formulation of rules to govern a university is much less likely to have a real influence than the spirit and ideas of the people connected with the university. I can not help thinking that the latter will be the dominant factor, whatever organization may be laid down.

I thoroughly agree with the proposed plans (3), (4), (5), in their essential details. Your views on these points are, I believe, correct. With regard to (2) my reply would depend somewhat on the interpretation of your words. The expression "expert knowledge of education" is the point at issue. Our college and university presidents ought in many cases to talk less and become more familiar with the men, *i. e.*, teaching staff and their work. I am not at all certain that your further suggestions under (2) are expedient. Suggestion (1) does not appeal to me as presented. I do not believe in extreme democracy. However, I prefer to omit discussion of this point, as I have never given any serious thought to it.

I do not wish to be drawn into the discussion. I wish to tell you, however, that I heartily approve of the policy of SCIENCE to air the university situation. Its fearless attitude is very needful, in my humble opinion.

I am in accord with the general principles. At the present time the president of most American universities is "neither fish nor flesh nor good red herring." He is so overburdened with administrative duties that he is unable to inform himself as to the educational aspects of the different departments of the university. I speak feelingly on this point because I have been more or less intimately connected with several university medical departments, and it has been my experience that university presidents need about as much education on the subject of medical schools as ordinary intelligent laymen. I dare say the same is true of law and divinity schools, etc. I do not mean to deny that there are brilliant exceptions to this general statement. I am therefore very strongly in favor of the division of the work now accomplished by university presidents into an executive portion, to be taken care of by a chancellor or some similar officer and a board of trustees, and an educational portion, to be overseen by a trained educator. When you come to think the matter over there are singularly few col-

lege presidents who hold that position on account of special training. I agree also as to the unit of organization consisting of the school or department, that being the natural and logical unit. I also agree in the main with the machinery proposed in paragraph (4). The only inadvisable thing, to my mind, would be the constitution of a permanent board of advisers—if you mean it to be permanent. I would add that it might be wise to set a time limit upon the deanships—or directorships—whatever you care to call them. Personally, I doubt very seriously whether a single individual should be the controlling force in a department for more than ten years. Your fifth section, which proposes the senate and the plenums, I think is also desirable. I assume that this senate and the plenums would legislate regarding the educational policy rather than regarding the financial policy.

I heartily approve of your scheme for university control. In our university, as in others, the head of a department has altogether too much power—or uses it too arbitrarily. In fact, members of the faculty scarcely dare to oppose his plans or to vote against his reelection, for fear of reprisals, unjust discriminations, etc. Thus a president or head of a department may become a sort of dictator, or like a political “boss.”

Your reprint is a very moderate statement of the evils arising from the present system of college and university control. The worst of these evils is probably its discouraging and deterrent effect upon the men exercising the teaching functions in this class of institutions. And if this system continues without essential modifications, this form of its evil results is likely to grow with constantly accelerating rapidity. Self-respecting and gifted and independent men will not choose a career which may at any time be cut short or even totally ruined by the caprices of a presidential “boss.” For myself, and much as I love and highly as I prize the office of the teacher, I should hesitate long before accepting, were I again young and asked, under the changed

conditions, to enter the life of a college or university professor. As in all similar cases, the remedy is by no means so clear as are the evils demanding a remedy. I am inclined to think that the details of any change of plan would need to differ in different institutions. Certainly they could not be precisely the same for the private and the state institution. And in both cases, care would not be of small importance to avoid changing the benevolent despot for the uncontrolled mob. It would seem also that some means should be devised for placing the control of instruction and the control of finances in largely different hands, while securing frank and cordial intercourse between the two.

SCIENTIFIC BOOKS

The Biology of the Seasons. By J. ARTHUR THOMSON. Illustrated by WILLIAM SMITH. New York, Henry Holt and Company. 1911.

The Natural History and Antiquities of Selborne, in the County of Southampton. By GILBERT WHITE. With illustrations in color by GEORGE EDWARD COLLINS, R.B.A. London, Macmillan & Company. 1911.

It is worth while to consider these two books together, for resemblances and contrasts. They are typical of the centuries to which they belong, of the old and the new in natural history. Professor Thomson points this out, in his introductory chapter. “The older naturalists—before Darwin’s day—made many careful pictures of the life of plants and animals as it is lived in nature. The indefatigable patience, the keen observation and the sympathetic insight of many of these pre-Darwinian naturalists must remain as models to which in these later days, with improved methods, we try to approximate. Gilbert White’s ‘Selborne,’ above all, remains ever-green. But the old records are for the most part contributions to Natural History rather than to Biology. To most of their authors there was wanting the biological key which Darwin first taught men to use.” But in post-Darwinian writings “biological ideas have become dominant; analysis has become more penetrating; the pictures have a broader

perspective and a deeper insight." In the books before us, however, there is a contrast in the attitude toward the reader as well as toward the subject. Listen to Gilbert White: "If the writer should at all appear to have induced any of his readers to pay a more ready attention to the wonders of the Creation, too frequently overlooked as common occurrences; or if he should by any means, through his researches, have lent a helping hand towards the enlargement of the boundaries of historical and topographical knowledge; or if he should have thrown some small light upon ancient customs and manners, and especially on those that were monastic, his purpose will be fully answered." Simplicity and humility enough, but the offering consists of his own "researches," presented in the hope of somewhat enlarging the bounds of human knowledge. Now Professor Thomson: "That the method of seasonal biological study is educationally sound is best proved by experiment. But it is perhaps enough to ask the simple question: *What kind of scientific lore concerning living creatures would we most naturally teach our children in spring?*" The attitude is pedagogical throughout: the author has come to instruct—as pleasantly and interestingly as may be, but never forgetting that he is a teacher. The book does not set forth the "researches" of the writer, or, if doing so, makes little of them; it is a contribution to pedagogy, based on compiled materials of every kind. There is nothing of the artless art of Gilbert White, nor indeed (in spite of Selbornian imitators) is such a thing quite possible in this sophisticated age.

All things considered, Professor Thomson's book is a charming example of popular scientific writing, and we would recommend it to those who have some knowledge of the matters whereof it treats. The other day I took occasion to read one of the chapters (The Tale of Tadpoles) to a large university class in biology, and in so doing came to highly appreciate its merits, and at the same time notice what seemed to be its faults. It is extremely suggestive, so that all along the line one is tempted to interject new arguments and facts.

The whole book is just a little uncritical, the author having a field so wide that he can not quite master all the details, so that at times he takes little doubtful data on trust, and at others is perhaps led somewhat astray by his own rhetoric. This must be the fate of all popular writers and teachers, indeed of all university professors. As one of our most brilliant researchers and teachers put it in conversation recently, there is always this dilemma: if you make yourself quite clear and strive to be perfectly logical, you do it at the expense of some of the truth, because in dealing with biological matters you are never really free from difficulties and uncertainties. If you go to the other extreme, you merely produce confusion. Substantially, the method so excellently typified by Professor Thomson's writings is abundantly justified and sufficiently accurate, but critical readers will always wish that some things had been stated rather differently.

Another fault in the book reviewed is, I think, an undue tendency to use words which are not likely to be understood by the general reader. Even in the reading just mentioned, to a more or less instructed class, I found myself frequently translating. Against this objection must be set the undeniable fact that the author's rich vocabulary enables him to state things more accurately and briefly than would be possible were he to use only the poor English of the street.

There still remains the question whether popular science, as presented to-day by Professor Thomson and a number of other eminent men, has not swung too far away from the standpoint of Gilbert White. Is there not some danger of becoming too professional, too pedagogical? Is it too much to say that we can not have a real diffusion of culture in these matters until we have more of the spirit of the amateur?

The new edition of "Selborne" has a most attractive appearance. It is reprinted from the original without any alterations or annotations; there is not even an editorial note. The numerous colored plates are pleasing, yet I think not wholly satisfactory. In many the

outlines are too hard and the colors not quite true; there is too much of the mannerism of the artist. The colored plates in Professor Thomson's book also seem to me criticizable; they look a little out of focus, as it were—much as things look to the present writer when he has mislaid his glasses.

On the chance that some of our active workers in genetics have not recently read their "Selborne," it may be worth while to quote the following pertinent information: "One thing is very remarkable as to the sheep: from the westward till you get to the river Adur all the flocks have horns, and smooth white faces, and white legs; and a hornless sheep is rarely to be seen: but as soon as you pass that river eastward, and mount Beeding-hill, all the flocks at once become hornless, or, as they call them, poll-sheep; and have moreover black faces with a white tuft of wool on their foreheads, and speckled and spotted legs: so that you would think that the flocks of Laban were pasturing on one side of the stream, and the variegated breed of his son-in-law Jacob were cantoned along on the other. And this diversity holds good respectively on each side from the valley of Bramber and Beeding to the eastward, and westward all the whole length of the downs. If you talk with the shepherds on this subject, they tell you that the case has been so from time immemorial, and smile at your simplicity if you ask them whether the situation of these two different breeds might not be reversed. However, an intelligent friend of mine near Chichester is determined to try the experiment; and has this autumn [1773], at the hazard of being laughed at, introduced a parcel of black-faced hornless rams among his horned western ewes. The black-faced poll-sheep have the shortest legs and the finest wool."

UNIVERSITY OF COLORADO

THE HINDU-ARABIC NUMERALS

IN a recent number of SCIENCE I ventured to assert the correctness of the statement that our present decimal place system with the zero

¹ January 5, 1912.

is of Hindu origin. The veteran historian of mathematics, Moritz Cantor, makes substantially the same assertion in the latest edition (1907) of the first volume of his "Vorlesungen über Geschichte der Mathematik," p. 608. He says, referring to the use of words with place value.²

This kind of conscious juggling with the notions of positional arithmetic together with the zero, is most easily explained in the home of these notions, which (home) for us is India and this we may affirm even if there is question of a second home. We mean if both notions were born in Babylon, of which there is great probability, and were carried over into India in a very undeveloped state.

We may add that neither Cantor nor any other has yet presented any historical evidence that these ideas were carried over to India from Babylon. Eneström, the editor of the *Bibliotheca Mathematica*, a journal devoted to the history of mathematics, has recently³ supported the view that the Babylonian arithmetic is not of the same nature as our system. The Babylonians did not use the zero, so far as we know, with the same notion of place value for purposes of computation as in the Hindu system. The Babylonian multiplication tables published by Hilprecht which include tables of 1,800 times various numbers are an evidence of this fact. In a fully developed sexagesimal (60) system this table would be replaced by the table of thirty times the corresponding numbers, since 1,800 equals 30 times the unit of higher order, 60. Furthermore, the Babylonian system was not adapted for computation because of the mixture of decimal and sexagesimal systems and further because of the large base, 60.

Recently another early document referring to the Hindu numerals has been published. This document is of prime importance because, being written in 662 A.D., it antedates by more than two centuries the earliest known appearance in the ninth century of the numerals in Europe. The probability is, too, that the

² See Smith-Karpinski, "The Hindu-Arabic Numerals," p. 39, for an explanation of this system.

³ *Bibliotheca Mathematica*, Vol. XI. (3), 1911, p. 331.

numerals were fully developed in India not much more than two centuries before this time. We are thus brought very close to the time of the origin of the powerful symbols which we use for computation. Further, the passage is of interest because it explicitly mentions the Babylonian contributions to astronomy and we must conclude that if the writer at that early date had known of any connection between the Babylonian number system and the Hindu he would have mentioned it. The passage in question is presented by M. F. Nau in some notes on Syrian astronomy.* M. Nau quotes from the writings of one Severus Sebokt, bishop of the monastery at Quennesra, on the Euphrates, near Diarbekr. This Sebokt was famous in a literary way and made his monastery a center of Greek learning. He himself was originally from Nisibin towards India, and it is not beyond the bounds of probability that there he came into contact with the learning of the Hindus.

Sebokt claimed for the Syrians the invention of astronomy. He stated that the Greeks went to school to the Chaldeans of Babylonia and these, he adds, are Syrians. This statement of Sebokt's is supported by the most recent investigations in the history of the development of science. An interesting article on this subject was published by F. Cumont, entitled "Babylon und die griechische Astronomie."[†] Sebokt concludes that science is not the peculiar property of the Greeks, but rather open to all men.

The subsequent passage contains the reference to the numerals and I translate from the French translation given by M. Nau:

I omit now to speak of the science of the Hindus, who are not Syrians, of their subtle discoveries in this science of astronomy—(discoveries) which are more ingenious than those of the Greeks and even of the Babylonians—and of the easy method of their calculations and of their computa-

tion which surpasses words. I mean that made with nine symbols. If those who believe that they have arrived at the limits of science because they speak Greek had known these things, they might perhaps have been persuaded, even though a little late, that there are others who know something, not only the Greeks, but even people of a different language.

SPECIAL ARTICLES

THE SOURCE OF THE CURRENT OF INJURY

WHEN we connect calomel electrodes filled with KCl solutions of the same concentration with the uninjured skin and an injured spot of an apple, respectively, we notice a potential difference from between 40 to 100 millivolts, the injured spot of the apple being negative to the uninjured spot. We have made experiments which indicate that the so-called current of injury is due to a difference of potential which exists on the inside of the skin of the apple probably at the limit between the skin and an adjacent layer of cells, the latter being negative to the former. The proof for this statement is found in the following facts.

1. When we form a cell of the type

$n/10$ KCl		Apple		$n/10$ KCl
uninjured				injured
side				side

the E.M.F. remains the same no matter how deep a hole we make into the apple. As soon, however, as the $n/10$ KCl approaches the inner surface of the apple the E.M.F. suddenly becomes smaller and finally disappears.

This is not due to an injury of the skin itself, since a change in the concentration on the outer surface of the skin still gives the same change in E.M.F. as in an intact apple. The disappearance of the "current of injury" when the salt solution reaches the inner surface of the membrane of the apple is therefore due to the disarrangement or destruction of a specific layer on the inside of the surface film of the apple.

2. By pressing the surface of an apple with a finger we can destroy the adjacent layer on the inside of the skin without injuring the

* *Journal asiatique*, Vol. 16 (10th series), 1910, pp. 225-227.

† *Neue Jahrbücher f. das klass. Altertum, Gesch. und deutsche Literatur und f. Pädagogik*, 1911, Vol. 27-28, pp. 1-10.

latter. This can again be proved by measuring the influence of the change of concentration of a salt solution on that outer surface, which is exactly the same as it was before the pressure was applied. If, however, we connect this part of the skin and an intact part of the skin with a pair of calomel electrodes filled with a KCl solution of the same concentration, we get an E.M.F. of the same order of magnitude and the same sign, as if the skin at the pressed spot had been removed. This experiment, which is very striking, indicates also that the current of injury is due to the existence of a potential difference at the inner surface of the skin of the apple which depends upon the integrity of a definite structure.

3. An attempt to account for the nature of this E.M.F. led to the discovery that salts and acid, if applied in the same concentration to the outside surface of an apple, give rise to differences of potential of the same order of magnitude as found in the current of injury. The E.M.F. of the cell

$$\begin{array}{l} n/10 \text{ NaCl} \mid \text{uninjured apple} \mid n/1,000 \text{ NaCl} \mid \\ \qquad \qquad \qquad n/10 \text{ NaCl} \quad \quad \quad \text{(I.)} \\ \text{is greater than that of the following cell} \\ n/10 \text{ NaCl} \mid \text{uninjured apple} \mid n/1,000 \text{ HCl} \mid \\ \qquad \qquad \qquad n/10 \text{ NaCl} \quad \quad \quad \text{(II.)} \end{array}$$

In (I.) the E.M.F. was .088 volt, in (II.) .038 volt.

4. Since this difference is of the order of magnitude of that found in the current of injury, it was natural to test the action of the juice pressed out of the apple. Its conductivity was found to be $K_{10} = .00226$. This would correspond to a concentration of $n/58$ if the electrolyte contained in the sap were KCl, or $n/170$ if it were HCl. The apple juice contains a considerable amount of malic acid. Nevertheless it does not have the negative effect characteristic of the acid. If the negative potential on the inside of the skin is due to a layer of acid it must differ in its action from the sap pressed out from the apple.

These experiments indicate that the current of injury of the apple is due to a potential difference at the inner limit of the skin or

membrane; and that this potential difference depends upon the integrity of a preformed structure. This structure may give rise to the formation of a film of an acid but this is hypothetical.

Our observations prove that Hermann's alteration theory of the current of injury can not be correct. This theory assumes that the difference of potential exists at the injured surface, while the experiments mentioned here show that the seat of the potential difference is, at least for the apple, not at the seat of the lesion, but at the inner limit of the intact skin or membrane and its intact adjacent layer. DuBois's preformation theory is confirmed, although in a different form from that which this author suggested.

SOCIETIES AND ACADEMIES

THE BIOLOGICAL SOCIETY OF WASHINGTON

THE 498th regular meeting of the society was held in the assembly hall of the Cosmos Club on April 13, 1912, with President Nelson in the chair.

Under the head of General Notes, Dr. B. W. Evermann exhibited dyed and undyed skins of fur seals from the Pribilof Islands, and made remarks on the commercial classification of skins and on the aims of the Bureau of Fisheries regarding the fur-seal industry.

The paper of the evening was by Mr. Chas. Sheldon on "Winter Animal Life about the Base of Mt. McKinley." Mr. Sheldon gave an interesting account of his experiences with the birds and mammals of the Mt. McKinley region during the winter of 1907-08, describing in detail the food and habits of the Alaska jays, the mallard ducks, which were found wintering where local conditions favored open water and sufficient food, the lynx, conies, foxes, caribou, moose and sheep. Mr. Sheldon's lecture was admirably illustrated with numerous lantern slides, showing his cabin, general and detailed views of the country and long- and short-range snap shots of all the larger animals of the region.

THE 499th regular meeting of the society was held in the assembly hall of the Cosmos Club on

April 27, 1912, with President Nelson in the chair.

Three papers were presented:

Are Rabbits Rodents? J. W. GIDLEY. (To appear in *SCIENCE* shortly.)

Remarks on the Skeleton of the Dinosaur, Stegosaurus: C. W. GILMORE.

The type specimen of *Stegosaurus stenops* Marsh in the U. S. National Museum is the most complete skeleton of the genus that has yet been discovered, and the recent assembling of the large blocks of sandstone which contain this fossil enabled Mr. Gilmore to discuss several points in its anatomy. Especially attention was given to the position and arrangement of the elements which comprise the dermal armor, and since this is the only individual known which gives anything like a true idea of the manner in which the armor was attached the importance of the specimen is at once apparent.

It was pointed out that there was a great diversity of opinion among vertebrate paleontologists, especially regarding the number and arrangement of the plates and spines constituting the exoskeleton. Marsh in 1891 made the first pictorial restoration of *Stegosaurus* and placed the series of flat plates (12 in number) in a single row along the median line of the neck, back and tail, with four pairs of spike-like spines near the end of the tail. Lucas in 1901 published the next restoration, and was the first to show the plates (28 in number) arranged in pairs. Later in a statement prepared under his direction the plates of opposite rows (22 in number) were made to alternate, and the spines were reduced from four to two pairs. The latest conception, as exemplified by a recently mounted skeleton in the Peabody Museum of Yale University, shows a return to the paired arrangement of the plates (28 in number) and the retention of four pairs of spines.

It was shown that specimens in the National Museum corroborated most conclusively Lucas's second interpretation, and with the exception of one or two points is entirely in accord with the evidence.

That the plates of opposite rows did alternate is shown by the way they lay embedded in the rock, and that no two of them were precisely similar in shape or dimensions.

It was demonstrated that the usual number of spike-like spines is two pairs, as shown by seven individuals, six of which are in the National Museum.

The facts relating to the dermal armor which now appear to be established from this preliminary study are:

1. That the armor of the neck, back and tail was found by two rows of erect plates, the elements of one row alternating with those of the other.
2. That the total number of plates in the two rows was not less than 22.
3. That the position of the largest plate of the series appears to be above the base of the tail, and not over the pelvis.
4. That the usual number of dermal spines on the tail is 4, arranged in two pairs.

Early Bird Migration in a Late Spring at Washington, D. C., 1912: WELLS W. COOKE.

The winter of 1911-12 was the coldest at Washington, D. C., for many years, and yet several species, notably the robin, were more common than usual, due to unusually warm weather in December.

January, February and March to the 27th were far below the normal, and yet about half of the species of birds that arrived during this period were earlier than their average date. When, however, these species were examined more carefully, it was found that those who arrived early were all species that occasionally winter as far north as Washington, and these early migrants undoubtedly represent individuals that had spent the winter in the heavily forested swamps and had been observed when they returned to open country.

The rest of the species that arrived late during this cold period were all birds that winter far to the south of Washington.

On March 28 the weather turned warm and remained above normal for a whole month. Immediately birds began to arrive from the far south that were decidedly ahead of their normal date, and in the case of some of them, earlier than the earliest previous date. This is one of the best examples of what usually happens when a cold spell begins to break. The cold had been widespread, holding the birds far south, and when the warm spell began the birds rushed north and continued their flight longer than usual until they were actually ahead of their schedule time.

Almost every species for the whole of the rest of the migratory season of 1912 at Washington, D. C., arrived earlier than their average dates.

At first glance there would seem to be opportunity, in this country, for more than one type of college and university, and if the opportunity, then the obligation and the inspiration. Historically there are two types, but under identical environmental influences they present to-day few distinguishing characters. They exhibit a phenomenon very rare and interesting in biology. While we have been speculating and searching about the origin of species by evolution, the history of the American colleges has recorded the almost complete disappearance of a species through imitation, a transmutation instead of a mutation! The endowed college, later called university, was the first type to appear on the American continent; but with the growth of the public school idea, with the outgrowth of those aristocratic remnants which the early settlers so unconsciously brought with them and so strongly exhibited, and with the immense addition to the English stock by immigration from continental Europe with its universities founded and maintained by the funds of the people, it was only natural that state universities should come into existence. For the most part they are found in those states which have nothing more tangible to connect them with the past than *traditions* of aristocracy, and at all events they prosper most, if one may judge by our usual American standards of dollars or of numbers, in the states in which the people is most thoroughly satisfied that the people can do no wrong. The future, the opportunity, of the endowed university may appear, therefore, to

be anything but bright and inspiring; but an honest examination of the circumstances of the state and the endowed universities will lead any one to rejoice in the prospects of both.

The state university is endowed with the wealth of the state; its endowment increases with the wealth of the state, automatically and without struggle. What this has already meant in certain instances is but a small fraction of what the future has in store. The wealth of the richest of the colleges of Oxford and Cambridge is poverty in comparison with the potential wealth of some of our state universities: unless and until the descendants of the people which called the university into being recall it to a condition of penury. The endowments of the state universities yield incomes the large totals of which are increased at intervals by appropriations for such specific purposes as have won popular or legislative appreciation and approval or may capture the fancy of the self-styled "practical man."

The contrast of the endowed university with all of this seeming prosperity would be disheartening to its friends if they took no account of the influence of the endowment and income. While the income of the state university may grow proportionally with its endowment, its officers and friends take nothing for granted and occupy themselves in securing this happy result. On the other hand, once sufficiently endowed to be useful, the endowed university need not struggle for money. It will never have too much if it wisely spend what it has; and if it transmutes its gold into lives of exceptional usefulness, more gold will come to it from grateful alumni and from admiring friends who would increase its opportunities for service. The endowed universities have struggled for money as desperately as those of the states, but this has

been either because they were insufficiently endowed or because their administrations, not content with usefulness, lusted after bigness also. But given a sufficient endowment, so managed that its income will be both fair and uniform, the endowed university is independent as no state university ever is: not free from duties, but free from hindrances.

What the people wants, what it pays for, it rightly insists upon having. The people goes further and says that these things all the citizens of the state should have. The people insists above all upon training for practical life. To the schools of law and of medicine, agriculture and engineering, it enthusiastically and optimistically adds courses in domestic science, poultry husbandry, cheese-making, and the rest. Has it occurred to the "practical" legislator or the "practical" voter that the establishment of courses in domestic science has been followed by a more acute stage of the servant question? Is this mere coincidence?

The people demands of its university that it be in every way useful, that, where training is impossible, at least it should give information. In response to this demand come university extension (not university elevation), summer schools, farmers' institutes, short courses and correspondence. The young American democracies provide not only a "royal road to learning," but omnibuses traveling rapidly over the road with pneumatic tires—I forbear to mention the temperature of the air which fills them. These omnibuses always take in and discharge their passengers in haste and confusion, sometimes even in darkness. They must be driven by persons capable and sometimes desirous of taking a more promising company over a less commonplace road, whence the views, forward

and perhaps even upward, may be more extended.

As part of the educational system of the state, the state university must admit all presenting a high school diploma. It can not sift, and exclude the ignorant, for there is none ignorant, as the certificates show! It can not insist that the boy who would be an engineer present himself with a usable knowledge of algebra and geometry. It is obliged to accept as a working basis the popular delusion that all subjects furnish equally good preparation for college as well as for everything else, that all study is equally informing and developing, that all students are equally fit. But in so doing, in its seeming liberality in keeping its front door apparently so wide open, it places obstacles in the way of all who would enter from any other than the conventional school. The seriousness of these obstacles is seldom apprehended by others than those who encounter them. The boy whose family has traveled, taking him with them—the son of an engineer, or a missionary of commerce or religion, for example—having attended an accredited school for too short a time to receive a certificate, or being taught in a private school or in still more private lessons quite unknown to a registrar's office, finds himself unable to enter the wide open front door of the usual college, state or endowed. Although very likely more mature and better trained, of wider as well as more definite or first-hand knowledge, of broader experience and more independent thought, he is refused admission unless, by passing examinations to which only he and his kind are subjected, he convinces the authorities that he knows almost as much as a boy from the Bean Blossom High School in Posey County.

The state universities are more or less compelled to take the products of the public schools unsifted; they can not especially

cultivate and encourage the exceptional young person; they must do mainly a wholesale business; and they are increasingly burdened with great numbers of conventionally trained mediocrities. They are necessarily organized to receive, care for, graduate and find positions for these. Thus they annually produce more teachers who will produce more students of the same mediocre sort. What this weight of numbers is may be indicated by the attendance, in round numbers, on the usual elementary course in botany at the following universities:

Wisconsin	300
Minnesota	500
Nebraska	350
Stanford	50

Botany I. at Harvard, a fairly large course (130), is not the equivalent of Botany I. at the universities above mentioned, and the corresponding course has between 40 and 50 in it. Granting the stimulation of lecturing to large numbers, what is the effect of attempting laboratory work for so many? Providing, in the winter, plant material for such numbers, organizing and directing the staff of assistants, conferring with students in this and in the more advanced courses, the head of the department and his colleagues find their time, their strength, and finally their desire, for their own researches exhausted. There is no time for reflection; every one is so busy doing that there is no opportunity for thinking; every one is working at high pressure, but is it worth while? Researches come from these laboratories, but they are not original. They are the products of the changing fashions rather than the fruit of individual effort. A glance at the programs of the national scientific societies proves that isotonic coefficients and chromosomes have been displaced by mutation, Mendelism, and plant-breeding. American

universities add annually to the "literature" of science, and in the great numbers of elementary students to be cared for I think we can all see one great reason why the contributions of promising American scientific men have reached no higher level.

Turning now to the endowed university, it is obvious that its officers need spend no time at the capitol, for its income can not there be increased; they need make no concessions in order to keep Greek from disappearing from the catalogue; they can let others wrestle with the problems of "educational psychology," "humanics" and "live stock practise" while devoting themselves to psychology, sociology and zoology. The endowed university may go its own way independent of the currents of fashion and of popular whim. It is naturally sheltered from those influences. It is only when its leaders attempt to duplicate the work of the state university that it finds itself exposed to the same influences. And when it exposes itself to these influences, it does so without the defenses of the state university.

The opportunity of the endowed university is a great one, inspiring to contemplate. It, or its *directing* administration, may determine its course, select the subjects it will teach, specialize instead of generalize, foster pure science and the arts. Whether American universities be democracies or autocracies, all or some of the officers of the endowed universities have the opportunity, and the obligation, to decide what these universities will do—whether to compete on unequal terms of wealth and of other forms of support with the state universities, to seek numbers, to strive for bigness, to submit to the fashion, to comply with the current wish: or to decide what it will attempt, what subjects it will cultivate, to teach and to investigate and to develop these to a degree unequalled else-

where; to pursue the studies of pure science, the humanities and the arts as assiduously and as devotedly as if they were themselves the keys to wealth.

The endowed universities may select their students on any basis that they will; may pick the children of the well-to-do or young people whose unprogressive parents have cruelly limited them to schooling in Latin, Greek and mathematics when they might have "taken" hygiene, civics and "vocational subjects"; may, on the other hand, welcome the exceptional as well as admitting the usual; may cultivate and encourage the best. The endowed university may as consciously and as definitely prepare for the few, for the unusual, the most original and the most stimulating student as the state university must certainly prepare for unsifted numbers.

The masses of a democracy recognize present wants more surely than they anticipate future needs. They require an immediate supply to meet an existing demand. They consider their state university to be well fulfilling its functions when it furnishes such a supply. How well it succeeds in this the fair-minded observer admiringly acknowledges. But the wholesale business of the state university limits, if it does not practically prevent, that attention to the exceptional student which may result in training a leader of his generation, a seer who, divining the future needs of the state, may begin to prepare to meet them, a man who, profiting by the recorded experience of the past, may mold as well as meet conditions. The training of workers is the duty of the state and of the endowed university; the training of leaders is the privilege more especially of the endowed universities for the reasons I have given. How well some of the endowed universities have apprehended and lived up to this privilege the records of

Harvard and Yale, of Columbia and Princeton, and of Johns Hopkins *sui generis*, fully attest. May they not neglect their privilege and abandon their peculiar work!

What the endowed universities have successfully and naturally done for generations some of the state universities are now attempting against opposition of every sort. How successful, judging only by the test of quality, not of numbers, these universities will be in producing statesmen, jurists, economists and explorers in the fields of pure science, it is still too early to say. To recognize these in embryo, to train these young people for their distinctive careers, is easier for the endowed university than for that of the state, provided only that the endowed university, realizing its privilege and confining its efforts to its special field, does its duty. This, I take it, is the special service which the endowed university can perform, its reason for existence by the side of the university of the state, not copying it, not competing with it, but supplementing it, training leaders.

Their numbers, their courses, limited by their incomes, the endowed universities may remain small with no sense of shame or of failure. The Rookwood Pottery is smaller than many a brick-yard, yet all are needed, all are useful. In the space and quiet of "the yard" or of the quadrangle there is time for reflection, for review, which in the past have led to real contributions to knowledge or to thought. The scholar's life and the scholar's product, not fostered by the conditions of office or consulting-room, may continue if the endowed universities recognize and cherish their high privilege, serving the state and the world with their own peculiar talent, not copying the form or attempting the task of their huge neighbors, not seeing in them rivals but friends. May these allies, real-

izing their privileges, their distinctive opportunities, win the glories of their recognized usefulnesses!

GEORGE J. PEIRCE

LELAND STANFORD JUNIOR UNIVERSITY

RESEARCH ON THE SMOKE PROBLEM AT
THE DEPARTMENT OF INDUSTRIAL
RESEARCH OF THE UNIVERSITY
OF PITTSBURGH

SMOKE exists to a greater or less extent in every city where soft coal is burned. The world at large has not, up to the past few years, regarded it as a waste. It has been considered synonymous with prosperity. Its right to cloud the heavens has been traditional. The enormity of this evil is fast being forced upon the public attention so that the manner in which it is being combated in the big metropolitan centers affords an interesting and profitable subject for study.

Strange to relate, when one stops to consider the breadth of interest and importance of this problem, together with the fact that so many thousands have worked on its various phases, and that so much has been written and is being written on the subject, still no coordinated effort of one group of men has been made to undertake a scientific study of the problem as a whole. One of Pittsburgh's most public-spirited citizens, a man devoted to the city's welfare, recognizing this fact, has established a fellowship of \$12,000 per year with the department of industrial research of the University of Pittsburgh for the scientific investigation of this problem.

We have an unpretentious laboratory, designated as the "smoke house," a small, fireproof building, 18 feet wide and 30 feet long, which is situated at a sufficient distance from the main laboratory, so that the smoke in quantities as great as we may need in our work can be made without interfering with the other researches being carried on. In this building there is a furnace, so constructed that it is possible, by varying conditions, to get any kind of coal smoke. This statement may, perhaps, appear peculiar to those who have always considered smoke as just smoke, but our studies

of this subject reveal new properties continually. There are differences in the physical state as well as in the amounts of tar, carbon, ash, etc., in smoke made from different kinds of coal under different conditions of temperature, etc. By means of fans and motors, the smoke can be conducted to various parts of the building, where it can be used for experimental purposes in any manner desired. It is here that the physical and chemical studies are being conducted with the object of learning more definitely just what the various properties of soft coal smoke are, and endeavoring to ascertain new properties which will be of aid in the abolition of the smoke itself.

It is a well-known fact that it is possible to prevent smoke with the accompanying economy of fuel and that there are many forms of furnaces constructed which can be operated with ideal results. The obtaining of men sufficiently intelligent for their proper operation is, however, a problem difficult of solution, for the wages are small and employment far from pleasant. One of the chief aims of our experimental work is, then, to find a means of making the man in the boiler room perform his duty in the best possible manner. A mechanism is being devised, which is simple, practical and "fool-proof," that will automatically warn the stoker in the boiler room that the smoke his fire is making is in excess of the law.

Inquiry is being instituted, in the most accurate manner possible, into the true increase in the cost of living due to the damage done by smoke to the property of the residents of this smoky district. Special stress will be laid upon this portion of the investigation because of the fact that while those who have made Pittsburgh smoky may be large losers by the neglect, they are in all probability not the greatest. Among the list of sufferers upon which the burden falls, we may include dwellings, hotels, hospitals, picture galleries, museums, office buildings, banks, libraries and stores, both wholesale and retail.

The relation of smoke to the health of the residents of a smoky district is one worthy of careful consideration, and one which we hope

to be able to put on a more scientific basis than the present.

It is a well-known fact that the lungs of a person dwelling in a smoky atmosphere become coated with soot particles. Does this make him more susceptible to consumption? The question has been answered both negatively and positively by different authorities. From a thorough examination it would appear that Pittsburgh did not have as much consumption as other cities similarly located, where there is much less smoke. Within the corporate limits of the city there is more consumption in the better residence portions, where there is less smoke and dirt than in the more congested district where smoke abounds. On the other hand, catarrh, pneumonia and other so-called "bad air" diseases are very prevalent, due to the irritation caused by the smoke particles. Furthermore, it has been said by some that because of the mucus swallowed in these diseases, stomach trouble is thus indirectly caused by smoke. The eyes are not immune, either. Eye specialists say that the busiest time is after a heavy fog accompanied by smoke.

From the side of aesthetics and the city beautiful, we must take up the effect of coal smoke on buildings and on plants. The botanical side of the question is one of special scientific interest, for while the relation of plants to smelter fumes, etc., has received considerable attention, little if anything seems to have been accomplished or even attempted from the standpoint of the carbon with the accompanying tar-containing phenol and other compounds of a similar nature. It may be of interest to state in this connection that I have found as high as 44 per cent. tar in samples of soot examined. Knowing this, it can well be understood that carbon smoke might have a very injurious effect on vegetation, more especially in spring, when the new leaves are appearing and things being tender are much more readily affected by the toxic action of the soot and accompanying substances.

The meteorological aspect of the smoke problem is being considered. This part of the investigation will, for the greater part, consist

of the application to our local conditions of the methods used in other places.

The smoke problem is not an easy one to handle. There are many obstacles to overcome and many prejudices to set right. Without power to act, knowledge in itself would be of little avail. Therefore the legal aspect of the situation will form no small part of our investigation.

In brief, then, we have in this research the twofold object of scientifically ascertaining the true economic status of the smoke problem in all its phases and the devising of ways and means of making the smokeless combustion of soft coal the rule rather than the exception.

R. C. BENNER

UNIVERSITY OF PITTSBURGH

CANCER RESEARCH

DURING the past winter important developments in the field of cancer research have occurred in New York City which have hitherto escaped public notice. By the addition of \$100,000 to the endowment fund of the General Memorial Hospital to be used for the maintenance of 20 free beds for cancer patients, a well-known scientific man has provided the staff of the Collis P. Huntington Fund for Cancer Research with greatly increased facility for the study and treatment of cancer in the human being.

The General Memorial Hospital for the Treatment of Cancer and Allied Diseases was originally chartered for the study and treatment of cancer but at the time of its foundation, cancer had little interest to any one but the surgeon. To-day the wide field of research opened up by the experimental study of cancer is too costly to be undertaken by any hospital without an unusually liberal endowment; and it may be said that no hospital in New York possesses to-day an adequate endowment for this purpose.

The General Memorial Hospital has enjoyed the support of the Huntington Fund for Cancer Research founded by Mrs. C. P. Huntington, since 1902. The trustees of this fund, of which the late Dr. W. T. Bull was chairman, placed the fund at the disposal of

Cornell University Medical College in whose laboratories systematic research has been conducted as far as the income of the fund and the resources of the university would permit. Under this arrangement three volumes of studies have been published relating chiefly to experimental observations on lower animals, but the work has been limited in scope by the lack of hospital facilities, and a close cooperation between the laboratories and the hospital wards.

The recent donor, himself a scientist of international reputation, a supporter of cancer research, both here and abroad, and fully acquainted with the proper organization of such work, determined to supply the needs of the Huntington-Cornell staff, and by his liberality has opened a portion of the General Memorial Hospital to cancer research under very favorable auspices. In addition to the endowment of 20 beds, chemical and pathological laboratories are now being constructed in the hospital and a complete X-ray and Radium department is being provided for the early diagnosis and treatment of the disease.

This latest addition to the resources of cancer research is significant in several respects. It is a noteworthy instance of the discriminating support of science by a scientific man who knows exactly what his gift may accomplish. It supplies for the first time in New York City the opportunity for men trained by a university in many branches of medical science to study this disease at the bedside. It enables the pioneer institution founded in the city for the care of malignant disease at last to enter in earnest into the field for which it was established. Incidentally it points out a way for a most effective use of much larger endowments than are even now available. Although a considerable capital is represented in the various branches of this institution, clinical cancer research has been found to be extremely costly, and even the present endowment fails to provide all the important necessities in the work.

Not the least gratifying result is that New York City is now provided with an institution similar to those recently established in

London, Berlin, Heidelberg and Paris, abroad, as well as in Buffalo, St. Louis and Boston, here, and that this institution has the advantage of having an organization of men thoroughly trained in cancer research work, which it has taken ten years to develop and bring together.

The problem of cancer is the most serious of all the problems that confront the medical profession to-day. The steady increase of the disease baffling all efforts to discover the cause or a means of controlling it has attracted the leading minds in medicine to the field of cancer research. The only hope of a solution of this great problem is by bringing to bear upon the problem, the combined efforts of every department of medical science and by having the closest affiliation between the cancer wards and the scientific laboratories of a great university. W. B. C.

THE NATIONAL ARGENTINE OBSERVATORY

UPON the recommendation of the Minister of Public Instruction the Argentine Congress has provided in its budget for 1912 a 5 foot reflecting telescope for the National Observatory at Córdoba.

It is expected to locate this telescope in the mountains to the west of and close to Córdoba where preliminary investigations have already been made and the meteorological conditions found to be good.

The program of work for this telescope comprises photographs and other investigations of the nebulae and clusters of the southern sky, in continuation of similar work in the northern sky; photographic observations of comets, faint satellites, etc.; stellar parallax; observations of special regions of the sky; spectrographic observations with high and low dispersion and in the line of sight.

C. D. PERRINE

OBSERVATORIO NACIONAL ARGENTINO,
CÓRDOBA, May 11, 1912

AN INTERNATIONAL CONGRESS OF ANTHROPOLOGY

AT an International Conference called by the Royal Anthropological Institute and held

June 4 in the rooms of the institute, London, immediately following the sessions of the International Congress of Americanists, it was voted to organize an international congress of the anthropological sciences, which shall either include several existing congresses or work in affiliation with them. The congresses which it is hoped may become a part of the projected congress are Congrès International d'Anthropologie et d'Archéologie Préhistoriques, International Congress of Anthropology, Congrès Internationaux d'Ethnographie, International Folk-Lore Congresses and International Congress of Americanists. The organizing committee appointed by Dr. A. P. Maudslay, president of the conference, consists of the following: Maudslay (*ex officio*), chairman, R. R. Marrett (Oxford), secretary, Hrdlička, Boas, Krämer, Capitan, Heger, Duckworth, Waxweiler, Lafone Quevedo, van Panhuys. This committee met at the close of the conference and decided that a congress should not be held before 1915 (if then). In the meantime a general committee is being constituted by gradually adding names to the organizing committee; and sub-committees are being formed to establish harmonious relations with the various existing international congresses.

GEORGE GRANT MACCURDY

HONORARY DEGREES IN SCIENCE

THE degrees conferred by Harvard University at its recent commencement on men of science and words used by President Lowell are as follows:

Master of arts: Charles Francis Stokes, surgeon for sailors in peace and war, on sea and land, on battleships in the west and the east and around the world; professor of surgery, director of hospitals, Surgeon-General of the Navy. Doctor of science: Frederick Forebheimer, who in his practise, by his teaching, and with his pen, has contributed to the marvellous advance of medicine in our day; a man in the judgment of his peers worthy to preside over the Association of American Physicians; Carlos de la Torre y Huerta, statesman and naturalist; first in his knowledge of the molluscs of the Gulf; discoverer of fossils who has revolutionized the geologic history of Cuba; Frederick Cheever Shattuck, a teacher of medicine, pungent

and incisive; a practitioner with the insight that makes a physician great, and with a strong man's sympathy that has brought comfort and courage to countless sufferers; Benjamin Osgood Peirce, physicist and mathematician, by whose skill in experiment and calculation intricate problems in heat and magnetism have been solved; a man of science ignorant only of his own deserts. Doctor of laws: George Washington Goethals, a soldier who has set a standard for the conduct of civic works; an administrator who has maintained security and order among a multitude of workmen in the tropics; an engineer who is completing the vast design of uniting two oceans through a peak in Darien.

The honorary degree of doctor of laws was conferred by Western Reserve University, at commencement, upon Dr. P. P. Claxton, United States Commissioner of Education; Dr. G. A. Gordon, pastor of the Old South Church, Boston, and Dr. T. C. Mendenhall. Dr. Mendenhall was presented by Dr. Frank Perkins Whitman, professor of physics, who said:

Mr. President: I present to you, that he may receive at your hands the degree of doctor of laws, Thomas Corwin Mendenhall, teacher, investigator, administrator, professor of physics, but chiefly leader and inspirer of youth in this state, and the Imperial University of Japan; effective interpreter of nature and her laws; president of two notable scientific schools; head of a great government department; leader or collaborator in many scientific undertakings of the United States. Though prevented in youth by circumstances, not according to his desire, from entering regularly on her courses of study, Professor Mendenhall is no stranger to Western Reserve, for at the old college in Hudson he found a congenial academic atmosphere, and the inspiration of high scholarly ideals, as a special student with Professor Charles A. Young. To-day Western Reserve University cordially receives him into the company of her graduates, at the summit of a career of which in the day of small beginnings she is happy to have had some part in laying the foundation.

Among recipients of the doctorate of laws from the University of Pennsylvania are the following: Joseph Swain, president of Swarthmore College, and the orator of the day; Louis A. Duhring, professor emeritus of dermatol-

ogy and honorary curator of the dermatological collections of the University of Pennsylvania; James Tyson, emeritus professor of medicine at the University of Pennsylvania, and John Grier Hibben, president of Princeton University.

At its recent commencement Northwestern University conferred the degree of doctor of science on Dr. Henry Smith Carhart, emeritus professor in the University of Michigan and from 1872 to 1886 professor of physics in Northwestern University.

Brown University has conferred the honorary degree of doctor of science on Professor W. J. Hussey, director of the observatory of the University of Michigan.

SCIENTIFIC NOTES AND NEWS

THE board of scientific directors of the Rockefeller Institute for Medical Research announces the following appointments and promotions: Alexis Carrel (experimental surgery) has been promoted to the rank of member of the institute. The following associates have been made associate members for a term of three years: Peyton Rous (pathology and bacteriology), Donald Dexter Van Slyke (chemistry), Walter Abraham Jacobs (chemistry) and Frank Watts Bancroft (experimental biology). The following assistants have been made associates: Paul Franklin Clark (pathology and bacteriology), Richard Vanderhorst Lamar (pathology and bacteriology) and Har-dolph Wasteneys (experimental biology). The following new appointments are announced: Harold Lindsay Amoss (assistant in pathology), Clarence J. West (assistant in chemistry), Wolfgang Ewald (fellow in experimental biology), Francis Richard Fraser (assistant resident physician and assistant in medicine), Frederic Moir Hanes (assistant resident physician and assistant in medicine).

DR. EDGAR W. OLIVE, professor of botany in the State College of South Dakota, and state botanist, has been appointed curator in the Brooklyn Botanic Garden, to have charge of the department of public instruction, and also

of the work in plant pathology. The appointment takes effect on September 1, 1912.

CAPTAIN H. G. LYONS, F.R.S., has been appointed assistant director of the Science Museum, South Kensington.

PROFESSOR DÜRCK, until a short time ago director of the pathologic institute at Jena, has assumed the direction of the pathologic institute at Rio de Janeiro.

THE executive committee of the Entomological Society of America has named the following as additional delegates to the second International Congress of Entomology, to be held at Oxford, England, August 5 to 10, 1912: Professor Stephen A. Forbes, University of Illinois; Dr. L. O. Howard, chief, U. S. Bureau of Entomology; Dr. Wm. M. Wheeler, Harvard University; Dr. James G. Needham, Cornell University.

THE former students of Professor O. Henrici, F.R.S., who recently retired from the chair of mathematics at the City and Guilds Engineering College, have had engraved in his honor a medal to be awarded annually for proficiency in mathematics.

THE alumni and students of the School of Mines of the University of Pittsburgh have held a banquet in honor of Professor M. E. Wadsworth, the retiring dean of the school. In presenting a silver loving cup to him, Mr. Floyd Rose said: "In the four years during which Dr. Wadsworth has been with us he has become intimately associated with every student in the school. He has aided the weak, encouraged the despondent and won the affection of every one with whom he has come in contact. A more popular or more successful dean the university has never seen. From an insignificant department, he has developed the school of mines into one of the best schools of its kind in the country. It is a source of pleasure that, though he retires from teaching, he will remain with us as dean emeritus."

THE Lucy Wharton Drexel medal of the Museum of Archeology of the University of Pennsylvania has been awarded to Dr. M. Aurel Stein for his explorations in China.

THE Albert medal of the Royal Society of Arts has been awarded to the Right Hon. Lord Strathcona and Mount Royal, F.R.S., for his services in improving the railway communications, developing the resources and promoting the commerce and industry of Canada and other parts of the British empire.

DR. CHARLES J. CHAMBERLAIN, of the University of Chicago, has been elected an honorary member of the Naturforschende Gesellschaft an der Kaiserl. Universität zu Kiew, Russia. Dr. Chamberlain has just returned from Australia and South Africa, where he has been making a field study of the oriental cycads and collecting material for a detailed morphological investigation.

PROFESSOR BURTON E. LIVINGSTON is continuing his researches at the Desert Laboratory during the present summer. He is assisted by Mr. E. M. Harvey.

MR. J. T. LLOYD, assistant in limnology in Cornell University, has recently gone from Colombia, where he has been spending the past six months collecting in the summits of the Andes, to Europe, where he will spend the summer visiting fresh-water biological field stations.

HENRY HOLMES BELFIELD, dean of the technological course of the high school of the University of Chicago from 1903 to 1908, and organizer of the Chicago manual training school, of which he was director until it was merged with the university high school in 1903, died in Ann Arbor, Mich., on June 5.

THE United States Civil Service Commission announces an examination on July 24, to fill vacancies in the position of entomological assistant (male), at salaries ranging from \$1,400 to \$1,800 per annum, in the Bureau of Entomology, Department of Agriculture, Washington, D. C.

A RESEARCH laboratory is being planned for the National Jewish Hospital for Consumptives at Denver, to cost about \$100,000.

THE nineteenth International Congress of Americanists to be held in 1914 will consist

of two sessions: the first in Washington, D. C., and the second at La Paz, Bolivia.

THE Paris correspondent of the *Journal* of the American Medical Association writes that the *Journal Officiel* has recently published very discouraging statistics on the French population in 1911. In 1911, there was an excess of 34,869 deaths while the year before there was an excess of 71,418 births. This difference is due, on one side, to the diminution of births (742,114 infants reported living in 1911 against 774,390 in 1910) and, on the other side, to the increase in the number of deaths (74,011 greater in 1911 than in 1910). The deaths have been more numerous in 1911 than in 1910 in almost all the departments. In proportion to the population, the Norman departments, as in the preceding years, furnished the greatest mortality. The notable increase in the proportional number of deaths in France as compared with many other countries is because France is one of the countries in which there are the greatest number of aged people and chiefly because of the small birth-rate of recent years. Although the birth-rate is low, France is among the countries in which the number of marriages is relatively large. In 1911, 307,788 marriages were registered. The constantly increasing number of divorces reached 13,058, slightly more than in 1910. The birth-rate is low in many countries at the present time, but in no country is it so low as in France. Among the many measures suggested to check this increasing depopulation, the most recent is the proposal which M. Messimy, former minister of war, has made to the bureau of the chamber of deputies. M. Messimy believes that a premium at the birth of every child born of the same mother, reckoning from the fourth, would increase the number of births. This premium would be \$100 (500 francs), of which one half would be paid to the mother at the birth of the child and the other half deposited in the national pay-office for pensions, in order to insure her an income from it during life. The mother could, however, collect the sum at once, or devote it to assure herself a

subsequent pension, which, in this case, would naturally be much greater. In order to meet the expenses which the premium of 500 francs or subsequent annual income would involve, M. Messimy proposes either to resort, entirely or partially, to the regular budget-resources or to place a special tax on bachelors as well as on heads of families without children or having only one child.

A CIRCULAR by the National Bureau of Standards, Department of Commerce and Labor, on the measurements of length and area, including thermal expansion, is in press. It supersedes a similar circular issued July 1, 1909. The new regulations and fees will go into effect May 1. The bureau gives notice that it will be glad to cooperate with investigators, manufacturers and others, not only in executing tests of the highest precision, but also, on request, in furnishing any information at its disposal concerning methods of measurement, the relations among and the legal status of units, the requirements that accurate standards should fulfill, and the design and construction of special apparatus. The bureau will not accept for tests standards and apparatus likely to change excessively or that can be checked with ordinary facilities, such as poorly divided scales or scales graduated on wood, celluloid or paper. A certain minimum of quality will be insisted upon to admit to test. The circular defines the conditions influencing the dimensions of bodies and also describes the fundamental unit of length. It refers to the interrelation of secondary and special units of length and area, with tables of equivalents added, and also devotes some space to a description of national prototype meters, of which it has accurate copies. For the routine work of testing use is made of secondary or working standards whose values are carefully determined by comparison with the bureau's prototype meter from time to time to detect any possible changes. These working standards include multiples and submultiples of the meter and of the yard. Methods of comparison of length standards are outlined and the classification

and nature of tests are defined. The circular concludes with general instructions to applicants for tests and gives the schedule of fees for reference standards, working standards, commercial standards, metal tapes, contact standards, precision screws and calipers, areas and area measuring instruments and thermal expansion of materials. For educational and scientific institutions and societies a discount of 50 per cent. will be allowed on all tests under the schedules stated.

UNIVERSITY AND EDUCATIONAL NEWS

SIR JULIUS WERNHER bequeathed £250,000 to the treasurer of the Union of South Africa for the purpose of assisting in building, and, if sufficient, partly endowing, a university at Groote Schuur, near Cape Town, and £100,000 to the Imperial College of Science and Technology, South Kensington, together with twelfth parts of his residuary estate, but not exceeding £50,000.

PROFESSOR NEWTON H. WINCHELL, of Minneapolis, for many years state geologist of the Minnesota Geological and Natural History Survey, has presented his geological library to the University of Minnesota. This library is probably one of the best private collections of geological literature in this country and was built up through the years when Professor Winchell, as editor of the *American Geologist*, had unusual opportunities for obtaining the earlier serial and regional reports of this and foreign countries. Many of its volumes are priceless. The library is now being installed in the department of geology at the University of Minnesota and will be known as the "Winchell Library of Geology," to which hereafter donations and exchanges should be addressed.

DR. EUGENE L. OPIE, professor of pathology in Washington University, has been appointed dean of the medical school to succeed Dr. George Dock, relieved of this duty at his own request.

SAMUEL N. SPRING, forester of Connecticut and lecturer in the Yale Forest School, has been appointed professor of forestry in the

New York State College of Agriculture, Cornell University.

DR. J. W. JENKS, professor of political economy at Cornell University since 1891, will become professor of government and public administration and director of political studies in the School of Commerce, Accounts and Finance of New York University.

DEAN WALTER R. CRANE, of the School of Mines, Pennsylvania State College, has been granted a year's leave of absence and left June 13 to spend the coming year in the study of the coal fields of Alaska and the northwest. Dr. Elwood S. Moore, professor of geology, will be acting dean during Dr. Crane's absence. Assistant Professor Thomas C. Brown, department of geology, has resigned to accept a similar position at Bryn Mawr College. Mr. H. N. Eaton, instructor in geology and petrography, University of Pittsburgh, has been appointed to succeed him. Associate Professor of Mining William M. Weigel has resigned to accept the position of general superintendent of the North American Smelting Company, Ltd., Kingston, Ontario, Canada. Hugh D. Pallister, instructor in metallurgy, has been appointed to succeed Professor Weigel with the title of assistant professor of mining. Harry B. Northrup and William A. Royce have been promoted from assistants to instructors in mining. Carroll A. Garner has been appointed instructor in mining.

THE following appointments have been made for the coming year in the North Carolina College of Agriculture and Mechanic Arts: instructor in chemistry, J. W. Nowell, A.B. (Wake Forest), Ph.D. (Hopkins), and F. B. Sherwood, B.S. (North Carolina College).

At the Indiana University the following promotions from assistant professorships to associate professorships have been made: Robert D. Carmichael, in mathematics; Melvin E. Haggerty, in psychology; Clarence E. May and Frank C. Mathers, in chemistry; Fernandus Payne, in zoology.

DR. DANIEL STARCH has been promoted to the rank of assistant professor of psychology at the University of Wisconsin.

DR. JOHN SATTERLY has been appointed lecturer in physics at the University of Toronto.

MISS CARRIE M. DERICK, who has been acting-head of the department of botany at McGill University, Montreal, for two years, has been appointed professor of morphological botany. She is the first woman who has been made a full professor in a Canadian university.

DISCUSSION AND CORRESPONDENCE

OBlique ORIENTATION OF MAPS AND HALF-TONES

It is a well-nigh universal custom of cartographers, in constructing maps on the orthogonal, conic, or any other projection with converging meridians, to draw the central meridian straight in each case and place it parallel to the lateral edges of the paper, except when dealing with small areas considerably elongated in a direction oblique to the meridians, such as Manhattan Island or some portions of the coast. In recent years, however, there have appeared in scientific literature quite a number of sketch-maps of the eastern United States with the central meridian inclined several degrees to the perpendicular, without any apology or explanation. One of the latest examples is the map of the chestnut-bark disease on page 420 of *SCIENCE* for March 15, 1912.

Evidently the persons who have submitted such maps for publication simply took base-maps of the whole United States and cut them parallel to the edges without taking the trouble to orient them in accordance with the cartographic principle above mentioned, and the result is rather offensive to the eye of the geographer. In the case mentioned less than half the original base-map was used, with the result that even the western edge of the published map is inclined a little to the left, and the central meridian is about 10° out of plumb. (There is a correctly oriented map on page 406 of the same issue of *SCIENCE*.)

Of course if the meridians were shown on such maps their curvature (in some of the projections commonly employed) would still reveal the fact that part of the original had

been cut away, even if the central meridian of the part used were placed as nearly upright as possible; but on the maps in question the meridians are not shown, and there are no north-and-south lines long enough to have any perceptible curvature. Neither is there any horizontal lettering that had to be kept in the same position when the map was trimmed; and even if there was a legend in one corner it would be a simple matter to cut it out and place it in a new position.

A somewhat similar disregard for appearances is often exhibited by persons who use half-tone illustrations. It goes without saying that a rectangular photograph should have its horizon (if any) and all its vertical lines parallel to its edges, unless there is some special reason for treating it otherwise; but photographs several degrees out of plumb are very often published in text-books, scientific reports and magazines, even in some magazines which seem to take pride in the quality of their illustrations.

The principal cause of this rather annoying condition is probably in many cases too much division of responsibility. A traveler who makes photographs, especially if he is working for some institution which pays his expenses and furnishes the photographic material, often has them developed and printed without his personal supervision, by some human "machine" who treats all the views alike, no matter if some of them are a little out of plumb, as is almost certain to be the case, especially with snap-shots. When the time comes to supply illustrations for a manuscript the average author perhaps looks over his negatives, or a list of them, and gives orders for prints of certain ones, without noticing that some might be improved by judicious trimming, either to make the horizon level or to cut out superfluous portions. Then the editor, even if he notices that some of the prints need trimming, may be too busy to attend to it, or more likely not equipped with suitable apparatus, so he passes them on to the engraver, who naturally reproduces each picture just as it is, in the absence of instructions to the contrary.

The publication of such "eye-sores" can be so easily prevented by either author, editor or engraver that it should not be allowed to continue any longer. Of course in some cases, as in views of lakes and rivers, there may not be any distinct vertical or horizontal lines to guide the trimmer; but in such cases one may sometimes get his bearings by remembering that any point and its reflection in a body of still water are always in the same vertical line, except in the case of objects (such as birds) moving rapidly from the observer's right to left, or *vice versa*, and photographed with a focal-plane shutter traveling vertically.

ROLAND M. HARPER

UNIVERSITY, ALA.

ANOTHER SEX-LIMITED CHARACTER

TO THE EDITOR OF SCIENCE: From work done this spring on the inheritance of mammæ in swine, the writer has apparently discovered a new sex-limited character in the behavior of rudimentaries. These rudimentaries are the ones located low on the scrotum of the male, and well to the rear on the inside of the thigh of the female. The method of inheritance corresponds to the appearance of horns in Wood's crosses in sheep.

The males used by the writer both possessed rudimentaries on the scrotum and were heterozygous in nature if the interpretation is correct. Two ages of sows were used, gilts or sows just turned a year old, and sows that had just become two years of age. The results are depicted in the following table, the symbols being as follows: *R* equals factor for presence of rudimentary, *r* equals absence of same. *RR* equals rudimentaries in both sexes, *Rr* equals presence in male and absence in female, and *rr* equals absence in both sexes.

In the second table the deviation of the actual from the theoretical is wider than the writer would like, but is scarcely significant. The number of gilts are only seventeen and the average of pigs per gilt is less than with the sows. Both of these factors should complicate the results as to chance. Since there

is no appearance of rudimentaries where they are not expected the writer feels that the theory is justified in spite of the deviations.

SOWS MATED TO OLD BOAR (*Er*)

Gametic Composition Sows	No. Sows		Boars		Sows	
			Ab-sent	Pres-ent	Ab-sent	Pres-ent
<i>RR</i>	5	Expectation	0	26	11	11
		Actual	0	26	14	9
<i>Rr</i>	9	Expectation	9	27	36	12
		Actual	11	25	34	14
<i>rr</i>	18	Expectation	46	46	84	0
		Actual	48	45	84	0

GILTS MATED TO YOUNG BOAR (*Er*)

<i>RR</i>	4	Expectation	0	13	8	8
		Actual	0	13	13	4
<i>Rr</i>	5	Expectation	5	15	21	7
		Actual	7	13	18	10
<i>rr</i>	8	Expectation	19	19	23	0
		Actual	23	15	23	0

The gilts are from the sows listed in the first table and thus there are available three generations for study. The gametic composition assigned the gilts as a result of their behavior in breeding is confirmatory in every case of the composition assigned the sows.

The writer is not dogmatic in his interpretation and welcomes suggestions that may help reconcile the slight differences present.

AMES, IOWA

SCIENTIFIC BOOKS

Phylogeny of the Echini with a Revision of Palaeozoic Species. By ROBERT TRACY JACKSON. Memoirs of the Boston Society of Natural History, Vol. 7. Boston: Printed for the Society with aid from the Gurdon Saltonstall Fund, January, 1912. Quarto, 491 pages with 256 text-figures and 76 plates.

The discovery of the actual phylogeny of any group of animals involves not only the combined study of the morphology and development of those animals as they exist to-day, but also the more difficult and laborious study of their fossil remains. The true phylogenist

is seriously handicapped when he deals with a group, which is poorly represented in nature's great museum, the earth's crust, and happy is he if he can find abundant material in that wonderful storehouse. Doubly fortunate is he if his training enables him to get the most from such material. One of the greatest absurdities of our persistent and no doubt necessary tendency to classify men as well as objects is the grouping by themselves as "paleontologists" those who have had this training and who specialize in the study of fossil organisms. For if a man who uses as his material the long-dead and oftentimes badly preserved animals of our museums is a zoologist, is not the man who studies in the same way similar remains preserved in the strata of the earth, just as truly one? Do either the length of time since the death of the animal or the method by which its remains have been preserved matter? Perhaps a line might be drawn between those who study fossils simply as indicators of geological horizons having in view the history of the earth as an object by itself, and those who study them as the remains of living beings whose structure throws light on the problems of phylogeny, but the latter at least are zoologists (or botanists, as the case may be) and when they combine with their paleozoology thorough knowledge of the structure and development of Recent animals, they make the best possible phylogenists. When such a worker selects for study a small sharply-defined group with a rich geological history and abundant Recent material available, and devotes years of time and the most unflinching industry to his task, the results can not fail to be of prime importance to zoologists of all sorts, everywhere.

Few groups of animals are better adapted for such study than the echini. So sharply defined is the class that its ancestry is hidden in oblivion and not a single connecting link with any other class is known. There is no animal either Recent or fossil of which it can not be affirmed either "this is" or "this is not an echinoid." Moreover, the class is relatively small, only about five hundred living species being known with perhaps three times

as many fossil. The latter occur in all geological periods from the Ordovician to the Recent. Much of this material is beautifully preserved too, at least so far as essential structures go, for the hard test and lantern of a sea-urchin are exceptionally satisfactory objects for geological preservation. Finally sea-urchins have long been favorite objects of study, and their anatomy, development and life history are as well known as those of any marine invertebrates. If, therefore, the investigation be undertaken by the right man, the possibility of really working out the history of the group, were unusually favorable, and it is but the simple truth to say that in his "Phylogeny of the Echini" Dr. R. T. Jackson has shown himself to be that man. This monumental work sets forth the actual developmental and evolutionary history of the echini so fully, so fairly and so convincingly that it may be said with little fear of contradiction, there is no other group of animals of equal importance the main lines of whose phylogeny are more definitely and certainly known. Moreover so extraordinary is the amount of accumulated fact and so suggestive are the interpretations offered that there is something of interest in the volume for every one attracted by the problems of evolution, be he zoologist or botanist.

The book is dedicated most appropriately to Alexander Agassiz and Alpheus Hyatt, the former the Nestor of students of echini, the latter the originator or promoter of the principles and methods to which Jackson is himself so ardently loyal. Indeed the most striking characteristics of the volume are the emphasis placed on "stages in development" and the persistence with which the facts are marshalled in support of the "recapitulation theory." Those who deny the existence of stages and the validity of the recapitulation theory will find it exceedingly difficult, if not impossible, to meet the arguments and interpretations with which the writer defends his position. Second only to the emphasis on stages is the stress laid on variation and its significance. In the introductory pages, variations are grouped under five heads (*arrested*,

regressive, progressive, parallel, aberrant) and the meaning of each term is clearly explained. That variation is nearly always significant and that its significance may be determined are two cardinal principles which the reader of this book can scarcely doubt.

The terminology adopted by Jackson is as free from technicalities as possible and there are scarcely any new terms introduced. Those which are proposed, as for example "mid-zone," are simple, readily understood and meet a real need. In the case of such terms as have been used in different senses by previous authors, as "peristome," Jackson has adopted that usage which has appealed to him as simplest and least open to misunderstanding, and consequently even those who prefer a different sense can not mistake his meaning.

The extensive investigations which Jackson has made into the morphology of Recent echini have led him to some interesting discoveries of structures hitherto overlooked. A notable illustration of this is the presence or absence of pits in the upper end of the half-pyramids which compose the lantern. These pits have apparently been overlooked hitherto, though they seem to be of real systematic importance and even of ordinal value.

In his choice of generic and specific names Jackson has followed the International Code, but not at the expense of his judgment or common sense. As an illustration of his mental attitude, his sensible treatment of *Archæocidaris* vs. *Echinocrinus* is illuminative. Nobody questions that *Echinocrinus* has priority, but Jackson well says: "This name, however, is misleading, was based by Professor Agassiz on a misconception of affinities and has been abandoned for some sixty years in favor of the entirely appropriate *Archæocidaris* of McCoy. . . . To revive the old name *Echinocrinus* . . . will make confusion at present and in future, and no gain to any one." Another taxonomic snarl which Jackson has courageously untangled is that involving the name *Diadema*. For years it has been known that this name belongs to a cirriped, although it has also been in use for a genus of butterflies and for one of the best-known genera of tropical sea-

urchins. Students of the echini have persisted in its use and a family and an ordinal name based upon it are both universally adopted. Jackson's statement of the case (p. 27) is clear and convincing and his proposed substitutes *Centrechinus*, *Centrechinidæ* and *Centrechinoida* are appropriate and euphonious. Now that the Gordian knot is cut, it is to be hoped that zoologists will no longer use *Diadema* for either sea-urchin or butterfly.

Following his introductory pages, Jackson divides his book into three parts. The first of these is entitled "Comparative Morphology of Echini." It includes 168 pages, crowded with observations and interpretations of the typical structure of the test and lantern, and variations therefrom. One notes the absence of any discussion of the pedicellariæ and of the non-calcareous organs, but as these parts seem to have little phylogenetic significance the omission is perhaps not important. We may, however, hope that some zoologist will be moved to institute ere long a similar thorough comparative study of these less significant systems. So far as the pedicellariæ are concerned, Mortensen already has accumulated a mass of important material. Jackson's opening paragraph is a fine defense of the claim that paleozoology is only one aspect of zoology. Then follow sections on the form of the test, orientation, the pentamerous system and variation therefrom, the structure of the skeleton, growth, ambulacrum of the corona, interambulacrum, basiconal plates, imbrication, spines, peristome, ocular and genital plates, periproct, Aristotle's lantern and perignathic girdle. It is impossible in a review like this to give any adequate conception of the wealth of these sections; only the most striking features may be noted. The repeated references to Lovén and his work show in what high esteem he is held, while the constant emphasis on the significance of both normal structures and variations is very noticeable. Variants from pentamerous symmetry are shown to be exceedingly rare; only 25 were recorded prior to Jackson's work, but he has studied 71, of which 60 were found in the fifty thousand Recent echini personally examined by him.

He arranges these variants in twenty groups, showing that tetramerous specimens, though rarely completely symmetrical, are the most common. The study of both normal and variant tests led Jackson to the conclusion that the interambulacral plates are merely space fillers and always originate against the oculars. He therefore holds that the test of a sea-urchin consists, not of ten equally important areas, but of five only. Each of these is capped by an ocular plate, beneath which arise the two columns of ambulacral plates with one or more columns of space-filling interambulacra on either side. The growth of the test seems to take place chiefly on its outer surface. That the inner is more primitive is pointed out and demonstrated by interesting evidence. Much stress is laid on resorption of the calcareous matter during growth as a developmental factor, particularly in relation to the peristome. The matter of imbrication or non-imbrication of coronal plates is not considered to be of special phylogenetic importance. The covering of the peristome is carefully considered and six different types are pointed out. A new term, "non-ambulacral," is introduced in this connection, which is to be welcomed as accurate and useful; it is applied to those plates of the peristome which are not homologous with any of the coronal plates.

The section discussing the mutual relationships of ocular and genital plates occupies 79 pages and is one of the most remarkable contributions to echinoid morphology which has yet been made. With a patience and zeal most extraordinary, Jackson has personally studied fifty thousand specimens of 137 species of Mesozoic and Recent regular echini and has thus inspected, not hastily and casually, but with real care, a half million genital and ocular plates! Certainly results and opinions reached after such a study are worthy of more than ordinary consideration. The chief conclusions to which the author comes are as follows:

1. The position of oculars and genitals with reference to each other and to the periproct is not dependent on size or age in adults, but is a species character. Of course, like all

specific characters it is more firmly fixed in some cases than in others, but in only a very few cases is there any room for question as to what the species character in this particular is. From a purely taxonomic standpoint this discovery is of very great importance, but its chief interest lies in its phylogenetic bearings, upon which Jackson very properly lays particular emphasis.

2. In Recent regular Echini (except perhaps the Aspidodiadematidae) the oculars in very young individuals are all exsert (*i. e.*, not in contact with the periproct); they are shut out by the five genitals forming a closed ring. As the individual grows, however, one or more, even all, may become insert (*i. e.*, reach and touch the periproct) thus separating the adjoining genitals. The species character is, however, reached very early in life in most echini, when the individual is less than half grown, often when it is still but a few millimeters across. Even the variants which progress beyond the species character are found almost wholly among the small specimens. Exceptionally large and fine specimens generally show the species character.

3. Of the 32 possible arrangements of ocular plates with reference to the genitals, ranging from all exsert to all insert, only 22 were found and of these 14 were so rare that they all together characterized only about 1.5 per cent. of the specimens. The other eight have a very fixed and characteristic order of appearance. For example if two oculars only are insert in the adult, they are the two of the bivium (*i. e.*, oculars I., V.); if three, they are these two plus ocular IV., and if four, they are these three plus ocular II. The variations in this sequence are exceedingly interesting and important and are very fully discussed.

4. The first ocular to become insert appears to indicate a family character; it is usually ocular I., but in the Cidaridae, in the Arbaciidae and also in the Echinometridae it is ocular V.

5. While the very small apical system of the Echinometridae shows that a highly specialized family does not necessarily have a large apical disk, with oculars all insert, it appears to be

true that within any given family the most specialized genus, and within any genus the most specialized species, has the largest number of insert oculars.

Aside from these important general conclusions, mention should be made of the occurrence of what may be called "right-ocularized" sea-urchins in species which normally are "left-ocularized," i. e., some individuals have oculars I., V., II. insert, when I., V., IV. is the species character. Also deserving of special note are the remarkable peculiarities of the echini of the west coast of South America. Particular attention should be called to the invaluable tables on pages 100, 142, 143 and 154-164 and to the diagram (Fig. 176) on page 153. The detailed studies of the development of the apical disk in *Strongylocentrotus dröbachiensis* and of geographical variation in that species and several others, notably *Triploneustes esculentus*, deserve far more than the passing commendation possible here.

A discussion of the special characters of genital plates occupies pages 165-173, among the interesting points considered being the exclusion of genitals from the periproct, the fusion and splitting of genital plates, and the number and position of the genital and madreporic pores. The characteristics of the periproct occupy four pages and the very important point is emphasized that the so-called suranal plate is not a primitive but a secondary feature. More than twenty pages are filled with a discussion of the "Aristotle's lantern," including its muscles, and the perignathic girdle which is really a part of the same organic system. The pits, already mentioned, which were discovered in the tops of the half-pyramids of the Centrechinoida, are described here. Stress is laid on the importance of the structure of the lantern and teeth for purposes of classification and the Centrechinoida is divided into three very satisfactory suborders (*Aulodonta*, *Stirodonta*, *Camærodonta*) based primarily on these characters. The fundamental differences between auricles and apophyses are clearly pointed out and all the known varieties of each are discussed.

One finishes the reading of this first part of the volume with amazement at the array of facts it contains and with admiration at the way in which they are marshalled and the common sense with which the conclusions are drawn. There is no attempt to be startling and the newly discovered facts are not made the bases of wild hypotheses, but each theoretical conclusion is presented with the facts in support of it so fairly, so open-mindedly, as to carry great conviction.

To the taxonomist Part II., "Systematic Classification of Echini," which fills pages 199-234, will prove of particular interest. The author begins with a brief statement regarding his inability to accept Dr. Mortensen's divisions based on differences in the pedicellariæ and states the principles which have guided him. The recently suggested close relationship between echini and crinoids is emphatically disapproved, nor is any direct connection between sea-urchins and starfishes deemed at all probable. The original stock from which the echini have sprung is very likely to be found among cystoids. The "Key" beginning on page 201 includes all the orders of echini accepted or proposed by the author, all the families of regular Recent echini and all the families and genera of the Paleozoic era. This key is very fully elaborated, so that it is far more than the ordinary key. It might perhaps be called a synopsis, but as it is arranged in the customary dichotomous form it is very usable and will prove most helpful to all workers on either Recent or fossil echini. Nothing of the kind has hitherto been available and the need has often been sorely felt. On page 209 is given a remarkable "bird's-eye view" of the phylogeny of the echini as worked out by Jackson. This family tree well deserves most careful study and brings home to the reader certain fundamental conclusions of the author which may be briefly stated here. (1) *Bothriocidaris* is the nearest known approach to the primitive echinoid stock and serves as the root, or, perhaps better, the trunk of the tree. (2) The remaining characteristic Paleozoic forms are not in any sense ancestral to our modern

echini, but represent totally different branches which reach their culmination in the Permian. (3) The *Bothriocidaroid* stock was the origin of a *Cidaroid* branch, which in turn gave rise to the *Centrechinoidea*, and from this order all the other Recent echini have sprung. So firmly has Jackson grounded these conclusions on the facts of morphology, embryology and paleontology that it is difficult indeed to doubt their essential truth. Of course the time-honored divisions *Palæchinoidea* and *Euechinoidea* no longer have any use since they are artificial and unnatural.

Following the key are detailed accounts of each of the groups given therein. Part of this can not avoid being elaborated repetition, but there is added much that is important or suggestive, particularly concerning the interrelationships of the different groups. Great importance is very naturally given to the structure of *Bothriocidaris*, which is emphatically stated to be "the most primitive type of echini." Four new genera from the Paleozoic are described and their relationship to previously known forms is clearly brought out. The progressiveness of structure in the *Palæechinidæ* is emphasized and the ascending series is beautifully worked out, forming one of the most convincing demonstrations of "stages" imaginable. In this connection figure 237 on page 231 deserves special mention.

In Part III, "Paleozoic Echini," is to be found the more distinctively systematic and paleontological portion of Jackson's work, but it would be a great mistake for the phylogenist or student of variation to feel he could pass over this part superficially. It is crowded with details of morphology and of variation that are of very real importance. Besides forty species of *Archæocidaris*, most of which are based on fragments of spines or scattered plates, Jackson accepts eighty species of Paleozoic echini, grouped in 23 genera. Of these species, 22 are here described for the first time. The genera are grouped in eight families under four orders, but the *Perischoechinoidea* with four families includes all the characteristic Paleozoic forms, of which satisfactory

material is known, except *Bothriocidaris*. (The *Cidaroida* of course are not characteristic of the Paleozoic and the structure of the *Echinocystoida* can not be considered satisfactorily known.) After a brief introductory note there is an interesting chapter on "Geological Distribution" which will prove of particular interest to all who have little knowledge of paleozoology. Then follow the orders, families, genera and species in regular sequence for 208 pages. In view of its importance in Jackson's scheme, *Bothriocidaris* is again given particular attention. The very interesting fact is noted that this rare and extraordinary fossil was figured by Aldrovandus in 1618. Under the *Cidaroida* is given the description of a new species of *Miocidaris* from the Lower Carboniferous of Colorado. The discovery of this species is of the greatest interest and from Jackson's point of view of special importance. For the only argument against his phylogeny of the echini which presented serious difficulty was the apparent non-existence before the Permian of echini with only two columns of interambulacral plates. While appeal might have been made with perfect propriety to the "imperfection of the geological record," that last resort of all hard-pressed phylogenists, it is far more satisfactory to have this beautifully preserved cidarid as tangible evidence of the existence of the order so far back in the Paleozoic.

In the consideration of *Palæodiscus*, the extraordinary interpretation placed on its structure by Sollas and Spencer is rejected and a perfectly natural explanation is offered of the appearance which has led to the unfortunate belief that the fossil represents a sort of connecting link between sea-urchins and starfishes. To make his record of Paleozoic forms complete, Jackson has included some forty species of *Archæocidaris* largely based on fragments but he is the first to admit (pp. 256, 257) that most of these have little paleontological, less systematic and no morphological interest. Of the new genera *Hyattechinus*, with three remarkable species, two of them new, is the most noteworthy as it has the largest number of columns of interambulacral plates known

among echini and the form of the test is, in each species, unusual. The genus similarly named in honor of Lovén is less remarkable, but is of interest because it forms one of the steps in the progressive differentiation of the Palæechinidæ. In this series, *Lovénechinus* is intermediate between *Maccoya* and *Oligoporus*. Under *Melonechinus* (this name having to replace the more familiar *Melonites*, which is preoccupied) particular stress is laid on the support which the study of that genus with its fourteen species gives to the recapitulation theory. The last genus discussed, *Meekechinus*, is a new one and like *Hyattechinus* of special interest, but in this case it is the ambulacra which are highly specialized, having in each area twenty columns of plates. The teeth also are remarkable in being serrate. Altogether this striking Permian genus is a fitting climax to the remarkable series of forms beginning in the Ordovician with *Bothriocidaris*. While no one will question the right of Hyatt, Lovén and Meek to the honor Dr. Jackson has done them in connecting their names with these interesting echini, those of us who are utterly opposed to the mixing of honor and sentiment with taxonomy must regret that impersonal generic names were not preferred.

In compiling such a systematic monograph as is presented in Part III., one invariably finds forms so imperfectly described or so incompletely known that it is virtually impossible to determine their relationship to those better known. Jackson has very wisely gathered these unsatisfactorily known forms among Paleozoic echini under two heads, "Incertæ Sediæ" and "Nomina Nuda." Under the former are listed 35 species based on single plates, fragments of spines or incomplete and badly preserved tests. Many of these can be referred correctly to the family and some even to the genus, but, as their real relationship to the known forms can not be determined, it is a great advantage to have them listed in this way and not intercalated among the valid species where their dubious nature might easily be overlooked. There are eleven *Nomina Nuda* listed, of which *Hetero-*

cidaris keokuk and *lævispina* Hall have a curious history, here given by Jackson in full. A half a dozen unrecognizable fossils, three of which may be Cystoids, are listed under the heading "Paleozoic Forms incorrectly referred to Echini." A very full bibliography of 248 titles and an equally satisfactory index covering 17 pages complete the book.

A special word is demanded by the illustrations with which the memoir abounds and which are as fine as they are abundant. With four unimportant exceptions, every Paleozoic species accepted in the text is figured and of many species particularly the more important forms, both photographs and drawings are used to show the appearance and structure. Moreover a large proportion of the figures are from the type specimens. The morphology of the test and lantern of Recent species is lavishly illustrated and interesting variants are equally well shown. Particular attention should be called to the "summary figures," if such a term may be used, showing important morphological characters as they appear in different groups of echini. Of these, that on page 54 illustrating the features of the ambulacra, the one on page 80 showing the various kinds of peristome and that on page 184, which gives the different characters of lantern and teeth, are of particular importance, but the others on pages 70, 134, 148, 193 and 197 are really of no less value.

The chief fault of the book, if one must be discovered, would seem to be occasionally unnecessary reiteration. This is of course only an exaggeration of a virtue due to the author's desire to set forth his facts with perfect clearness and to marshal them in vigorous support of "stages" and the recapitulation theory. The same facts or group of facts are sometimes repeated in several different places, though usually from different points of view. This is in part due to the arrangement of the book, by which general morphology is discussed first and is followed by the application to taxonomy and the detailed study of the Paleozoic forms. Of course the latter sections necessarily contain a large amount of morphological detail involving considerable

repetition. But the fault seems to be due also to a fear that the reader will have forgotten or overlooked or misunderstood the significance of something the author considers of great importance. This desire to be perfectly understood leads to an exceptionally large number of references to plates and figures and to other passages in the text, so that the reading tends to become slow and laborious, or if the references be ignored, it tends to be superficial. In the explanation of the plates, the author's care for details is shown to a marked degree. It is safe to say one rarely sees a volume in which the explanatory text for the plates is so complete. So far as the statements or interpretations of facts are concerned, the author's freedom from obvious error and from ill-judged conclusions is really remarkable. In all his references to other workers, Jackson shows not only an open-mindedness and fairness of judgment, but a courtesy even in disagreement that is delightful. At the same time, there is no glossing over of mistakes in earlier publications, no matter whether made by himself or some other authority. The perfectly evident desire to know the facts as they really are wins the reader's confidence and the unusual freedom from ambiguity prevents any misunderstandings.

The typographical work reflects the greatest credit on the Cosmos Press, especially when one considers the numerous tables with percentages often worked out to two decimals and the abundance of scientific names and technical terms. That slips of the pen and occasional transposed letters should occur is inevitable; the extraordinary thing is how very few there are in this volume. Nearly all have been detected and gathered together on the page of "Errata and Addenda" which follows the index, but they are mostly so trivial as to be of absolutely no importance. On page 188, however, the phrase "distinct continuous base" carries no meaning and we are therefore glad to have the Errata explain that it should read "discontinuous base." On page 251, we are told by the Errata, the words "starfish" and "sea-urchin" have been trans-

posed in the author's discussion of *Paleodiscus*, an error which if uncorrected would seriously affect the argument. Two slips not noted in the "Errata," although not of great importance, may perhaps be worth pointing out. On page 121, in the footnote it is said that *Toxopneustes atlanticus* was described by Mr. Agassiz as *Leptechinus atlanticus*; the generic name should read *Lytechinus*. On page 238, the order Bothriocidaroida is inadvertently attributed to Jackson, 1896, whereas Duncan introduced the term in 1889.

When Alexander Agassiz's "Revision of the Echini" was published in 1872-74, it marked an epoch in the study of sea-urchins. It has literally been the foundation of all subsequent work throughout the world. It brought together and summarized the knowledge of echini as it stood at that time and much of the work it involved need never be done again. Jackson's "Phylogeny of the Echini" is a similar summing up of our knowledge to-day from the twentieth-century point of view and, like the "Revision," it marks an epoch. We are all to be congratulated that this fitting companion volume to the "Revision" is the work of an American zoologist; the Boston Society of Natural History is to be congratulated on the publication of a memoir of such unusual merit; and Dr. Jackson himself is most of all to be felicitated on the production of such a profound and masterly piece of research.

HUBERT LYMAN CLARK

The Parasitic Amæbæ of Man. By CHARLES F. CRAIG, M.D., Captain, Medical Corps, U. S. Army. 1911. J. B. Lippincott Company. Pp. 253. \$2.50.

This book has no doubt been welcomed by many medical men, for it brings together the scattered literature in a complex field. In making such a compilation it is natural, perhaps, that the author should be biased by his own investigations. However, it is unfortunate that this fixed attitude should be so much in evidence throughout a work the purpose of which is to aid medical men in their studies of amœbic infections. A more critical

and less positive method of presentation would have increased the value of the work.

On the whole, the descriptive portions of the work, covering the morphology, biology, classification, nomenclature and species of parasitic amœbæ, are excellently executed and well illustrated.

A firm belief in the stability of the parasitic species *Entamœba histolytica*, *E. coli* and *E. tetragena* and the ease with which they may be differentiated on morphological grounds, provided one has studied them long enough, is made evident by the author. In the historical review it is said that Councilman and Lafleur gave "a most excellent description of the parasite now known as *Entamœba histolytica*." This is done in spite of the admission that comparatively recent researches have shown that species determination must rest mainly upon a knowledge of the reproductive cycle. Again, the author is not very consistent in including in his list of unquestionable species half a dozen organisms the life cycles of which have been only incompletely studied.

No adequate discussion is made of the possible adaptability of amœbæ to a parasitic existence, although on *a priori* grounds one would suspect that some such process might still be taking place in nature. The answer to this question is evidently of the greatest importance from the standpoint of the prophylaxis of amœbiasis. The only extensive experiments made to adapt amœbæ to a parasitic existence have been performed by Musgrave and Clegg in Manila. In criticizing the experiments performed by these investigators the author is rather indefinite and dismisses the importance of their work from the reader's mind by stating that "while lesions were undoubtedly produced by the mixed cultures of amœbæ and bacteria, the authors could not, with their methods, be sure of excluding the spores of *E. histolytica* or the encysted forms of other amœbæ pathogenic to the animals used in their experiments" (p. 63). Later (p. 66) he lays stress upon the feeding of "pathogenic bacteria" along with the cultivated amœbæ—in spite of the fact that it is well known that the typhoid bacillus and

cholera spirillum are not pathogenic when fed to the species of monkey used (*Macacus cynomolgus*). Certainly one can not criticize the cultures of amœbæ used by Musgrave and Clegg, for these were the descendants of a single amœba growing in "pure mixed culture" with a single species of bacterium. If it is argued that their animals were infected naturally either before or after the experimental feedings, then it must be shown that spontaneous amœbiasis is of such frequent occurrence in monkeys in Manila as to render these animals worthless for experimental purposes.

Again this state of mind is exhibited in discussing the cultivability of the parasitic amœbæ: "What I have always believed and stated, *i. e.*, that the parasitic amœbæ of man have not been cultivated" as Craig says, he believes to be supported by the recent work of Whitmore, who took cultures he obtained in Manila to Hartmann's laboratory and found them all to be free living species. Yet he makes no mention of the work of Fantham, whose article is quoted in his bibliography, to the effect that, by special cultural methods, he was able to identify two cultures obtained from Manila and kept on Musgrave and Clegg's medium, as *Entamœba coli*.

UNIVERSITY OF CINCINNATI

BOTANICAL NOTES

BOTANY BY THE EXPERIMENTAL METHOD

A GOOD many years ago some of us introduced to American colleges the laboratory method of learning about plants and this brought about a revolution in botanical teaching mostly for the better, but not wholly without some distinct losses. It is doubtful, for example, whether the pioneers in the laboratory method in this country ever contemplated the total abandonment of field work which followed in some places. It is pretty certain that they intended to *add* the laboratory method to the existing methods of study, which included the textbook, the field and the herbarium. Certain it is, however, that many teachers supposed that the adoption of the laboratory

method was to be followed by an abandonment of everything that had been done in the past. This was a serious error of judgment, and has led to no end of wasteful educational experiments. Because the laboratory method is good in one place is no proof that it is good in all. When I want to learn all that I possibly can of a new country I visit it if I can do so, and see all that I can of it, but I do not hesitate to use maps and read books pertaining to the country. I may even ask the people who have lived there longer than I to tell me all that they know. In this way I build up my knowledge of the country, and it is good and reliable, far more so, perhaps, than if I had relied wholly upon what I could have seen personally.

And so it is in botany. I must surely see as much for myself as possible, but life is quite too short for me to hope to see all that is known with my own eyes. Here and there, at critical and strategic points, I must see for myself and then I can go a long ways, when I must again get my reckoning by an observation. The mariner does not sail the seas by doing nothing but make mathematical observations. It would be slow sailing indeed were he to do so.

And yet this is just what some of the book-makers are planning to have the children do. They are to learn everything about plants by the experimental method. They lose sight of the fact that there is no special saving grace in the labor of making experiments. We make experiments on plants in order that we may learn botany; we do not learn botany in order to make experiments on plants. Let every teacher remember that useless experiments involve as real a waste of time as dawdling or idling. I can walk from Lincoln to Denver, but it takes so much time that it will pay me far better to be carried there on a railway train.

All this is suggested by Mr. Payne's "Manual of Experimental Botany" (American Book Company), whose purpose, the author tells us, is "to teach botany by experiment." In two hundred and twenty-eight "experiments" and "exercises" the pupil is led over

and into and among a great many facts pertaining to plants. Some of these exercises will prove to be interesting and helpful to pupils, but there are so many of them that it is quite impossible for the pupil to perform them with any care. It would have been far better to have selected a much smaller number, and to have placed them properly in a scheme outlining the subject. That would have introduced the pupil to the science of botany, i. e., to an organized system of knowledge of plants. As it is, the child will have spent a great deal of time and energy in the making of experiments not definitely correlated, nor organized into a science. The pupil will have the results (more or less accurate) of a considerable number of experiments, but they will not constitute botany, that is, the science of botany, and it may be doubted whether in this unorganized form they will have any educative value. It would not be a bad thing to use this book as a store from which to draw such experiments as the teacher and pupil might wish to use in going systematically over the field of botany, although in some cases we must warn the teacher that the experiments will not "prove" all that they are supposed to demonstrate (e. g., 130, 131, 132, 139, 145, 148, etc.). On the other hand, many of the experiments are well planned, and will prove interesting and instructive.

A HANDFUL OF LITTLE MANUALS

It would seem that the solution of the problem of a handy manual for field work in systematic botany is to be reached by the compilation of little books covering restricted areas, or even confined to limited portions of the year.

Several years ago Professors Clements, Rosendahl and Butters brought out a little pamphlet of 40 pages entitled "Guide to the Spring Flowers of Minnesota," which has been well received by the schools of the state, and to this they have added a "Guide to the Trees and Shrubs of Minnesota," "Guide to the Ferns and Fern Allies of Minnesota" and "Guide to the Autumn Flowers." In the

same series we have also "Minnesota Mushrooms," by Professor Clements.

A year ago A. O. Garrett, of the Salt Lake City High School, published a little book of 106 pages, entitled "Spring Flora of the Wasatch Region," and including "the eastern edge of the Great Basin as far south as Manti" (central Utah). This is now followed with a second, considerably enlarged edition of 139 pages. It must be very useful to pupils in the schools of the region covered. It would be still more helpful if not confined to "spring plants" alone ("before June 15").

Much like the last is the "Spring Flora of the Intermountain States," by Professor Dr. Aven Nelson, of the University of Wyoming (Ginn), which in 202 pages covers Colorado, Wyoming, Montana, Idaho (excepting the northern part), a portion of eastern Oregon and the northern half of Utah. The treatment is much like that in the Wasatch Flora, and must be equally useful in the much larger region included. Here again one wishes that the "spring" limit could be removed.

Hall's "Yosemite Flora" (Elder, San Francisco) is a book designed to appeal in paper, pictures and binding more to the tourist than to the pupils in schools, and yet it must prove a most inspiring field manual for pupils fortunate enough to have access to its keys and descriptions. While called a Yosemite Flora, we are told that it is also "designed to be useful throughout the Sierra Nevada Mountains." Eleven most artistic plates and 170 text figures add much to the usefulness of the book for the beginner.

The "Flora of Nebraska," published by N. F. Petersen, instructor in botany in the Louisiana State University, is an attempt to name every plant (conifers and flowering plants) growing without cultivation in the state. It is modeled after Rydberg's well-known "Flora of Colorado," and like it the treatment is by the copious use of keys, by means of which the phyla, classes, orders, families, genera and finally the species are successively found. And after the species is determined by this method one finds a little paragraph assigned to it containing habitat,

distribution and locality data. It will be useful to high-school pupils, in spite of the rather numerous typographical errors, due to the employment of a printer unaccustomed to scientific printing.

Here may be mentioned Professor Schaffner's "Key to the Families of Seed Plants" designed to aid his students (Ohio State University) to distinguish the natural plant families by carefully devised keys.

BOTANY IN THE MOUNTAINS

The University of Colorado Mountain Laboratory at Tolland, Colo., will hold its session this year, beginning June 24 and ending August 2, 1912. There will be a general course in field biology, in which both animals and plants are considered in relation to their environment, and also courses in systematic botany, ecology and biology of ponds and streams. Special attention will be given to research work.

The laboratory is situated in an interesting region at an altitude of nearly 9,000 feet. Tolland is the station for Boulder Park, a mountain valley surrounded by timber-clad hills. Within easy reach of the laboratory are typical pine and spruce forests, mountain meadows, narrow canyons, glacial lakes and alpine tundra. In addition to regular daily field trips which take the student to these various habitats of animals and plants there will be all day excursions by rail to the foothills and even to the plains for the purpose of making comparative studies of the flora and fauna of these localities. Professor Francis Ramaley, of the University of Colorado (Boulder), is the director of the laboratory.

THE UNIVERSITY OF NEBRASKA

SPECIAL ARTICLES

NITRATES IN SOILS¹

THE fertilizing value of materials that we now know to contain nitrogen was of course

¹ Paper read by invitation before the Society of American Bacteriologists at Washington, December, 1911.

recognized very early, though nitrogen was first recognized as a distinct element in 1772 by Rutherford.

Later it was demonstrated that nitrogen is an element indispensable to life, present in all organisms and the mass of literature, scientific, popular and commercial, concerning nitrogen in its various forms and their relation to plant growth is overwhelming to the student.

Yet, notwithstanding the long period of time during which we have recognized the importance of nitrogen, the aggregate of many life times that have been devoted to its study or the thousands of pages that have been published concerning its relation to plants, there still remain some of the most fundamental questions for solution.

The universality of nitrogen in plants is well authenticated. The amounts removed from the soil by a few leading crops are as follows:

Corn (45 bushels per acre)	63 lbs.
Cabbage (15 tons per acre)	100 lbs.
Clover hay (2 tons per acre)	82 lbs.
Wheat (15 bushels per acre)	31 lbs., etc.

Not only is it present, but it is indispensable, as has been repeatedly shown by careful water- or sand-culture experiments. Just how and why nitrogen is essential is a much more difficult question. It is a necessary element in the composition of protoplasm, and many other organic substances. It aids in the assimilation of other needed elements, and in photosynthesis. These functions of nitrogen would account for the need of a certain amount of available nitrogen in soils used for crop production. But it is found that soils with apparently an abundance of available nitrogen for the supply of many crops are benefited by the addition of still more nitrogen. Various theories which we will not enter upon here further than to point out that nitrogen or its compounds may serve other uses than by being merely absorbed or absorbed and assimilated have been proposed to explain this peculiar fact. What these other uses are is one of the large questions, as yet barely disclosed.

Whatever other uses nitrogen may serve, that of a food element is unquestionably a preeminent one, and it is with this phase of the nitrogen subject alone that I shall deal.

Admitting the importance of nitrogen in assimilation the next question is: "In what forms is nitrogen available to the plant?" This, as has been the fate of many questions in biology, received its emphatic answer years ago, an answer that asserts itself convincingly through thousands of popular and scientific articles and text-books, but one which seems to be founded on very insecure evidence and one which is likely to be largely modified as research progresses.

The popular, almost the universal conception of available nitrogen is expressed in some such words as these, which are taken from prominent texts by famous authors and mostly from recent works.

The majority of farm crops can use only that part of the nitrogen in the soil that is present as nitrate¹ and on a later page:

The plant can make use of the nitrogen only in the form of nitrates.

The nitrates are the chief source of the nitrogen supply of green plants.²

Sulphate of ammonia . . . must be nitrified before the nitrogen is available to plants.³

The conversion of the ammonia formed during the process of putrefaction into the nitrates is a matter of greatest importance in soil fertility. . . . A soil to encourage nitrification must, then, have suitable basis. The question of soil fertility is, then, in its last analysis a bacteriological problem.⁴

This conception of nitrates has inevitably focused attention on nitrates as a soil factor of preeminent, of indispensable importance. It makes them appear so valuable that their coming and going are of superlative import and their failure to attend to spell disaster.

The subject assigned to me is "Nitrates in

¹ Vivian, 1909.

² Bergen and Davis, "Principles of Botany," pp. 233.

³ Percival's "Agricultural Bacteriology," p. 142.

⁴ Frost and MacCampbell, "General Bacteriology," 1910, p. 288.

Soils." I shall consider this subject under several heads as follows, setting aside purely physical and chemical phenomena and limiting myself to the biologic aspects of the question.

The origin of nitrates in soil nitrification and nitratation.

The destruction of nitrates in soil denitrification.

Methods.

The actual importance of nitrates.

Nitrification consists in the conversion of ammoniacal nitrogen into nitrites then nitrates, processes shown by the classic work of Winogradsky to be dependent on two separate groups of bacteria, the nitrite and the nitrate bacteria. Winogradsky's work has been abundantly confirmed and is not to be questioned. And so far as we know yet all nitrification results from this dual activity, the several reports that have been made of direct nitratation of organic nitrogen or of ammonia by bacteria lacking proper confirmation.

Ammonia is thus essential to nitrate formation and ammonification of organic nitrogenous substances is an essential preliminary step. Ammonifying bacteria are of numerous species, indeed some years ago in my laboratory a long search for soil bacteria that could not ammonify ended in failure. Ammonification in the light of present knowledge appears to be an absolutely essential process in the circulation of nitrogen, but the need is amply met and in no soil that I know of, and we have ourselves examined many hundreds, is there any actual deficiency in ammonifying power.

Recently the Rothamsted Station has attributed low yields to low ammonifying power due to consumption of ammonifying bacteria by predatory protozoa. This condition may exist in exceptional cases, but that it is in any wise general is not probable.

Nitrifying organisms have generally also been assumed to be present practically everywhere and in ample numbers. The results of a Bacterial Soil Survey conducted in my own laboratories and about to be published show that this assumption is not warranted. In a large per cent. of the soils tested the N.E.

was very low. It appears, therefore, that while a deficiency in ammonification is not to be feared there may be instances, perhaps many of them, where the amount of nitrification falls below that of the nitrogen equivalent of a good crop. Why nitrification is vigorous in some soils and very poor in others is not known. In some instances it may be referred to unfavorable acidity, moisture, etc. Many cases are due to causes as yet unknown. That abundance of organic matter does not inhibit nitrification was clearly demonstrated in our own experiments, in which vigorous nitrification occurred in pure cow manure.

On the other hand, an exceptional case of injury from too great nitrification has recently been reported by Sackett.

Denitrification is the destruction of nitrates. It is brought about by many species of bacteria and may result in reduction of nitrates, to ammonia, various oxides or even to free nitrogen. This is unquestionably a detrimental process if it proceeds below the ammonia stage. The conditions necessary to denitrification are usually stated to be the proper organisms, moisture and organic matter. The organism is conceded to be commonly, almost universally present. Yet the fertilizer formulae of the chemist and agricultural teacher usually call for an admixture of nitrates with dried blood, cottonseed meal, etc., thus surely furnishing ideal conditions for denitrification. Theory here opposes practise and as yet no decisive experiments have shown which is correct.

Methods.—I can not refrain in passing from referring to the absolute necessity in soil bacteriological work of making the tests in soils and not in solutions. Winogradsky found that in solutions organic matter inhibited nitrification. From this he and others have generalized that it does so in soil, a conclusion that is far from the truth, as our experiments have conclusively shown.

THE ACTUAL IMPORTANCE OF NITRATES

In all of the foregoing discussion we have assumed that nitrates are the necessary or at

least by far the most readily utilized form of nitrogen. The vast amount of research carried on in many laboratories regarding the processes of nitrification and denitrification indicate that these phenomena are regarded as of high significance and nitrogen of superlative value. Is this so?

Nitrogenous organic matter may be classified as proteids, albuminoids, amides and alkaloids. The larger part of the organic nitrogen in soils probably consists of acid-amines and amino and amino-acids.

To what extent may these or their degeneration products, particularly ammonia, serve as plant food?

A few years ago most special students and perhaps all general writers would have said that these substances must undergo nitrification before they are available to plants. Today, without much evidence, perhaps without any evidence that will stand searching criticism, there is a tendency among some writers to hedge on this point and to speak of ammonia as well as nitrates as possessing available nitrogen. We even hear the term "active nitrogen" embracing ammonia and nitrate nitrogen.

The evidence on this question is too voluminous to bring before you, but we may summarize it something as follows:

Innumerable experiments have been made bearing upon the relative availability of nitrate and ammonia nitrogen to plants. Most numerous of such have, of course, been field tests of ammoniacal compounds and of nitrates drawing conclusions from the yield or the crop analyzed. Such tests are manifestly inconclusive, since in all cases the question of nitrification in the soil is an ignored factor and it is not in reality known whether the ammonia that is applied to the soils is used as such or is first nitrified or indeed whether the reverse may not be true, viz., that the nitrates have been reduced to ammonia and utilized in that form. The general conclusion that can be drawn from such experiments is that ammonia applied to soils does not, with most crops, on most soils, give so large crop returns as do nitrates. The common ratio of

utility is generally given as something like 60 or 70 to 100. This conclusion varies, however, for different crops, different soils, different times; and such experiments are far from giving a solution of the fundamental question.

Another line of attack is by means of water-culture experiments. Many such lack bacteriological control and the conditions regarding nitrification are not known. A few have been conducted with rigid bacteriological control and do actually prove that a plant can assimilate ammonia without its previous nitrification. Such tests, however, do not simulate field conditions much more closely than would experiments on the habits of squirrels parallel nature if conducted in aquaria. Our results of comparative tests of the functions of bacteria in soils and in solutions have given us entire lack of faith in such abnormally conditioned experiments.

Again, plants have been grown in sterile soils under aseptic conditions, with constant and rigid chemical and bacteriological control. Such results may properly pose as qualitative. But they are not quantitative, because of necessity they are conducted on but a few plants and the factor of individual variation is so great that quantitative results are vitiated unless a sufficiently large number of plants be used to reduce the coefficient of error to something like a negligible quantity. Also the conditions of control involving abnormal radiation, ventilation, etc., are unsatisfactory.

Jost says:⁵

Many hundred culture experiments in water and sand have established the fact that nitric acid forms an excellent, not to say the best possible source of nitrogen for the great majority of plants. (How the divergent results arrived at by Treboux (1905) are to be explained it is, as yet, impossible to say.)

The recent comprehensive researches of Pitsch (1887-1896) and of Mazé (1900) have conclusively proved that the nutritive value of ammonia must not be entirely denied; in the majority of green plants it is second only to nitric acid in value.

⁵Jost's "Plant Physiology," pp. 134 and 135.

In the case of some plants, particularly maize and other Gramineæ, ammonia is by no means of inferior value to nitric acid, for Mazé was able to obtain as great an increase in dry weight in maize, using at most a one half per cent. solution of ammonium sulphate, as when he supplied it with a solution of a nitrate. Similar results were obtained in cultures of *Brassica* and species of *Allium*. Forest trees also must be dependent on ammonia, since nitrates are seldom present in woodland soils.

So far as we know at present it is quite certain that in addition to plants which definitely prefer nitric acid (*e. g.*, buckwheat, potatoes, turnips) there are others which get on just as well or even better with ammonia.

Perhaps after all the most conclusive proof that plants in nature can do well without nitrates comes from the fact that certain peat soils have been shown to be devoid of nitrates, yet they amply support plant growth. Again, rice responds well to ammonia even in soils where no nitrification can be detected.

Also it is true that we, as well as other investigators, have shown that soils very low in nitrification may be very productive and that on such soils plants respond readily to organic matter or ammonia, indicating that nitrification is often not an essential factor to soil fertility.

The general conclusion regarding the availability of ammonia and nitrate-nitrogen is that both can be used by many plants; that often nitrate nitrogen applied in the field gives larger crop yields. But the relative availability of these nitrogenous substances for crop plants under natural conditions has not yet been determined. This is an essential desideratum. A question that must be answered conclusively before we can know the significance of nitrification and denitrification.

It seems after all that ammonification is the essential thing and that nitrification is relatively unimportant, but this is only indicated, not proved.

There is need of rigid proof as to the relative availability to each crop plant of ammonia and of nitrate nitrogen. Then we shall know the true importance of the problems of nitrification and of denitrification. Following

this knowledge will come the questions of correcting such evils as need correction, the heightening of nitrifying power in cases where this is low and where higher nitrification would be of advantage; the lowering of denitrification if this be a disadvantage and where it is a disadvantage.

Plant physiology must join hands with soil bacteriology to ascertain which are the significant problems that conditions of deficiency may receive correction.

F. L. STEVENS

COLLEGE OF AGRICULTURE,
MAYAGUEZ, PORTO RICO

REACTIONS OF YOUNG LOBSTERS DETERMINED BY FOOD STIMULI

IN recently glancing through some old notes written several years ago, when the writer was interested in problems relating to the behavior of the larval lobster (*Homarus americanus*), certain unpublished data regarding the reactions to food-stimuli came to light. It is the aim of the present note to give some of these data, which may be regarded as supplementary to the material published in 1908,¹ terminating the writer's investigations on the subject of behavior of *Homarus*.

Many students of animal behavior have learned that the condition of hunger is able to greatly modify the reactions of organisms to many stimuli—especially to food. Generally speaking, it has been found that hunger prevents the manifestation of certain normal types of reaction. The effect of hunger upon certain stages of *Homarus* is no exception to this rule. In this instance, however, the condition of hunger has been thus far found instrumental in modifying the reactions of the lobster only in the fourth and later stages, for similar experiments upon lobsters in the earlier stages have not yet been made. One reason for this is the fact that the larval lobsters of the first three stages are not able to direct their own activity in a definite direc-

¹ "The Behavior of the Larval and Early Adolescent Stages of the American Lobster (*Homarus americanus*)," *Journ. Comp. Neurol. and Psychol.*, 1908, 18, (3), 199-301.

tion, as toward food; and it is not until the fourth stage is reached that the lobster can be truly said to be master of its own movement. It was learned in the early stage of the investigations on the behavior of the fourth-stage lobsters that, if any study at all was to be made of their reactions to light, the lobsters must first be fed—and well fed. For, if such was not the case, the tendency to eat one another usually annihilated any possible manifestation of a response to the influence of light or other stimuli. Even if the condition of hunger did not excite these extreme cannibalistic instincts, and so preclude all experimentation, it produced a manifestation of unrest which made any results in the way of numerical counts impossible. As has been shown in earlier papers, the fourth stage-period, at least in the early part, is typically a “swimming-period”—the “swimming-period” *par excellence* of the lobster's whole existence. It is not until the latter part of the fourth stage-period that the lobster, under the proper conditions of environment, goes to the bottom and begins to burrow in the sand or under the bits of shell. Now it was found that the condition of hunger appeared to have a very definite influence upon the time at which this burrowing “instinct” was first “liberated” in the fourth-stage lobster. To determine this point, several experiments were performed of which the following is a fair example of all.

Experiment A

Influence of Hunger on “Burrowing.”—On August 5 about thirty early four-stage lobsters were taken from one of the confinement bags, in which they were being reared. They did not show much evidence of hunger and were therefore isolated for 48 hours without food. At the expiration of this time, all proved to be very hungry. Now two groups of five lobsters each were taken from this lot, and each group was placed in a 14 cm. crystallization dish, the bottom of which was covered with sand, gravel and shells. Immediately after this, one group of lobsters was fed with chopped clam meat; the other group was

left hungry. The dishes were then placed on the laboratory table, and records were taken frequently to ascertain at what time the burrowing would be first manifested; and in which group of lobsters—the fed or the unfed. For some little time the members of both groups swam more or less constantly at or near the surface. Further records, which show the time of burrowing of the individuals in the two groups, may be presented as follows:

Time	Group Fed	Group Unfed
Aug. 7, 10:00 A.M.	1 larva burrowed.	5 larvæ swimming or crawling.
Aug. 7, 11:30 A.M.	2 larvæ burrowed.	5 larvæ swimming or crawling.
Aug. 7, 3:30 P.M.	3 larvæ burrowed.	5 larvæ swimming or crawling.
Aug. 8, 9:00 A.M.	4 larvæ burrowed.	5 larvæ swimming or crawling.
Aug. 9, 9:00 A.M.	4 larvæ burrowed.	3 larvæ burrowed.*
Aug. 9, 6:00 P.M.	4 larvæ burrowed.	4 larvæ burrowed.

These results appear to show that hunger may postpone the liberation of the burrowing instinct, while satiety appears to favor its early appearance. One other experiment, and the converse of the previous case, may be introduced.

Experiment B

Influence of Food-stimulus upon Surface-swimming in the Fourth-stage Lobsters.—In this case about twenty mid and late fourth-stage lobsters were placed in a glass jar 25 cm. in diameter filled with salt water to a depth of 10 cm. These lobsters were kept without food until they showed evident signs of hunger. All the lobsters remained on the clean bottom of the jar, over which they crawled or lightly swam. Occasionally one would come to the surface, only to leave it again for the bottom of the jar. Now a long pipette was partly filled with fresh clam juice, and the outside of the pipette carefully washed to take away all possible trace of clam odor

* At this point in the experiment one of the five lobsters was killed and eaten by the others, three of which immediately burrowed.

from the surface of the tube. When the lobsters were found to be resting quietly on the bottom of the dish, the point of the pipette was slowly lowered to the very bottom of the jar, where a few drops of clam juice were liberated in the vicinity of the fourth-stage lobsters. Within a few seconds all the lobsters in that region rose immediately to the surface of the water and swam wildly about for a variable length of time, after which they again went to the bottom of the jar. Here they either rested permanently or, if a sufficient amount of the clam juice remained near the bottom of the jar, apparently restimulated, the lobsters manifested further surface-swimming. These same tests were tried on the fifth-stage lobsters, but, although the clam juice might excite them to more active crawling over the bottom of the jar, it never produced surface-swimming, as in the case of the fourth-stage lobsters. These observations have received further support from the facts which the writer once learned from Dr. V. E. Emmel. It appeared in his case that the hungry lobsters with which he chanced to be working, when stimulated by a piece of clam meat dropped into their confinement bottles, would not remain on the bottom to enjoy the morsel, but would rise to the surface and manifest active swimming for some moments. These few observations demonstrate clearly that the lobsters, at least of a certain age, respond very definitely to certain kinds of food-stimuli. To what extent this kind of reaction may be responsible for the surface-swimming so characteristic of the early fourth-stage lobsters under natural conditions it is difficult to say. It is not improbable, however, that, after the fast which usually accompanies the approach of the third moulting-period the great hunger which characterizes the early fourth-stage lobster may be, in part, at least, the cause of the surface-swimming, although, as has been shown in previous publications, the reaction to light is also no doubt an influential factor.

SOCIETIES AND ACADEMIES

THE ANTHROPOLOGICAL SOCIETY OF WASHINGTON

THE 458th regular meeting of the society was held in the new National Museum at 4:45 P.M. on February 6. Professor Mitchell Carrell presented a paper entitled "The Excavations at Knossos or Labyrinth of Minos," illustrating his talk with the lantern.

ON February 20 the retiring president, Dr. J. W. Fewkes, made an address on "Great Stone Monuments in History and Geography," at eight o'clock in the new National Museum. Dr. Fewkes's paper will appear in full in the Smithsonian Miscellaneous Collections.

THE 459th regular meeting of the society was held in the new National Museum at 4:45 P.M. on March 12. Miss Densmore read a paper on the "Sun Dance of the Teton Sioux." This paper was based upon a study of the sun dance made among the Teton Sioux on the Standing Rock reservation in North Dakota and represents the sun dance usage in that band of the tribe. The study was conducted in a series of councils to which the old leaders of the tribe came from a radius of about a hundred miles. Fifteen reliable men were selected to give the account of the sun dance, their authority being established by interviews with about forty members of the tribe, in widely separated localities. Those who took part in the sun dance councils were men who bore upon their bodies the scars of their participation in the sun-dance tortures, and among them were the man who acted as intercessor in the ceremony and the man who "did" the cutting of those who fulfilled vows, both men being the only Teton living who had performed these official acts. The men comprising the sun-dance council, with the writer and an interpreter, visited the site of the last sun dance held by the Teton Sioux in 1882, the site being identified by the Indians. The place where the sun-dance pole was erected, the outline of the "shade-house" and the location of the "sacred place" were recognized and measurement showed them to be correct, according to the usual plot of the sun-dance grounds.

The sun dance was held annually by the Sioux and was distinctly a religious ceremony. The fulfilling of vows of torture was an important part of the ceremony, the vows having been made by men in danger on the warpath. When making the vow they asked

for a safe return and that they might find the members of their family alive and well, and the fulfillment of the vow was required whether the prayer was granted or denied.

The paper was illustrated by songs of the sun dance which had been recorded by the phonograph and were played on the piano. Many of these were ceremonial songs and known only to the man who sang them for the speaker. One of these men has died since the songs were recorded. A collection of old ceremonial articles used in the sun dance was also exhibited.

THE 460th regular meeting of the society was held April 10 at 4:45 P.M. in the new National Museum. The speaker of the afternoon was Professor Pittier, who delivered an address on "Notes on the Native Tribes of Panama," with all of whom he came in contact in the course of his travels.

There is much confusion current as to the number of the so-called tribes and the stocks to which they are related. The numerous names recorded correspond in fact not to distinct tribes, but merely to villages, names of chieftains, or, in a general way, to what the old Spanish chroniclers used to design as "parcialidades."

In the present time there are east of the Canal Zone only two distinct "nations," viz., the Cunas, or Cuna-Cuna, to which the San Blas Indians belong, and the Chocoos to the south, beyond the Tuira River. The line that separates these two stocks is at the same time the ethnological boundary between South and Central America.

The Cunas are a very numerous and strong race, almost uniformly of short stature and broad shoulders. They are very jealous of their independence and shun all interference on the part of strangers, including the Panamanian government, the authority of which over them is only nominal. The Cunas of the northern coast, east of Nombre de Dios, or San Blas Indians, are far above the other Panamanian aborigines in their social and economic development; they constitute one of the best elements of the population included in the territory of the young republic, being thrifty and enterprising and having made of their extensive coconut palm plantations a real source of wealth. The remaining Cunas, known as Bayanos, Chucumenes, and Bayas, live in the interior and are less advanced, the two former groups being acknowledged as real "Indios bravos." All speak one language, with slight local variations.

The Panamanian Chocoos are but the northernmost branch of a numerous stock which extends more or less continuously along the Pacific coast of South America, from Punta Gracine in Darien, to the Ecuadorian boundary. In the Sambú Valley, where Professor Pittier found them, they are a happy lot, usually tall and well built, scantily clothed and living quite near to nature.

West of the Canal Zone, in the mountains of Veraguas and eastern Chiriqui, live the polygamous Guaymies, once under the care of the Spanish missionaries, but who have long since gone back to their own independent life and customs. They do not, however, avoid or repel the contact with the other natives, and owing to the rapid expansion of the neighboring populations, so-called civilized, the Guaymies are doomed to soon lose their characteristics and individuality as a race. Certain ethnological traits, as well as their physical appearance, point to a relationship with Costa Rican tribes.

In consequence of what Professor Pittier calls a "caprice of arbitration," the Republic of Panama has acquired the northern branch of the Terrabos or Tirúb of Costa Rica. These dwell in small and rapidly dwindling numbers at the headwaters of the Teraria or Tilorio, the main branch of the Changuinola River. They have been investigated by Pittier in the course of his survey of Costa Rica.

These four are the tribes represented to-day in Panama. The Dorasques, supposed by some to descend from the great Chiriqui pottery makers, seem to have disappeared, unless the Brunka of Costa Rica are really what is left of them.

With reference to the possible affinities of the Panamanian tribes with the neighboring stocks, the speaker took absolute exception to the theory of the Chibchan relationship, which he was one of the first to advocate about twenty years ago and which has since received general acceptance under the authority of Brinton, Deniker and others. The pretended relationship is founded merely on linguistic analogies and on the apparently common origin of quite a number of words. But these facts can be taken as conclusive only if supported by anthropological common characteristics and also by partial community of uses and customs. Physically, the Cunas are strikingly distinct from the Guaymies and the Costa Rican Indians, and both stocks offer none but general racial likeness with what is left of the original Chibchas.

In the opinion of Professor Pittier the origin of the Cuna-Cuna has to be looked for elsewhere than in the interior of Colombia, and the Guaymies, Valientes, Bribri, Térrabas, Sumos, etc., are more likely to be the remnants of a primitive autochthonous stock. Pittier's talk was illustrated by numerous lantern slides and the exhibition of the objects collected among the Choceos and Guaymies.

TRUMAN MICHELSON,
Secretary

THE BOTANICAL SOCIETY OF WASHINGTON

THE 81st regular meeting was held at the Cosmos Club, May 7, 1912, at 8:00 P.M. President W. A. Orton presided. Twenty members were present.

The following papers were read:

Further Studies on the Pecan "Rust": F. V. RAND.

A preliminary report on the fungus causing this pecan leaf disease was published in *Phytopathology* for August, 1911, under the name *Mycosphærella convexula*. Since that time the fungus in question has been obtained from a number of other sources and several strains known to have originated from single two-celled ascospores have been under study. In the course of one and one half year's growth in culture, strains originally producing a majority of apparently two-celled ascospores have gradually changed, until now most of the ascospores are distinctly non-septate. Furthermore, a typical *Glæosporium* form was developed in culture and also obtained from the host. A large number of colonies known to have originated from single ascospores or single conidia all gave cultures producing both perithecial and conidial forms, showing the two to be different phases in the life cycle of the same fungus. Inoculations on Jonathan and Yellow Newton apples gave a decay similar to bitter-rot, with production of conidia and immature perithecia on the latter. Inoculations on young pecan leaves under greenhouse conditions gave negative results, but infections together with production of conidia and mature perithecia, readily occurred on living leaves in a damp chamber. From the studies summarized above it would appear that the fungus is closely related to if not identical with *Glomerella rufomaculans*, and that it is not a very active parasite on the pecan.

Distribution of Pigment in the Seed-coat of the Cowpea: Dr. ALBERT MANN.

Transverse sections of the seed-coat disclose three principal layers of cells: an outer palisade

layer, a heavy-walled layer below this of empty cells, and a layer of considerably compressed cells with long axis parallel to the surface of the cowpea.

It was found that the colorations in the cowpea are the result of pigments deposited in two of these layers. In all colored cowpeas there is a basal color or practically uniform tint and invariably to be found in the lowest of the three layers, which the speaker terms the basal color layer. This is a melanin compound of an orange-yellow tint, grading into lemon-yellow and pale buff. All other colors are obtained by superposing upon this basal color layer various pigments, and these are uniformly deposited in the palisade cells, and as a rule in the lower and larger third of the cell cavity. Three colors are found here: black to blue-black, or sometimes purple tint, which is an anthocyanin, a yellow or brassy-brown pigment and an intense black pigment, the last two being melanin compounds. By various arrangements of these three superposed tints in the palisade cells, or by the absence of any pigments in these cells, the various schemes of coloration in the cowpea are obtained; the marbling, blotching, dotting, as well as the uniform colors of some cowpeas, being produced by the basal color plus such superposed arrangements of color in the palisade cells as are characteristic of the different varieties.

In the case of the few cowpeas having white or colorless seed-coats, the result is obtained by the suppression of all pigments both in the basal color layer and in the palisade layer.

A wild cowpea secured from North Nigeria, Africa, is of particular interest, in that upon the same cowpea all the elements of color, as well as all the schemes of coloration are to be found.

The Purpling Chromogen of the Hawaiian Bitter Yam: H. H. BARTLETT.

Illustrations of the Phytogeography of the North American Continent: Dr. JOHN W. HÆRBERGER (by invitation).

The speaker displayed to the society an album of twelve volumes of photographs and illustrations of North American vegetation, collected during the preparation of his recently published work on the phytogeography of North America. The source of the material and method of preparation and classification were discussed, and the general plan and scope of the work were explained in detail.
